VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate. The hospital contains 60 beds and 12 at the home at Margate, and has a large out-patient department (over 500 weekly). Physicians: Dr. Julian Evans and Dr. Ridge Jones. Physicians to the out-patients: Drs. Albert Venn, T. Colcott Fox, F. D. Drewitt, and Henry Philpot. Surgeons: Messrs. Pick and Clutton. Surgeons to the Out-patients: Messrs. Churchill and Walter Pye. Dental Surgeon: Mr. Francis Fox. House-Surgeon: Philip D. Turner. Registrar: Paul F. Molina. Secretary: Captain W. C. Blount, R.N. Out-patients are seen daily as under: Medical cases: Daily at 9 A.M.; also on Mondays and Thursdays at 1.30. Surgical cases: Daily, except Wednesday and Saturday, at 9.30 A.M. Dental cases: Saturdays at 9 A.M.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Consulting Physicians: Dr. Robert Barnes and Sir Andrew Clark, Bart., M.D. Consulting Surgeon: Mr. Buxton Shillitoe. Consulting Ophthalmic Surgeon: Mr. George Cowell. Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, and Dr. H. Radcliffe Crocker. Surgeons: Mr. Arthur Cæsar, Mr. R. W. Parker, and Mr. L. A. Dunn. Assistant-Physicians: Dr. J. A. Coutts and Dr. Dawson Williams. Administrator of Anæsthetics: Mr. Thomas Bird. Medical Officer: Mr. J. Scott Battams. Secretary: Mr. Ashton Warner. Miss F. A. Davies, Lady Superintendent; Mrs. Fisher, Matron.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 100 beds. In 1885 there were 1269 in-patients and 14,933 out-patients under treatment. There are appointments for a House-Physician and two House-Surgeons, with board and residence, tenable for six months. Also appointments for a limited number of Clinical Assistants. Physicians: Drs. G. Goddard Rogers, D. W. C. Hood, and F. G. D. Drewitt. Physician for Diseases of Women: Dr. Albert Venn. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and W. Bruce Clarke. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant-Physicians: Drs. W. P. Herringham, J. B. Ball, and Seymour Taylor. Assistant-Physician for Diseases of Women: Dr. J. A. Mansell Moullin. Assistant-Surgeons: Messrs. C. A. Ballance, H. F. Weiss, and B. Wainewright. Assistant-Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Surgeon-Dentist: Mr. H. L. Albert. Pathologist: Mr. H. P. Dunn. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Secretary: Mr. R. J. Gilbert.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physician: Dr. W. S. Playfair. Consulting Surgeons: Sir Prescott G. Hewett, Bart., and Mr. W. Morrant Baker. Physicians: Drs. Fred. Taylor, James F. Goodhart, Nestor Tirard, and Fred Willcocks. Surgeons: Messrs. H. G. Howse, R. Clement Lucas, C. J. Symonds, and G. H. Makins. Ophthalmic Surgeon: Dr. W. A. Brailey. Dental Surgeon: Mr. R. Denison Pedley. House-Surgeon: Dr. Albert Martin. Hon. Secretary: Dr. I. Dobree Chepmell.

ALL SAINTS' CHILDREN'S HOSPITAL, 4, Margaret-street, and 59, Mortimer-street, W.—Founded by the All Saints' Sisterhood in 1882 for Chronic Joint Diseases. Twelve beds for boys and eight for girls under the age of ten years. Surgeon, Mr. Noble Smith.

MR. THOMAS COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, SURGERY, &c.—This school is intended to meet the requirements of three classes of students: 1. Qualified practitioners and advanced students—i.e., gentlemen wishing either to obtain some of the higher qualifications, or to compete for appointments in Her Majesty's Army, Navy, and Indian Medical Service. 2. Students preparing for the usual Primary and Pass Examinations of any of the licensing bodies. 3. Beginners entering upon their medical studies, either by a short term of apprenticeship, or under the new regulations of the Examining Board in England. Both rapid advanced classes, complete in three months or less, but still thoroughly practical, are provided; and also, as required, more elementary classes of six months' duration. The instruction is given on the dissected and undissected body, with normal and pathological specimens, microscopical preparations, chemical, physiological, and surgical apparatus, splints, &c. The operations of surgery are performed by the students on the dead body. Private address: 40, Brunswick-square.

SOUTH LONDON SCHOOL OF PHARMACY.—This school was established in 1868, and removed to the present premises in 1875. Owing to the expiration of the lease of the old premises, it has recently been joined by the analytical and general science teaching branches previously carried on at Kennington-cross, and the whole institution is now consolidated under one roof, so bringing every department under the continuous and direct control of the director, Dr. John Muter, M.A., F.C.S., F.I.C., who personally delivers the lectures on Chemistry, Physics, and Botany, and superintends the laboratory instruction. The department most valuable to medical students is the Medical and General Science Tutorial Department. The subjects taught are:—For Matriculation, &c.: Elementary Chemistry. For First B.Sc. and Preliminary Scientific: Inorganic and Practical Chemistry. For First M.B.: Organic Chemistry, Analysis, and Pharmaceutical Chemistry and Materia Medica. For Apothecaries' Hall and Royal Colleges of Physicians, London and Edinburgh: Chemistry, Botany, and Materia Medica. For Pass M.B. Lond: Practical Toxicology and Forensic Medicine. Students attend by special arrangement, and perpetual or time fees may be had from the Secretary, 325, Kennington-road, London, S.E.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Lectures on Botany and Materia Medica by Professor Bentley, M.R.C.S. Eng., F.L.S.; Chemistry by Professor Dunstan, F.C.S.; Practical Chemistry, Professor John Attfield, Ph.D., F.R.S., F.I.C., F.C.S., Director of the Laboratories; F. W. Short, Demonstrator; E. J. Eastes, Assistant-Demonstrator; Practical Pharmacy: Joseph Ince, F.L.S. The session commences on Friday, October 1st, at 9 A.M. Medical students, or pupils intending

to enter the medical profession, are admitted to the lectures and to a course of practical chemistry of any length in the laboratories. Application for admission to the School, or for further information, may be made to the professors or their assistance in the lecture theatre or laboratories, 17, Bloomsbury-square, London, W.C.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

BATH ROYAL UNITED HOSPITAL.—120 beds. Honorary Consulting Physician; Dr. Coates. Honorary Physicians: Drs. Goodridge, Cole, and Fox. Honorary Surgeons: Messrs. Stockwell, Fowler, and Freeman. Honorary Medical Officers for Out-patients: Dr. Field, Messrs. Cowan and Craddock. Honorary Assistant-Surgeons: Messrs. Green, Scott, and Ransford. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Culliford-Hopkins. The hospital is recognised by the Royal College of Physicians, Surgeons, &c., and licensed for dissections. It contains a library and an excellent museum, in which are a large number of interesting specimens, both in Pathology and Comparative Anatomy. Fees for attendance—twelve months, £10 10s.; six months, £5 5s. Instruction in Practical Pharmacy, £5 5s. Number of patients admitted during the past year, 1054; out-patients 8256. Operations performed, 156. Anæsthetics recorded, 148. For further particulars, apply to the registrar and curator.

QUEEN'S COLLEGE, BIRMINGHAM.—The Sands Cox Prize, of the value of £20, is offered annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. The examination for this prize in 1886 will be held in the last week in March. Two Ingleby Scholarships will be offered annually after examination in Obstetric Medicine and Surgery, and Diseases of Women and Children. The Scholarships are open to students who have completed the first two years of their curriculum in this College. One or more Sydenham Scholarships will be offered annually, of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. The Scholarships are held for three years, subject to good behaviour. One or more Queen's Scholarships will be offered annually of the value of 30 guineas. They are held for three years, one-third being paid each year, subject to good behaviour. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. Students of Queen's College are qualified to compete for all scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.—*General Hospital.*—Consulting Physician: Dr. Fletcher. Consulting Surgeons: Mr. Crompton and Mr. Baker. Physicians: Drs. Wade, Foster, Rickards, and Saundby. Surgeons: Messrs. Pemberton, Bartleet, Jolly, and Chavasse. Obstetric Officer: Dr. Malins. Assistant-Physicians: Drs. Simon and Foxwell. Assistant-Surgeons: Messrs. Haslam and Barling.—*Queen's Hospital.*—Consulting Obstetric Surgeon: Mr. Berry. Consulting Surgeon: Mr. S. Gamgee. Physicians: Drs. Sawyer, Carter, and Suckling. Surgeons: Messrs. Furneaux Jordan, Wilders, Bennett May, and Lloyd. Obstetric Surgeon: Mr. A. F. Hawkins. Ophthalmic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims. Physician for Out-patients: Dr. Hogben. Casualty Surgeons: Messrs. Clay and Marsh.

MASON COLLEGE, BIRMINGHAM.—Founded 1875. Opened 1880. The session will commence on October 1st. Instruction is given in Arts and Science, and students are prepared for the various examinations of the University of London. Entrance and other Scholarships are offered for competition. This College is associated with Queen's College, Birmingham, for the purposes of medical education, all students of the latter College attending in the Physical, Chemical, Botanical, and Physiological Departments of Mason College. The Library contains upwards of 17,000 volumes. A syllabus containing full information as to the various courses of instruction, fees, &c., will be forwarded on application to the Secretary.

BRISTOL SCHOOL OF MEDICINE (affiliated to University College, Bristol).—Students can complete in Bristol the entire course of study required for the Medical and Surgical Degrees of the University of London, and for the Diplomas of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given at University College, Bristol, are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; while the Medical School, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the above examining boards. All necessary information may be obtained from the dean of the Bristol Medical School, Dr. Markham Skerritt.

BRISTOL ROYAL INFIRMARY (instituted 1735).—264 beds. Physicians: Drs. Spencer, Shingleton Smith, Wald, and Shaw. Surgeons: Messrs. Board, Dowson, Prichard, Greig Smith, and Harsant. Ophthalmic Surgeon: Mr. Cross. Assistant-Physician: Dr. Prowse. Assistant-Surgeon: Mr. Paul Bush. House-Surgeon: Mr. Dacre. House-Physician: Dr. Swain. Assistant House-Surgeon: Mr. Thurston. Secretary: Lieut.-Colonel Graham.

Scholarships and Prizes: Two Entrance Scholarships, 35 guineas and 10 guineas, awarded annually in October, after examination in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clarke Prize, 15 guineas; Crosby Leonard Prize, 7 guineas; Tibbitt's Prize, 9 guineas; three Pathological Prizes, 3 guineas each.

Dressers reside in the house in weekly rotation, and have charge of all casualties under the supervision of the house-surgeon. Special instruction (including dresserships) for first-year students in the out-patient department. Class instruction in the wards by the physicians and surgeons on four days a week, in addition to the regular clinical lectures. Clinical Clerkships and Dresserships, 5 guineas for each six months. Special departments for Diseases of Women, the Eye, Ear, &c, with Clerkships and Dresserships attached. A Pathological Clerk is appointed every four months, who performs all post-mortem examinations. The large museum and well-stocked library are arranged and managed for the advantage of students.

Further information can be obtained from Dr. Spencer, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—164 beds. Physicians: Drs. Markham Skerritt, Harrison, and Baron. Physician-Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Dobson, Keall, and Pickering. Dentist: Mr. Parson. House-Surgeon: Mr. Stephens. Physician's Assistant: Mr. Barker. Assistant House-Surgeon: Mr. Morton. Clinical Clerkship, six months, £5 5s. Dressership, six months, £5 5s. Obstetric Clerkship, three months, £3 3s. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women, and in Dental Surgery. Further information may be obtained of the secretary, at the hospital, or from Dr. Markham Skerritt, Dean of the Hospital Faculty.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Clinical lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. Lewis Shapter and H. Davy. Consulting Surgeons: Messrs. A. Cumming and T. W. Caird. Surgeons: Messrs. Bankart, Harris, Dounville, and Bell. House-Surgeon: Dr. Blomfield. The hospital contains 214 beds (including special children's wards). There is a good library and museum, dissecting and post-mortem rooms. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. For further particulars as to fees, &c., apply to the house-surgeon.

WEST OF ENGLAND EYE INFIRMARY, EXETER.—Surgical Staff: Messrs. Bankart and Tosswill. Registrar: Mr. Roper. The Infirmary contains fifty beds. Arrangements can be made for students of the Exeter Hospital to attend the practice of the Eye Infirmary.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:—A University of Durham Scholarship, value £100, for Proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value £15, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value about £35, for Medicine. The Gibb Scholarship, value £25, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value about £15, for Clinical Medicine and Clinical Surgery. At the end of each session a Silver Medal and Certificates of Honour are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, two Prosectors, and two Assistant Physiologists are elected yearly. Two Pathological Assistants, two Assistants to the Dental Surgeon, and one Assistant in the Eye Department, are also elected every three months. Medical and Surgical Assistants, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-ON-TYNE INFIRMARY.—Physicians: Drs. Philipson, Drummond, Oliver, and Limont. Surgeons: Drs. Arnison, L. Armstrong, Hume, and Mr. Page. Assistant-Surgeons: Mr. T. A. Dodd and Mr. Williamson. Pathologist: Dr. Drummond. Dental Surgeon: Mr. E. Fothergill. House-Physician: Mr. J. Waldy. House-Surgeon: Dr. G. W. Ridley. The infirmary contains 280 beds. There are special wards for the treatment of Children, and for Ophthalmic and Syphilitic Diseases. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given as opportunity offers by the Pathologist. Practical Midwifery can be studied at the Newcastle Lying-in Hospital, where there is an out-door practice of about 300 cases annually. Lectures are given on Psychological Medicine at the Coxlodge Lunatic Asylum by Dr. R. H. B. Wickham, Medical Superintendent. A Special Course of Instruction is given in the Hospital for Infectious Diseases by the Superintendent and City Officer of Health, Dr. H. E. Armstrong.

GENERAL KENT AND CANTERBURY HOSPITAL.—Open for the reception of patients April 26th, 1793. 48,692 in-patients and 86,963 out-patients have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society, for £7 7s. Operation day, Thursday, 11 A.M. Consulting Physician: Dr. Alfred Lochee. Physician: Dr. Henry Alex. Gogarthy. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Charles Holttum, Frank Wacher, T. Whitehead Reid, and John Greasley. Dentist: Mr. Martin L. Bell. House-Surgeon: Mr. Z. Prentice. Assistant House-Surgeon and Dispenser: Mr. William P. Barrett. Secretary: Mr. Charles H. Read. Over 700 in-patients, 3000 out-patients, and 1000 dental cases are attended in a year.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 320 in-patients, surgical and medical, and during the last year 4401 in-patients and 24,600 out-patients were treated; these numbers show a remarkable increase, if compared with statistics of ten years ago, when only 11,500 out-patients were seen. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in the operating-room. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are being organised. The Public Dispensary, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students.

The Leeds Medical School, now the Medical Department of the Yorkshire College, occupies a central position in the town, close to the General Infirmary, and a few minutes' walk from the new buildings of the Science and Art Departments situated in College-road. The present premises were built specially for the purposes of a medical school, and the teaching in purely medical subjects is there given. The teaching in Chemistry and Physics, Practical Chemistry, Practical Toxicology, Biology, and Botany is given in the College-road buildings, the lecture-rooms and laboratories of which are amongst the most commodious in the kingdom. The accommodation for teaching comprises all the conveniences necessary for the various branches of study. All the other courses required by examining boards are given by Professors and Lecturers. The Museums and Library offer special advantages. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students:—Resident medical officer, resident surgical officer, resident obstetric officer, appointed for twelve months and eligible for re-election. Two house-physicians, holding office for six months; four house-surgeons, for twelve months; twenty-four physicians' clerks, for three months; twenty-four surgeons' dressers, for six months; eight ophthalmic and aural surgeons' dressers, for three months; eight gynæcological ward clerks, for three months; eight gynæcological out-patient clerks, for three months; twenty-four assistant-physicians' clerks, for three months; twenty-four assistant-surgeons' dressers, for three months; forty-eight dressers in the casualty room, for three months; twelve post-mortem room clerks, for three months.

UNIVERSITY COLLEGE, LIVERPOOL, MEDICAL FACULTY: VICTORIA UNIVERSITY.—The Infirmary attached to the School contains 300 beds, with 40 special beds for the treatment of Diseases of Women. Lock, Lying-in, and Eye and Ear Hospitals are in the immediate vicinity, and their practice is open to the students of the Medical Faculty.

The composition fee for lectures and classes is 60 guineas, which may be paid in two equal instalments with an interval of twelve months; and for hospital practice 40 guineas, which may be paid in the same way.

Two house-physicians and three house-surgeons are appointed from the qualified pupils every six months, also clinical clerks, dressers, and post-mortem clerks.

Two Holt Tutorial Scholarships, each of the value of £100 are awarded annually by the Medical Faculty to senior students. Also an entrance Lyon Jones Scholarship of £21 for two years for students proceeding to the Victoria Degree, and another of the same value, open to all students who have completed their second year. The Derby Exhibition of £15 for Clinical Medicine and Surgery. The Torr and Bligh Gold Medals for Anatomy and Physiology, and the class prizes. During the past year the new Chemical Laboratories have been opened, and the old building added to the Physiological Department. The only changes on the staff are the appointment of Mr. Edgar Browne, as lecturer on ophthalmology, Dr. Hope as lecturer on Hygiene, and Dr. Ross as Demonstrator of Anatomy.

LIVERPOOL NORTHERN HOSPITAL.—150 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Hamilton, Little, and Paul. Senior House-Surgeon: Dr. F. H. Wigmore. Junior House-Surgeons: Mr. J. R. L. Dixon and Mr. W. C. Helme. 200 beds. Clinical Lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships are open to all students. Special wards for accidents and diseases of children. Resident students received.

NORFOLK AND NORWICH HOSPITAL.—150 beds. One year's attendance recognised by examining boards. Fees: For the physicians' practice, 5 guineas for six months. For the surgeons' practice, including dresserships, £10 for three months; £15 for six months; £20 for one year; £30 for two years. Pupils resident and non-resident. Physicians: Sir Peter Eade, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Crosse, and Mr. Williams. Assistant-Surgeons: Dr. Beverley and Mr. Robinson. House-Surgeon: Mr. H. Chester Nance.

NORTHAMPTON GENERAL INFIRMARY.—Established 1743; rebuilt 1793. In-patients, 1693; out-patients, 8223. Beds,

144. Physicians: Dr. Buzzard and Dr. Jones. Surgeons: Messrs. G. H. Percival and R. A. Milligan. House-Surgeon: Mr. W. E. Audland. Assistant House-Surgeon: Mr. St. John O. Rands. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica, and Practical Pharmacy. Pupils' fee £25 per annum, or a perpetual fee of £50.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Physiology, Pathology, and Materia Medica, a great extension of the school buildings has been made. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the infirmary by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy by the different members of the staff of the medical school and infirmary. The following scholarships and prizes are open to students of the medical school:—1. A Dauntesey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any medical school in the United Kingdom, and whose age does not then exceed twenty-five years. The subjects of examination are—(*a*) General and Comparative Anatomy; (*b*) Physiological Botany; (*c*) Chemistry; (*d*) Mathematics or Latin. 2. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 3. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology, and has passed a satisfactory examination in Physiology. 4. Two Platt Exhibitions of the value of £15 each, to be competed for by first and second years' students in the class of Physiology. 5. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 6. Medical and Surgical Clinical Prizes, each of the value of six guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY.—Consulting Physicians: Drs. R. F. Ainsworth, Frank Renaud, H. Browne, and Sir Wm. Roberts. Consulting Surgeons: Mr. Geo. Bowring and Mr. Lund. Physicians: Drs. Henry Simpson, John E. Morgan, D. J. Leech, and J. Dreschfeld. Assistant-Physicians: Drs. James Ross and Graham Steell. Obstetric Physician: Dr. Lloyd Roberts. Surgeons: Messrs. F. A. Heath, Walter Whitehead, Thomas Jones, and James Hurdie. Assistant-Surgeons: Messrs. Fred. A. Southam and G. A. Wright. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Resident Medical Officer: Dr. Malcolm Webb. Resident Surgical Officer: Mr. Joseph Collier. Medical Registrar: Dr. J. S. Bury. Surgical Registrar: Mr. W. Thorburn. Pathological Registrar: Dr. Thomas Harris. Assistant Medical Officers: Drs. S. Moritz and A. T. Wilkinson. General Superintendent and Secretary: Mr. W. L. Saunder.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including 28 for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Special classes are held for clinical instruction on Saturday afternoons during the winter months. Out-patients are seen daily at 9 A.M. at the dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. During 1885 there were 1220 in-patients and 9649 out-patients under treatment at the dispensary.

RADCLIFFE INFIRMARY, OXFORD.—This infirmary is open to students for Medical and Surgical work in the wards and out-patients' departments. Clinical lectures are given by the Litchfield Clinical Lecturer in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis and Surgical Manipulation. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination, or the 1st Oxford M.B.

SHEFFIELD SCHOOL OF MEDICINE.—The Infirmary contains 180 beds, a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. A tutor's fee of £2 2*s.* is required from students entering for Anatomy and Physiology.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—Hon. Acting Medical Officers: Dr. Keeling, Mr. F. Woolhouse, Mr. R. Favell, and Mr. A. H. Laver. The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and in case of need are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the Hospital, and be supplied with cases of midwifery. House-Surgeon: J. M. Willey. Secretary, H. B. Warner, 39, George-street.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 200 patients, including children's wards, and special ovarian wards. In-patients last year, 1660; out-patients, 9299. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians and Medical Officers: Drs. J. T. Arlidge and C. Orton, and Messrs. Ashwell and J. G. West. Surgeons: Messrs. W. H. Folker, J. Alcock, and W. D. Spanton. Dental Surgeon: Mr. A. W. Whittingham. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees &c. may be obtained.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Founded 1848. Beds, 224. A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at 11 o'clock, and practitioners are welcomed.

YORK COUNTY HOSPITAL. Established 1740; rebuilt 1851. 116 beds. In-patients, 948; Out-patients, 6383. Consulting Physician: Dr. W. Matterson. Physicians: R. Turner, M.B., and R. Petch, M.B. Consulting Surgeon: Mr. W. D. Husband. Surgeons: Messrs. R. Hewetson, W. H. Jalland, and F. Shann. Dental Surgeon: Mr. W. Glaisby. House-Surgeon: Mr. E. F. Morris. Assistant House-Surgeon: Mr. Thomas Burt. Secretary: Mr. R. Holtby.

SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London and Dublin, and the other Medical and Public Boards. In accordance with the Statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be attended in this school, each of which *anni medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for any class, taken for graduation in Edinburgh, shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Fees.—For a first course of lectures, £3 5*s.*; for a second, £2 4*s.*; perpetual, £5 5*s.* To those who have already attended a first course in Edinburgh the perpetual fee is £2 4*s.* Practical Anatomy (six months' course), £3 3*s.*; course of demonstrations, £2 2*s.*; perpetual, £4 4*s.* Practical Anatomy with course of demonstrations, £4 4*s.* Practical

Chemistry, £3 3s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy, Diseases of the Ear, Diseases of the Skin, Diseases of Children, and Diseases of the Tropics and Climatology, each £2 2s. Vaccination, £1 1s. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Practical Medicine and Medical Diagnosis, each £2 2s. Insanity, £1 1s.

EDINBURGH SCHOOL OF MEDICINE AND PHARMACY, Marshall-street, Nicolson-square.—The classes of this school will be resumed for the winter session on Oct. 19th. Chemistry, Midwifery, Surgery, and Medicine. From the Dispensary attached to this institution, Pharmacy, Practical and Theoretical, Practical Midwifery. Out-door Practice, Medical and Surgical Diagnosis. Attendance at this institution qualifies for the University of Edinburgh and all other licensing boards. Tutorial classes in all the branches of the medical curriculum. Preliminary Medical Classes, 11 A.M. to 4 P.M., and in the evening; Theoretical Chemistry, 10 to 11 A.M.; Theoretical Midwifery, Dr. C. Bell, 11 to 12 A.M.; Theoretical Pharmacy, R. Urquhart, 3 to 4 P.M.; Class for Medical Diagnosis, 2 to 3 P.M.; Class for Surgical Diagnosis, 3 to 4 P.M. Practical Midwifery and Out-door Practice at the Edinburgh Provident Dispensary, 2 to 4 P.M., under the supervision of Drs. Bell, Robertson, Wylie, Matheson, Jamieson, and Price; Practical Pharmacy, 2 to 4 and 7 to 8 P.M.; Practical and Analytical Chemistry, 9 A.M. to 5 P.M. The Pharmaceutical Section of this School will open on Oct. 4th. Particulars of R. Urquhart, Secretary.

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, and Larynx. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, also to cases of Incidental Delirium or Insanity. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 2s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the pathological department are appointed by the pathologists.

ANDERSON'S COLLEGE, GLASGOW.—The following courses are given, which qualify for all the licensing boards:—In winter: Anatomy, Chemistry, Physiology, Surgery, Medicine, Materia Medica, &c. In summer: Midwifery, Medical Jurisprudence, Botany, Hygiene, &c. The Chemical Laboratory is open daily from 10 to 5. Students of the College are admitted to the practice of the Ophthalmic Institution on payment of a matriculation fee of 5s.

Fees.—Each course of lectures (except Anatomy), first session, £2 2s.; second session, £1 1s.; afterwards free. Anatomy (including dissecting-room), first session, £4 4s.; second session, £4 4s.; third session and perpetual, £1 1s.; summer (including Practical Anatomy), £1 11s. 6d. Practical Anatomy only, £1 1s.; Osteology, £1 1s. Students who have attended classes at other schools will be admitted to such classes as they may have attended elsewhere at reduced fees. Fees for all the Lectures and Hospital Practice required of candidates for the diplomas of Physician and Surgeon, £48.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—The winter session will open on October 26th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures and demonstrations are also given on Public Health, Practical Physiology, Operative Surgery, Aural Surgery, Dental Surgery, Diseases of the Eye, and of the Throat and Nose. During summer lectures on Insanity are given by Dr. A. Robertson, in the City Asylum under his charge.

Class Fees.—For each course, first session, £2 2s.; second session, and perpetual, £1 1s. Anatomy: First winter session, £4 4s.; summer session, £1 11s. 6d.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 11s. 6d. per session. Lectures on Diseases of the Ear, £1 1s.; with clinique to those not students of the hospital, £2 2s. Dental Dispensary free to students of the hospital; to others, £5; first year, perpetual, £10. Lectures on the Eye, £1 1s.; other special courses free.

GLASGOW ROYAL INFIRMARY.—Number of beds, 542. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of Venereal Diseases and the Diseases of Women, whilst Diseases of the Skin, Eye, Ear, Throat, and Teeth are specially treated at the Dispensary. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons; instruction in Pathological Anatomy and Histology is given by the pathologist.

Appointments.—There are four physicians' and six surgeons' assistants. These appointments are free, and can be held for twelve months; they are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students without additional fee.

Fees for Hospital Practice and Clinical Lectures.—First year, £10 10s.; second year, £10 10s.; afterwards free. For six months, £6 6s.; three months, £4 4s. Vaccination certificates, £1 1s.

GLASGOW HOSPITAL AND DISPENSARY FOR THE DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Thursdays, and Fridays, at 2 P.M., by Dr. Barr and assistants; and operations and special demonstrations to students and practitioners take place on Thursdays from 3 to 4 P.M. Adam Sutherland, 75, West Nile-street, Secretary.

GLASGOW WESTERN MEDICAL SCHOOL, University-avenue, Hillhead.—The winter session will open on October 26th. The school is situated close to the Western Infirmary, where students obtain their Hospital Practice and Clinical Lectures. To accommodate the increasing number of students, the dissecting rooms (during the vacation) have been entirely rearranged and enlarged. The attention of students is directed to the unusual facilities presented for the study of Practical Anatomy and Operative Surgery, the supply of subjects being practically unlimited. The dissecting-rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow in accordance with the regulations, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of lectures, first session, £2 2s.; second session, £1 1s. Students who have attended a first course elsewhere pay £1 1s. Anatomy, including Practical Anatomy, £4 4s. Summer session, £1 11s. 6d.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Cutaneous Affections. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students may attend whichever they select at the beginning of the session. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department a systematic course is given in the winter and a practical course in the summer; these are likewise recognised by the University for graduation. Eight resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second years; for six months, 7 guineas; and for three months, 4 guineas. Secretary: Henry Johnston, 125, Buchanan-street, Glasgow.

GLASGOW HOSPITAL FOR SICK CHILDREN, situated at Garnet-hill, was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 57 beds for non-infectious cases only.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street.—40 beds. Clinical and systematic course of lectures for students during the winter and summer sessions.

ABERDEEN ROYAL INFIRMARY.—Contains about 250 beds. Consulting Physician: Dr. A. Harvey. Physicians: Drs. J. W. F. Smith-Shand, R. Beveridge, and Angus Fraser. Surgeons: Messrs. A. Ogston, Ogilvie, J. O. Will, and R. J. Garden. Ophthalmic Surgeon: Dr. Alex D. Davidson. Dental Surgeon: Dr. Williamson. Resident Superintendent and Apothecary: Dr. T. Collins. Treasurer and Secretary: Mr. W. Carnie.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains about 580 beds. Consulting Physician: Dr. Robert Jamieson. Clinical instruction is given to students during three months in summer.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Eight Junior Scholarships have been founded in the Faculty of Medicine, of the annual value of £25 each. Two are tenable by Matriculated Students, commencing the first, second, third, and fourth year of their course respectively. The Examinations for Junior Scholarships of the second and third years in the Faculty of Medicine take place at the commencement of the second and third year of their medical course. Matriculated Students in Medicine intending to compete for Medical Scholarships of the second year must be of not more than one year's standing as Students of Medicine, and must have attended, in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, two at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the third year must be of two years' standing and not more, and must have attended, in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, four at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the fourth year must be of three years' standing and not more, and must, in addition to the qualifications prescribed above, have attended, in their third year, two at least of the following courses—viz.: Theory and Practice of Medicine, Theory and Practice of Surgery, Midwifery, and Diseases of Women and Children.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are awarded every year.

SIR PATRICK DUN'S HOSPITAL, Dublin (in connexion with the School of Physic).—The payment of £3 3s. to the hospital entitles any student to attend the clinic of the hospital for twelve months, and to attend the lectures delivered by the University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the hospital as perpetual free pupils.

Clinical Lectures are delivered in the hospital theatre at 10 o'clock on Mondays and Tuesdays. In addition to the hospital fee, the payment of a fee of £9 9s. is required for the privilege of attending these lectures. Total fees for hospital and lectures for twelve months, £12 12s.

Sir Patrick Dun's Maternity.—Total fees for college students, £3 3s. Total fees for externs, £6 6s.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance £12 12s.; six months', £8 8s. Summer, three months', £5 5s.

Three resident pupils are selected half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, in Obstetric Medicine, and in Ophthalmic Surgery, will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, and Gynæcology.

The certificates of attendance are recognised by all the universities and licensing bodies in the United Kingdom.

LEDWICH SCHOOL OF SURGERY AND MEDICINE, Peter-street, Dublin (formerly original School of Anatomy, Medicine, and Surgery).—There are endowments in favour of students, subject to conditions prescribed by the founder, in the following departments:—Two in Anatomy and Physiology; two in Minute Anatomy; two in Practical Anatomy; one in Surgery. Certificates of attendance on these lectures are received by the various examining boards; by the Apothecaries' Halls of Dublin and London; by the King and Queen's College of Physicians in Ireland; by the Royal Colleges of Physicians, London and Edinburgh; by the Royal University, the Universities of Dublin, London, and Glasgow; by the Glasgow Faculty of Physicians and Surgeons; and by the Queen's University in Ireland. The Senate of the Royal University having recognised the lectures of this school, arrangements have been made to educate students for its Medical and Surgical Degrees in accordance with its requirements. This school is in a central situation, and is replete with every convenience for study and successful instruction. By its teachers it is connected with nine hospitals, four of which are Medical and Surgical hospitals, one for Fever, one for Midwifery and Diseases of Women and Children, one for Diseases of the Eye and Ear, &c.

Returns for the session 1886-7 have not been received from this school.

CARMICHAEL COLLEGE, Aungier-street, Dublin.—The following scholarships, &c., are awarded to students entering for an *annus medicus* for the current year:—The Carmichael Scholarship, value £15; the Maine Scholarship, value £15; also Lecture Prizes, value £3 and £2 each, £9 being given annually in prizes.

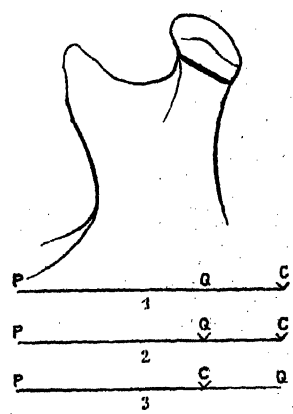
DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 250 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways, and owing to its position affords exceptional advantages for clinical instruction. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Teeth, and those peculiar to Women.

The hospital is visited daily at 8.30 A.M. by the resident surgeon, and at 9 A.M. by the physicians and surgeons. The surgical wards are also visited each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants, who, in addition to their rooms and furniture, are provided with coals and gas.

Fees.—Hospital Practice: Nine months, £12 12s.; six months, £8 8s.; three months, £5 5s. Dresserships: Winter, six months, £21; summer, do., £15 15s.

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital contains 230 beds, 50 beds being specially reserved for patients suffering from fever and other contagious diseases. Two Clinical Lectures will be delivered in each week, in

Clinical Remarks
ON
EXCISION OF THE CONDYLE OF THE LOWER JAW FOR THE RELIEF OF MECHANICAL TRISMUS.



By RICHARD DAVY, M.B., F.R.S.E.,
SURGEON TO THE WESTMINSTER HOSPITAL.

GENTLEMEN,—In 1878 I read a paper before the Association of Surgeons practising Dental Surgery on the subject of excision of the condyle of the lower jaw for trismus. I have now operated on three cases; so will relate briefly the three histories, and then point out why this operation has been performed, and with what results.

CASE 1.—Sarah C——, aged fifty, married, was admitted into Westminster Hospital on Oct. 23rd, 1878, suffering from inability to open her lower jaw by reason of fixity of the temporo-maxillary joint on the left side. In June, 1877, she was much exposed to cold, and for toothache had her left first molar extracted. In August an abscess formed, causing great deformity of her left cheek. In September the abscess burst into her mouth of its own accord, and nearly half a pint of fetid pus was discharged. The abscess cavity slowly healed, but she noticed an increasing difficulty in opening her mouth wide, some thickness of speech, and an occasional spasm of the left angle of the mouth. The trismus has steadily got worse. The patient has been married for twelve years without having been pregnant. She has been treated in St. Thomas's Hospital by a 2 lb. sandbag hung on to her lower jaw, but without any good result. On admission her speech was thick, and she could only pass a pin between her front teeth. The left temporo-maxillary joint was partially fixed; the right was more free. There was no facial deformity, no buccal scar, and no paralysis, but an occasional twitch of the left angle of the mouth. Sensibility was perfect; and she could forcibly contract both masseteric groups of muscles. She ate in a most inconvenient manner, being unable to masticate her food; she was compelled to push small morsels over the molar gums and then swallow them. There was no marked loss of flesh. No clear history of syphilis was given, but she has a small round tubercle by the parting of the frontal hair, and a diffused lump above the left olecranon. The diagnosis was fixity of the left temporo-maxillary joint by reason of condensed tissue around the pterygo-maxillary structures (left), and her twitch was explained by reflex action on the buccal branches of the fifth nerve. On Oct. 28th, 1878, having placed her under the influence of chloroform, by means of a screw and lever I failed to produce any increased motion of her lower jaw laterally or longitudinally. I therefore, on Nov. 5th, excised the left condyle of the lower jaw by an inch cut at right angles to the axis of its neck, nipped the neck across, and removed the condyle with the aid of a pointed lion forceps. Thus the inter-articular fibro-cartilage was left, and no injury done to the internal maxillary artery. There was trifling hæmorrhage; three of my fingers could be admitted simultaneously into the mouth, and she could protrude her tongue between her teeth on awakening. A small sponge was inserted into the wound; this was removed on the following day, and one silver stitch was applied as a compressing agent. She takes sop, and is much pleased at her regained power of eating with comfort. On Nov. 20th the wound had healed; she could speak plainly, and had masticated a quarter of a pound of mutton, after abstaining from solid flesh for eighteen months. On Dec. 8th she was busily assisting her fellow-patients to clear away the breakfast things, when suddenly blood flowed from her mouth and she dropped down dead. The post-mortem showed a large aortic and unsuspected aneurysm of the aorta, which had burst into the œsophagus. I have the skull and lower jaw on the table; and by the side of the lower jaw the condyle and neck removed by the operation I have described.

CASE 2.—Jane J——, aged nine, was admitted into Percy ward on Feb. 4th, 1879, for mechanical trismus, arising from asymmetrical development of the facial bones following scarlet fever. I removed the left condyle of her jaw on February 16th, with the immediate result of being able to open her mouth and insert my fingers. She continued to make good progress, the scar dwindling down to a slight straight line; and she was discharged from hospital on April 16th. She is growing up an interesting, though somewhat timid girl, with marked improvement in her power of speech and increasing facility of mastication.

CASE 3.—H. P——, aged forty-seven, clerk, was admitted into Mark Ward on May 9th, 1885, the subject of left trismus. About 1880 he suffered from toothache on the left side, and his teeth have never been very good. There was no history of syphilis. Fourteen months before admission his lower jaw became fixed; he could open his mouth wide enough to admit a silver fork, but no food on it. He applied for relief at Guy's Hospital and remained in for two months, but did not improve. He was recommended to come to Westminster Hospital by his employers. On admission his case was clearly one of unilateral trismus, and seemed to depend on some fixity below the zygoma and around the anterior aspect of the coronoid process of the lower jaw. Physical examination of the mouth was impossible. His breath was fetid, teeth numerous, and speech thick. He had lost flesh. As he had submitted to a most varied surgical discipline without any good result, I proposed excision of the condyle of the jaw on the left side. He readily consented, and as a preparatory measure I had his face shaved. Great was his surprise (for he had not been

shaven for sixteen years) to find immediately beneath his left malar bone a deep depressed cicatrix, of which previously he had no cognisance. On May 12th the operation was performed in the usual manner, and the condyle and part of the neck removed, also the attachment of the pterygoideus externus muscle. No difficulty was experienced, and there was no bleeding. The immediate result was that the mouth could be opened, and three fingers inserted. He was ordered as a gargle four drachms of chlorate of potash and three drachms of compound tincture of lavender, in a pint of water; and as a tonic, twenty minims of tincture of perchloride of iron, in water, three times a day. The man made an uninterrupted recovery, and left the hospital on May 30th, well able to eat and speak. The cicatrix is now being hidden by regrowth of his whiskers. On July 31st the patient was able to report good progress, the interval between the teeth being at the widest point three-quarters of an inch. On August 17th, 1886, I carefully examined him. When he opened his mouth there was found to be three-quarters of an inch between the incisors. He was free from annoyance. There was no fetor of breath, and no thickness of speech. The cicatrix was completely hidden by whiskers, and so also was the submalar one, about which we know nothing. He was able to eat half a pound of mutton for dinner, was gaining flesh, and had his old sense of well-being.

Why the operation has been performed.—A very few words will explain how miserable is the condition of a patient unable to eat or speak with comfort; how troublesome it is

to suffer from oral and dental fetor; how alarming to watch the gradual loss of flesh and healthful vivacity. Patients will direct the surgeon as to which of the two hinges of the jaw is at fault, and in all cases make a careful and minute examination of the facial skin and buccal mucous membrane. By the aid of this diagram (see engraving, *ante*) you will notice the line marking the spot for the excision of the condyle and neck of the jaw, and also the three succeeding lines showing the varying conditions of jaw leverage. In each instance, for the act of opening the jaw, let C be the fulcrum, P the power, and Q the weight. No. 1, the position of power and weight in any normal jaw. No. 2 (lever of the second order), the position of two fulcra in these conditions of unilateral trismus. No. 3, the position of power and weight, after the operation of removal of the condyle; or, in other language, the conversion of a normal mechanism of the jaw (lever of the second order) into that of an operated case (lever of the first order). Compare Nos. 1 and 3. And now look at No 2, which, in my opinion, explains the secret of many of these unilateral trismus cases, and also at this rough model I have cut out of wood, showing the condyle of the jaw, the mouth, and the temporo-malar coronoid structures. From dental irritation, or an old abscess, or other accident, a local definite adhesion results between the coronoid process and zygomatic fossa; or between or around the plane of the pterygo-maxillary ligament, fixing the lower to the upper jaw at any point between the teeth anteriorly and the temporo-maxillary joint posteriorly. It is obvious that any attempt to depress the symphysis is negatived by the new material (disease) acting as a fulcrum (instead of a movable mass); and as the condyle naturally is the fulcrum, there are two fulcra, and until one is knocked away (the condyle) no opening of the mouth can take place.

With what results this operation has been attended.—Professor Humphry's case (in 1855) of excision of the right condyle of the lower jaw for chronic rheumatic arthritis was successful; and in a letter sent to me in November, 1878, the Professor says: "The patient was well and able to masticate comfortably some years afterwards; the operation answered the purpose well." My three cases have also mechanically succeeded. Two are alive and well; the first died of syphilitic aneurysm of the aorta immediately after enjoying a good breakfast. I show you also to-day a specimen of chronic rheumatic arthritis of the temporo-maxillary joint (left side). This specimen came from our class subject in operative surgery (session 1884); for accidentally one of my pupils, in operating for the excision of the condyle of the inferior maxilla (an operation then taught by me as a recognised operation) came across genuine disease, and secured this not common preparation. We have on the table specimens of Case 1, superior and inferior maxillæ, condyle, and resultant cicatrix; Case 2, left condyle removed; Case 3, left condyle removed; operative specimen of arthritis of the temporo-maxillary joint. Strangely enough, all my preparations are left side specimens.

One word on the *method of operating*. Take the tragus of the ear as your guide, and make a horizontal incision (not more than an inch) across and down to the neck of the jaw, so as to allow cutting strong forceps to embrace the neck; divide the neck and evulse the condyle. This act of turning out the head of the bone may be done by the bone nippers or pointed strong bone forceps. I am tempted, while on this point of turning out heads of bone, to draw your attention to a valuable plan of impacting a strong steel lever into the cylindrical substance of the bone itself; this impaction not only gives a useful leverage in turning out small pieces of bone in cramped corners, but also allows the free play of the knife around and close to the bone, without the blades of any bone forceps coming in the way of sight or blunting the edge of the knife on the blades of the forceps. The leaving of the inter-articular fibro-cartilage prevents any future bony union occurring. Coupling, then, these three cases of my own with Professor Humphry's case, I am inclined to recommend the operation of excision of the condyle of the jaw for mechanical trismus. Instead of misery and inanition, by recourse to an easy and not dangerous operation the surgeon restores freedom of speech and reopens the gateway of alimentation; no large scar results, and in adult males this scar is hidden by hair. This operation affords another example of the warrantable sacrifice of perfectly healthy parts in one locality so as to effect the well-being and happiness of the whole body.

THE PATHOLOGY OF PUERPERAL ALBUMINURIA.[1]

BY ROBERT MAGUIRE, M.D. LOND., M.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, AND JOINT LECTURER ON PATHOLOGY, ST. MARY'S HOSPITAL.

THE cases of puerperal albuminuria complicated with retinitis are of great importance, as presenting a feature which links the affection, in one of its forms, more closely to albuminuria the result of organic kidney mischief; and I should be glad if the ophthalmologists could tell us whether the occurrence of retinitis in puerperal cases has any influence on the prognosis of the albuminuria. The common form of puerperal albuminuria is characterised by the fact that in the later stages of pregnancy a large quantity of albumen appears in the urine, which, after delivery, disappears in a marvellously short space of time, and the patient then resumes her usual health. Such is a common course. But sometimes the termination is more serious: uræmia in its various forms may appear during the pregnancy and labour, or after delivery the albumen may still continue to appear in the urine, and the case may lapse into one of chronic Bright's disease. It is evident, then, that in the more serious form we have to do with an organic kidney lesion. This lesion was for long considered to be a venous hyperæmia from pressure; but, as a matter of fact, this has seldom been found, and, moreover, the urine of these cases is not in all respects the same as that met with in venous hyperæmia. A lesion more commonly found is the very opposite to this—that is, anæmia of the kidney with fatty degeneration, believed to be due to reflex spasm of the renal arteries, although obviously for this view there is no sufficient basis. But knowing that such a lesion is found, let us consider the more favourable cases, and inquire, how can it be that an extensive fatty degeneration of the kidney, and, what is more, a *chronic* fatty degeneration, should clear up in so short a time after delivery and leave no trace behind? *A priori*, this seems hardly possible. Such a consideration, too, brings into one's mind those cases of functional or cyclic albuminuria which are now occupying so largely the attention of physicians, and one cannot help asking whether also, in the less grave form of puerperal albuminuria we have to deal with a merely functional derangement. In this connexion I may be permitted to refer to some observations upon which I am engaged, and which, although not yet completed, have already yielded curious results. I will not go into details, for I purpose publishing the results later on in a more complete form.[2]

The precipitate obtained by the action of nitric acid or heat upon an albuminous urine is not one simple albuminous body, but is composed of serum-albumen—possibly in several varieties, only distinguishable by their *physical* properties,—and, in addition, a substance *chemically* different from serum-albumen—that is, globulin. This may be separated from the serum-albumen by saturating the neutralised urine with sulphate of magnesium in the cold; the globulin is precipitated in a soluble (non-coagulated) form, and the serum-albumen remains in solution. I am engaged in trying to determine what is the proportion of globulin to serum-albumen in albuminous urines, and whether this ratio varies in the different varieties of kidney disease, and in the different stages and phases of the same disease. Such a research seemed likely to throw light on the intimate pathology of albuminuria, and I specially hoped to find by this means a chemical diagnosis between albumen due to organic kidney disease, and that occurring, usually in cyclic rhythm, without kidney disease. My observations are as yet too limited in number to permit me any generalisation, but their results are certainly suggestive.

In four observations upon the urine of a case which presents all the most characteristic phenomena of functional albuminuria, I have found that the precipitate with nitric acid or heat is composed entirely of globulin, not a trace, or only the very faintest trace, of serum-albumen being present. This determination may be contrasted with that of a case of

[1] Being the basis of remarks made during a discussion on a case of Albuminuric Retinitis occurring in Pregnancy at the Harveian Society of London.

[2] See also THE LANCET, June 5th.

granular kidney, where, of the total amount of albumens, 70 per cent. was serum-albumen and 30 per cent. globulin; it may also be contrasted with that of a case of extreme general anæmia, and probably fatty degeneration of the kidney, in which, of the total amount of albumens, 30 per cent. was serum-albumen and 70 per cent. globulin. These figures are only approximations, but they will serve the present purpose equally well, with the decimals in which the determinations were worked out. In connexion with the latter case it may be mentioned that, if one may trust the clinical features, the disease was at first functional and afterwards became organic; and it will also be observed that, if the diagnosis be correct, there is here a kidney lesion, similar to that found, in one variety at least, of puerperal albuminuria.

Now, to come more directly to the point in discussion, I have examined the urine of one case of puerperal albuminuria in which the pregnancy and labour had terminated without mishap, and in which the urine, although still containing a large amount of albumen, was rapidly becoming normal. Here I found, as in the case of functional albuminuria already described, that there was an entire absence of serum-albumen and a precipitate with nitric acid and heat, which was composed entirely of globulin. Thus, if my observations be correct, and I of course admit that they must be multiplied before making any generalisation, this form, of puerperal albuminuria, which cures itself, is chemically allied to functional or cyclic albuminuria, and a strong suggestion arises that, as in the latter, so in the former, we have no organic kidney mischief. It is, from a practical point of view, highly desirable to diagnose during the progress of a pregnancy the one form associated with organic change, which will probably not recover, from the other form, in which, from what appears above, there is probably no organic change, and which will recover. Retinitis is a complication, which under other circumstances is generally found in connexion with organic change in the kidneys and serious symptoms. It is important, then, to ask if, when it occurs in puerperal albuminuria, it has the same grave significance; if the cases of puerperal albuminuria associated with retinitis invariably continue after delivery as cases of chronic Bright's disease; and if, finally, we may call this complication to our aid, possibly together with the chemical phenomena I have mentioned, in determining the prognosis of a given case. To summarise the above remarks, there is undoubtedly a form of puerperal albuminuria which is associated with an organic lesion of the kidney, and which we may call nephrogenic; but there is also another form, in which there is probably no such kidney lesion, which is probably due, as I believe, to the profound blood change of pregnancy, and which may hence be styled hæmatogenic.

Westbourne-terrace, W.

THE RATIONAL METHOD OF TREATING CATARACT PATIENTS, TO THE EXCLUSION OF COMPRESSES, BANDAGES, AND DARK ROOMS.

BY SIMEON SNELL,

OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY AND TO THE INSTITUTION FOR THE BLIND; LECTURER ON OPHTHALMIC SURGERY AT THE SHEFFIELD SCHOOL OF MEDICINE.

THE title of this paper is similar to that of an article in the June number of the *American Journal of Ophthalmology* by Dr. Julian J. Chisolm, of Baltimore, and it is so expressive that I have adopted it.

The method proposed by Dr. Chisolm[1] is at variance with prevailing ideas, and marks, I believe, a revolution in our mode of treating cataract, and I would add many other cases. He asserts that all our efforts at extreme exclusion of light are both undesirable and unnecessary. The eyelid is the natural splint to the eye, and the globe covered with this allows about the same amount of light to pass into the eye as was the case before the cataract was extracted. He alludes, moreover, to the fact that while on the operating table, after removal of the opaque lens, and with a strong light on the face, there is no blinking or other evidence of suffering inconvenience from it. Further, he contends that the warm coverings over the eye and the great seclusion from light so often adopted are prime factors in the causation of the photophobia and lacrymation witnessed after cataract extraction, and in this way a means of prolonging convalescence. I have long felt this myself, and have therefore always been desirous of lessening the covering as speedily as possible. The method Dr. Chisolm advocates is to seal the eyelids with fine isinglass plaster in the manner to be mentioned presently. He records very excellent results in the sixteen cases of cataract extraction for which he had employed it; and he claims that there is less restriction for the patient with his method as to lying quiet on his back, the patient being allowed to sit up to his meals and to rise from bed when necessary, and that, as the eye is free from irritability, any covering is more quickly removed, convalescence is much more rapid, and the stay in hospital is shorter.

I am free to confess that I have seldom seen a paper that more directly appealed to me as to the justice and reasonableness of the conclusions set forth. The journal with the article in question reached me about the middle of July, and I immediately determined to adopt in practice the plan Chisolm advocated. I speak later on of the cases which have been so treated, but here I may say that the conclusion at which I have arrived from the results of those cases is such that I expect I shall be able to endorse Chisolm's words: "The revolution in the after-treatment of cataract and iridectomy patients in this hospital is complete. From this time hence, all bandages, compresses, and dark rooms will be among the things of the past, to be remembered only for the discomfort they occasioned." That is my present, and, I believe, will be my future, experience. The list of operations in which the method is applicable may, moreover, be extended, and it is useful in injuries of the conjunctiva, cornea, or sclerotic—in fact, in all wounds, operative or accidental, except those in which the discharge is likely to be free, and which would probably require a frequent change of plaster.

Passing to the operations in which I have employed it, I find a total of eighteen cases in hospital and private practice.[2] Twelve of these were operations on the crystalline lens, seven being extractions of senile cataracts, two traumatic cataracts, two removal of dislocated lenses, and one needling a soft cataract in a child. The extractions were as follow, and I take the first case as a typical one, and give it more in detail.

CASE 1.—Mrs. S——, aged sixty, a patient in the Sheffield General Infirmary, was operated upon on July 27th last. The cataract (left) was extracted by a shallow lower flap; a small iridectomy was performed, and there were no accidents attending the operation, which was done, as my practice is, in the ward, with the patient lying in her own bed. A 2 per cent. solution of cocaine, with salicylic acid, had previously been instilled. Both eyes were next sealed up with isinglass plaster in the manner to be presently referred to. The ward was not darkened, and a screen was placed round the bed more for the protection from currents of air than anything else. She made no complaint of the light. The next day everything was well; a very little secretion had exuded from the eyelids and become fixed in the plaster. She had been allowed more liberty as to moving about than is usually accorded to such patients. On the third day the eye looked well, and there was no complaint made. When the plaster was removed the patient immediately opened the eye, and bore light well; the wound had healed, and the eye was looking in every way satisfactory. The plaster was reapplied. On the fifth day the plaster was removed and a shade used over both eyes; the patient was allowed to get up. On the seventh day the patient was walking about the ward, and found no discomfort from the light. She was as well as most cases are between the second and third week. On the tenth day (August 6th) she left the infirmary, walking home unaided. In the other eye there was an incomplete cataract, and the sight was very indifferent.

CASE 2.—Male, aged sixty-one. Aug. 2nd: Extraction of old traumatic cataract.—6th: Shade used.—18th: Made out-patient.

CASE 3.—Female, aged seventy-three. Aug. 4th: Right

[1] Vide also THE LANCET, vol. ii. 1886, p. 296.

[2] Since the above was written, in ten additional cases my experience has been equally gratifying.

eye operated on. 6th: Plaster reapplied. 9th: Shade used. 18th: Left the infirmary.

CASE 4.—Male, aged sixty-six. August 9th: Right eye operated on. 12th: Plaster renewed. 14th: Shade used. On this day he was found up and eating his dinner with the shade pushed up.

CASE 5.—Male, aged sixty-three. August 16th: Right eye operated on.

CASE 6.—Male, aged forty-eight. August 16th: Right eye operated on.

CASE 7.—Male, aged sixty-three. August 16th: Left eye operated on.

In each of the above cases a shallow flap was formed; in some an iridectomy was performed, and in others not.

CASE 8.—Male, aged fifty-seven. July 23rd: Lens dislocated forwards; extraction below; shallow corneal flap. This case did well.

CASE 9.—Male, aged sixty-five. July 26th: Lens dislocated forwards. 29th: Shade used. August 9th: Made an out-patient.

The traumatic cataract cases were the following:—

CASE 10.—Male, aged twenty-six. July 19th: Cataract extracted through a small corneal wound. 21st: Shade allowed. 22nd: Made out-patient.

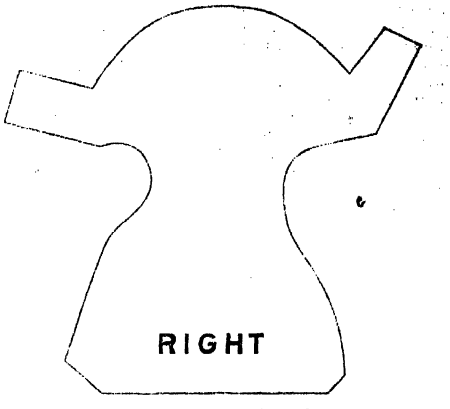
CASE 11.—Male, aged twenty. Aug. 2nd: Operation same as last. 4th: Shade used. 5th: Left the infirmary.

CASE 12.—A child. Lens needled on Aug. 16th.

CASES 13, 14, and 15.—Iridectomies; two being marginal ones in cases of zonular cataract.

CASE 16.—An iridectomy in a case after cataract extraction, with closed pupil.

CASE 17.—Needling opaque capsule after cataract operation.



CASE 18.—Sclerotomy in a man aged about forty.

Chisolm gives the following directions as to applying the plaster. "The lid of each eye was kept closed by a piece of isinglass plaster, 2½ in. long by 1½ in. wide. The piece of plaster, made thoroughly pliant by being soaked in water, was spread over the lids from brow to cheek, and carefully adjusted by stroking it with the rubber spoon used for pressing out the lens. In a very few minutes this piece of diaphonous silk plaster was dry, and the patient was ready to walk from the operating table to his bed in the fourth storey of the hospital." He elsewhere speaks of the piece of plaster being large enough to extend from cheek to brow and from one canthus to the other.

At first I adhered to these directions, but I was led soon to vary somewhat the plan. Thus I found it undesirable, and indeed unnecessary, to place the plaster over the eyebrow, and the next step was to cut the upper edge of the plaster to the curve of the orbital margin; and the advantage suggested itself of leaving a portion on either side to project at each orbital angle. The piece on the inner side was thus obliquely upwards, and the outer one was horizontal, for fixing it to the malar bone. Then, instead of reaching from canthus to canthus, it soon appeared advisable to constrict the plaster at the point where it passed over the margins of the lids and to leave a small space at either side for drainage, and the one on the inner side for the instillation of atropine or eserine drops. The shape of the plaster may be cut for each eye, but I have had a form made in metal which indicates probably the one generally required. Any particular alteration an eye needs is easily made. The annexed woodcut indicates the shape of the plaster, the silk side being uppermost. I have had the forms cut in the metal solid, as the drawing represents, and also as a hole in a plate of metal corresponding to the shape given. This latter is perhaps more useful, as it keeps the plaster flat at the time the shape is marked out on it.

The kind of plaster is of great moment. I have experimented with several kinds of silk, muslin, cambric, gauze, &c., and the form now used is the best yet arrived at, and, indeed, answers our purpose admirably. It is silk salicylated isinglass plaster (Seabury and Johnson's). It is quite transparent; put on a book it is very easy to read printing through it. It quickly dries, readily adheres, is easily fixed in its situation, and does not tend to curl up, which is often a characteristic of such plasters. The plaster, before being applied, may with advantage be a little snipped at several places along its edge to enable it to fit more accurately, and whilst it is drying it is often advantageous to push the cheek upwards to prevent displacement by facial muscular movements. In cataract cases it is essential to seal up both eyes, and this is generally true of other cases, but occasionally I have only closed one eye and often allow the sound organ liberty before the other is permitted it. It would appear that formerly in some hands plaster was used for closing the eyes after cataract operations, but I believe in a much less complete manner than Chisolm has advocated, and the routine practice, with perhaps every operator, has long been the use of bandages and pads, which his plan numbers among the things of the past. Such a method would hardly have been feasible in the pre-cocaine days. My experience of the plan is particularly gratifying, and is, moreover, pleasing alike to my assistant and the nurses.

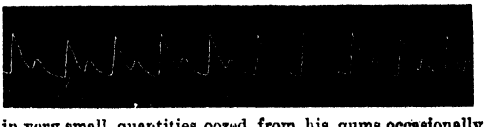
In conclusion, the advantages, particularly in cataract cases, of the plan Chisolm advocates over the routine method by bandages may be summed up under the following heads:—1. More comfortable to the patient, and less dread

of injury by movements. 2. Less discomfort to nurse and friends, or, in hospital, to other inmates of the ward, from less darkening of rooms. 3. Less liability to disturbance, and thus more freedom in movements permitted to patient. 4. More evenly and exactly fitting. 5. And thus allowing a more correct coaptation of wound, and, it is believed, experience will prove a more ready healing. 6. Inspection of eye is allowed without disturbance, for in this way swelling of lids or discharge are readily seen. 7. Affords a ready means of using eserine or atropine without disturbance of eye, and allows of drainage of tears, &c. 8. Absence of photophobia and lachrymation; when eye is opened, a ready examination in good light is allowed, patient being able to open eye fully. 9. Less confinement to bed, a quicker convalescence, and shorter stay in hospital.

Sheffield.

CLINICAL NOTES ON HÆMOPHILIA.

BY THOMAS OLIVER, M.D., M.R.C.P LOND.,



PHYSICIAN TO THE INFIRMARY, NEWCASTLE-UPON-TYNE; AND LECTURER ON PRACTICAL PHYSIOLOGY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

THE following cases of this interesting affection have lately come under my notice.

J. P——, aged thirty-three years, single, a groom, was admitted into the Newcastle Infirmary, complaining of bleeding from the mouth and of passing very dark-coloured urine. He told us that neither of his parents was a bleeder. An unmarried maternal uncle, however, used to bleed a great deal from the nose, and ultimately died after a vomiting of blood. A married sister of the patient has a tendency to bleed; and one of her sons, aged eight has frequently spontaneous hæmorrhages, which are with great difficulty controlled. The personal history of our patient is interesting. When but an infant in the cradle, a leech for some reason or other was applied to his side, and on that occasion, he has been told by his mother, the bleeding was with difficulty stopped. At the age of nine he was accidentally cut on the outer side of his right eye; this bled for several weeks. When he was fourteen he had a tooth extracted, and for a

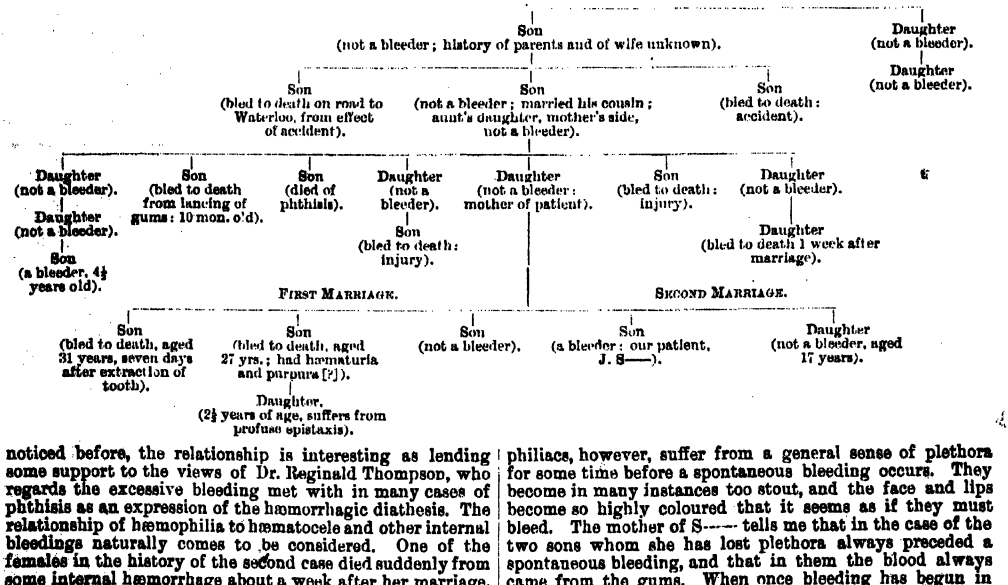
week he had the cavity plugged; as this failed to check the hæmorrhage, a cork was fitted into the cavity, and the upper teeth were kept firmly clenched upon it for two or three weeks. Two years later he was cut between the right thumb and index finger, and for a month the bleeding continued more or less. At the age of nineteen he was wounded on the head, and for fourteen days he attended as an out-patient at the infirmary before the bleeding was stopped. About this time, too, he received a small wound, not much larger than a scratch, on the right arm, which bled for several days each time the dressings were changed. He has frequently had epistaxis, and it has always been with difficulty that the bleeding has been arrested. When he was twenty he passed blood in his urine, and again at the age of thirty; also at the beginning of the present attack. Each bleeding from the kidneys lasted for about a week. There was no bleeding during the first or second dentition. He states that a sharp tap on the skin is frequently followed by ecchymosis; that a strong blow causes a large swelling, particularly if the arms, calves, outer side, and back of thighs are made the seat of it. His joints, when moved sharply and suddenly, have frequently swelled and been painful, especially the knees and elbows. The swelling will last for a fortnight, and the veins over it are seen to be distended. Beyond having had small-pox and gonorrhœa within the last few years, there is nothing calling for notice until the beginning of the present attack. Three weeks before his admission the patient had been treated for pain in his right side. The medicine taken made his gums sore and swollen. On Sunday, May 24th, he awoke at 5 A.M. with his mouth full of blood. The blood oozed from his gums. That evening he had hæmaturia, which lasted until May 28th, and on this point I would remark that within three days of the disappearance of blood from the urine that fluid failed to exhibit the least trace of albumen. On May 26th the urine was port-wine-coloured, muddy, had a dark brown deposit, was faintly acid, sp. gr. 1018, contained a large quantity of albumen, and, microscopically, a large number of free blood-cells; pulse 80. In spite of rest in bed, and medicinal treatment by iron, ergot, hamamelis, &c., blood still oozed from the gums, though in diminished quantity. The gums remained swollen, pale, and ragged at their junction with the teeth. Beyond a slight rounding of the features and pallor of face, the patient presented nothing remarkable. His heart and lungs seemed healthy. On June 16th, feeling quite well, but with a tendency for blood still to ooze now and again from the gums, he left the hospital, only to be readmitted a few weeks later for a painful swelling of the knee-joints and bleeding from the gums. Fluctuation in the joints was well marked; movement of them was painful. When the swelling subsided, he left the hospital, cautioned as to the extreme necessity of taking care of himself. Six or seven weeks after this he was in a public-house with some friends. Two of the men began to quarrel, and just as words were about to be replaced by blows, our patient, while acting the part of mediator, was thrown violently against the side of the door. He went almost immediately to the infirmary, on entering through the porch of which he made some jocular remark as to the injury he had received. He was examined by one of the house-surgeons, who, unfortunately not knowing anything of his antecedents, did not detain him. To this official he complained of pain in the right side of the chest at the seventh rib, increased on forced inspiration, and slightly, too, on pressure. There was tenderness over the right pectoral region. His face was pale, but the lips were well coloured. Respiration was short and rather hurried; pulse 64. No fractured rib was detected. Expansion of chest appeared equal on both sides. The chest was carefully examined by those present: no dulness was detected either in front or behind; breath sounds were normal over the whole chest, save over each base posteriorly, where friction was heard, and also slight crepitus at the end of inspiration. As nothing else was observed, the case was regarded as one of bruise of the thoracic walls caused by a fall. A flannel bandage was applied firmly to the chest, and the patient was sent home, being told to lie in bed for a day or two. On the following day the man died unexpectedly. By order of the coroner a post-mortem examination was made about twenty-four hours afterwards by our house-physician, Mr. Waldy, to whom I am indebted for the report: "Rigor mortis not present; skin and mucous membranes very blanched; no external bruises or marks of any kind. On the right side of the chest, over the manubrium sterni and the three upper costal cartilages, was a distinct bulging, in which no fluctuation could be felt. Reflecting the skin, the great pectoral muscle on the right side was found distended with dark fluid blood. On cutting through the costal cartilages the same dark fluid blood flowed out of the chest. The anterior mediastinum was filled with the same material. From these sources a large basinful of fluid was removed. The right pleural cavity contained about two pints of similar dark-coloured fluid, and in addition several large clots about the size of the closed hand. The left pleural cavity contained a small quantity of dark fluid and blood clot. Both pleuræ were here and there adherent to the chest wall. No ruptured vessel could be detected, and no evidence of disease was found. It is possible that some pleural adhesion may have been torn."

Scarcely had this patient passed out of sight than the following case was seen by me. J. S——, aged eighteen, an apprentice fitter in an iron foundry, a pale, sallow-looking lad, with rather a prominent brow and shape of head suggestive of previous hydrocephalus, went to the infirmary at midday complaining of toothache, and had the aching member extracted. It bled freely until 6 P.M., when he returned to the infirmary and was admitted. For forty-eight hours the bleeding continued, and that rather profusely. After that it ceased, but only temporarily, for every now and again hæmorrhage would start spontaneously from the socket. Strange, too, this bleeding generally came on at night. A few days after the extraction of the tooth the patient was so exhausted by the bleeding that he could scarcely stand. Five weeks after this he came to my out-patient department. He did not look even then as if he had recovered, nor for many weeks after. He told me that he never suffered from bleeding in his infancy. Ten years ago he was cut on the left thumb; this bled for a fortnight, and was followed by great exhaustion. With that exception he never had any severe bleeding until the extraction of the tooth. For six months prior to this, however, he had noticed that blood

in very small quantities oozed from his gums occasionally below the lower incisors. He has never spat or vomited blood, nor has he suffered from hæmaturia. The patient had two half-brothers, who bled to death; and he tells me that when they got a severe knock—and this applies also to himself—nothing would be noticed for a day or two, and then they would be laid up with "a swelling and colouring of the flesh." His joints have never swelled, nor have they been painful. So far as his chest is concerned, the respiratory murmur is healthy. The second sound of the heart is reduplicated over the apex and base, and the pulmonic is more accentuated, comparatively speaking, than the aortic. With these exceptions the sounds of the heart call for no remark. The pupils are dilated and respond to light. The pulse is 84, soft. A sphygmographic tracing shows low tension and large dicrotic wave, and bears a close resemblance to many tracings of ordinary anæmia. (See diagram.) When he had made a fair recovery he returned to work. He was only thus engaged a few weeks when he was struck on the right thigh by an iron wheel. The skin fortunately was not broken. The blow, though not severe, was followed by rapid swelling of the thigh, stiffness of the muscles, extreme pain on movement, and great discolouration of the skin. The effects of the injury were such that he was obliged to take to bed, and it was nearly a month before the swelling disappeared.

Hæmophilia is, as a rule, never detected until there is an injury. There is nothing which distinguishes the subjects of this affection from healthy people so far as outward appearances are concerned. It is true that in many a certain pallor of countenance, thinness of skin, light-blueness of eyes, and fairness of hair have been present; but these are far from being distinctive; besides the pallor is, in most of them, only noticed after a bleeding. In both of these cases the muscular system was well developed. One exhibited a marked tendency to swelling of the joints. Both suffered from ecchymosis and swelling of the skin after blows. I have not noticed in either of them a more diffused than normal impulse of the heart—a point to which Grandidier

drew attention. In one of the cases the second sound of the heart was strongly reduplicated; and the pulse, judged of by the sphygmographic tracing, shows low arterial tension. The spontaneous hæmorrhages generally came on at night—always from mucous membranes, save in the first case, in which there was occasionally hæmataria. Only in the first case could it be said that there existed prodromata, and when present the hæmorrhage which followed was severe, and frequently from the kidney. The blood seemed in every instance simply to ooze out of the gums, and while no bleeding points could be seen, the actual amount of blood lost in a few hours was considerable. Whatever was done, the blood kept trickling, becoming paler the longer it flowed, and exhibiting less and less a tendency to clot. I do not know whether my first patient had taken blue pill or not. The medicine supplied to him before his admission into the infirmary caused his gums to be sore. Dr. Wickham Legg states in his monograph, on the authority of Burnes, that the taking of blue pill has been followed in these subjects by profuse hæmorrhage from the gums and nose, and that these symptoms recurred again and again when the blue pill was repeated. The patient himself attributed the bleeding from the gums on this occasion to the medicine he had taken.



On looking over the family history of the second case, it will be noticed that one of the members died of phthisis. The association of the two diseases here is slight, but as the occurrence of phthisis in the family of bleeders has been noticed before, the relationship is interesting as lending some support to the views of Dr. Reginald Thompson, who regards the excessive bleeding met with in many cases of phthisis as an expression of the hæmorrhagic diathesis. The relationship of hæmophilia to hæmatocele and other internal bleedings naturally comes to be considered. One of the females in the history of the second case died suddenly from some internal hæmorrhage about a week after her marriage. She was well two hours before death. As there was no external hæmorrhage, ruptured hymen could not have been the cause; and in the absence of post-mortem evidence such causes as bleeding from a ruptured ovary or ulceration of mucous membrane with or without perforation can at the best only be but conjectural.

The hæmorrhagic diathesis is more the inheritance of males than females. Both of the cases here reported are males. When women suffer, they appear to do so less intensely, although by some, it is said, that in them menstruation is profuse, and that at the climacteric period there is excess of hæmorrhage. Where these conditions are present, I should regard them as in all probability dependent upon a local cause. The sister of J. S—— menstruates normally, and is strong and healthy-looking; and as for his mother, she has, neither at her menstruation, parturition, nor at the climacteric period, lost more blood than the average. (See genealogical schema.) One cannot scan the schema of the family history of S—— without being struck by the remarkable influence of heredity in the development of hæmophilia, and by the striking manner in which the disease has skipped the females, only to appear in the most marked form in the sons, and to lead in them to a fatal issue on the slightest provocation. The potency of transmission by the female—she herself exhibiting no symptom of the affection—is shown in a remarkable manner in the mother of S——, who has been twice married. Two of three sons by her first marriage have died from the effects of bleeding, and of the son and daughter by the second marriage, the son has already been the subject of dangerous bleeding. The resemblance in this to the hereditary transmission of gout receives support from my case. So far as any connexion with scrofula is concerned, I see no indication unless the prominent forehead, the somewhat hydrocephalic shape of the skull generally, and the pallor and fineness of the skin of S—— may be taken as pointing in that direction. It is believed that hæmophilia is much more frequently met with in Germany than elsewhere, and as close intermarriage with relatives is there so little discouraged, it has been thought by Rieken that the marriage of cousins has something to do with its development. Two generations back, and in the lineal descent of J. S——, we meet with the marriage of first cousins; but while neither of these was a bleeder, it will be observed that two of the brothers on the male side died from hæmorrhage. The marriage of first cousins in this instance, however, had nothing whatever to do with the development of the disease.

In my first case the only prodromon noticed was pain in the back, and this always preceded hæmaturia. Most hæmophiliacs, however, suffer from a general sense of plethora for some time before a spontaneous bleeding occurs. They become in many instances too stout, and the face and lips become so highly coloured that it seems as if they must bleed. The mother of S—— tells me that in the case of the two sons whom she has lost plethora always preceded a spontaneous bleeding, and that in them the blood always came from the gums. When once bleeding has begun in these cases, not only is it difficult to check it, but when checked it is apt to come from other sources. In the case of the eldest son of Mrs. S——, whose death was due to hæmorrhage after the extraction of a tooth, no sooner was the bleeding stopped in the mouth than the most profuse epistaxis occurred, death supervening in his case on the seventh day. Profound exhaustion follows each bleeding. The urine in each of my cases, excluding the period of hæmaturia in P——, was normal. In the case of S—— the urine, examined several weeks after the last hæmorrhage, showed a diminution in the amount of urea eliminated daily. There was on an average only 218·5 grains eliminated daily—less than half the normal. A similar diminution was noticed by Grandidier, and is alluded to by Wickham Legg.

The second patient complained that his vision was imperfect. I sent him to Mr. Williamson, ophthalmic surgeon to our infirmary, for examination, who favoured me with the following report:—"Refraction myopic; both discs slightly swollen with large veins, crescent commencing at edge of each; choroid thinned from stretching; yellow spot seen in right eye with unusual distinctness. These

GENEALOGICAL SCHEMA (FAMILY OF S——).

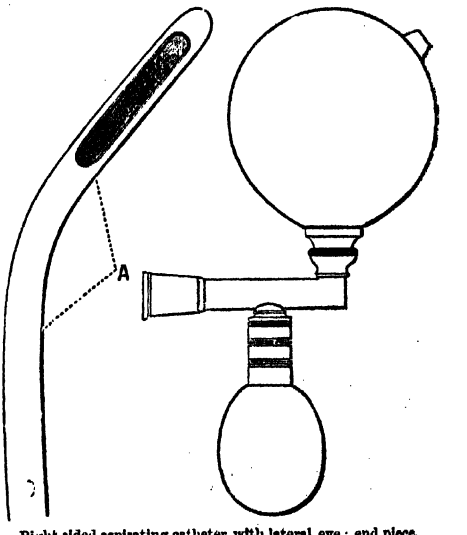
appearances are all accounted for by the gradual stretching and straining of a myopic eye."

I am inclined to regard cases of uncontrollable hæmorrhage from the cord in newly born children as instances of hæmophilia. It is true that in most of these cases one may fail to obtain a history of heredity; but is heredity, after all, absolutely required to constitute the disease? In most cases it is present, and forms a valuable point in the diagnosis, but whether really essential is another thing. Take the following case, which happened in the practice of a medical friend a few months ago:—A child is born at full time; it is plump, healthy-looking, and cries lustily. The cord is carefully tied and separated, and the child is given to the nurse. Before leaving the room the doctor has his attention drawn to the fact that the child is bleeding at the umbilicus. The cord is carefully examined, but exhibits nothing unusual. An additional ligature is placed around it and firmly secured. A few hours after this the nurse examines the child, and, finding its under-garments soaked with blood, the doctor is again sent for. Additional ligatures and hæmostatics are applied, but they are as nothing. The child dies from bleeding by the cord, unable to be checked. If the disease here is not hæmophilia, it must be something closely akin to it.

So far as the pathology of the disease is concerned, I believe the state of the blood and bloodvessels and a defective control action on the part of the vaso-motor centres are the important factors in its causation. When the bleeding first commences there is a slight attempt at clotting, but it is never complete, and the longer the blood trickles the paler and more watery it becomes. To the plausible theory of Resal, that the subjects of hæmophilia possess an increased power of making blood, and that in them hæmorrhages occur amongst those capillaries which are thinnest, I cannot subscribe. My experience is that while plethora precedes the spontaneous hæmorrhages, hæmophiliacs recover extremely slowly from them. Such people feel exhausted for weeks it may be, and their pallor is long maintained. It seems to me that they have best health when pale. That a blood condition acts in some way or another as a cause we must admit, judging from the effects produced in other diseases where the blood is altered. In purpura and scurvy hæmorrhages are frequent; in some forms of anæmia and in certain diseases of the spleen a tendency to bleed is frequently noticed. I have known internal hæmorrhage in leukæmia prove fatal, and in a case of mitral stenosis and regurgitation in an anæmic young lady I have seen the incision of a gumboil followed by an alarmingly persistent hæmorrhage; the oozing lasting for days, in spite of plugging and strapping the jaws. In these cases of uncontrollable hæmorrhage, in which there is no hereditary history of bleeding, I am inclined to think that we have the thin-walled condition of the bloodvessels and the watery state of the blood met with in hæmophilia, and that it only requires the other factor, an inactive vaso-motor centre, to complete it.[1] In favour of the blood condition as a cause I would submit this, since I have noticed it again and again: Once the blood has undergone the marked alterations met with in leukæmia, it will be found that injuries which had been received years before the illness began bled but normally, and were easily restrained; but that slighter injuries received during the illness are followed by hæmorrhages slightly excessive and difficult to check. The healthy stimulus to the vaso-motor centre is healthy blood; alter the blood, and you either have its function increased, as in Bright's disease, or lowered, as, I believe, in hæmophilia. Everybody regards hæmophilia as most distinctly hereditary, and what does that mean? I take it to mean that during intra-uterine life the development of the cardio-vascular system is in some way or other interfered with, owing to the transmission of some ancestral peculiarity, the result of which is that not only is the blood itself altered and the tubes which carry it, but the nerve centres, which in later days regulate the distribution of the blood (states of dilatation and contraction of the arteries, the movements of the heart, and which must be therefore all closely associated together in their development), never reach a state of perfection. Complete control over the arteries and capillaries is therefore never the function of the vaso-motor centre in hæmophilia, and that this is the case is shown by the sphygmographic tracings. There is low arterial tension. Hence, when bleeding occurs the arteries do not contract sufficiently upon their contents owing to a want of proper impulses from the vaso-motor centre. I know not why the gums are the most usual seat of hæmorrhage in these cases unless it depend upon the rich vascular supply of their mucous membrane and the scanty support to the walls of the vessels—membranes, too, which are exposed to variations of atmospheric pressure and to all kinds of injury received during mastication.

Newcastle-on-Tyne.

[1] On microscopical examination, I find the muscular fibres of the heart of P—— smaller than those of a man of his age, but healthy. The aorta was thinner than it should be, but on minute examination it is found to be quite healthy.



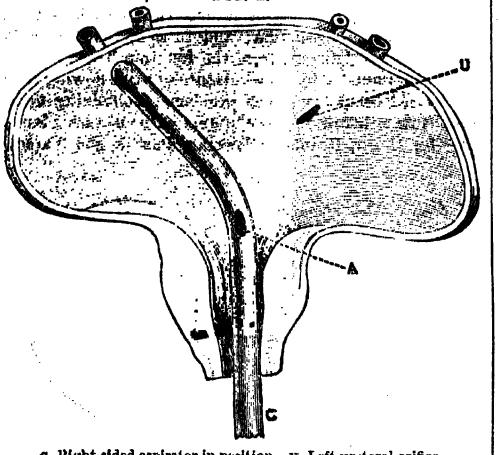
SUCTION OF THE MALE URETERS.

By E. HURRY FENWICK, F.R.C.S.,

ASSISTANT-SURGEON TO THE LONDON HOSPITAL; SURGEON AND PATHOLOGIST TO ST. PETER'S HOSPITAL.

BEFORE we attempt to excise a kidney, it is obviously of the highest importance to ascertain the existence and the working capacity of its fellow gland. Upon the capacity of the latter to bear the double burden depends the advisability of the proposed nephrectomy. Now, the stress resistance of a kidney can only be accurately gauged by a rigid examination of its secretion; and further, that secretion must be obtained directly from the fountain head; it must not be contaminated by the admixture of urine flowing from its diseased companion. The problem of obtaining urine direct from either of the *male* ureters without such admixture—for Hegar, Grünfeld, Newman, Pawlik, and Warnots

FIG. 1.



Right-sided aspirating catheter with lateral eye; end piece, to which elastic ball and glass bottle are affixed. A, the measured angle.

have shown how readily the *female* ureters may be isolated and catheterised—is as difficult as it is important. The labour expended upon the question is as yet unproductive, for the instruments, operations, and suggestions of Tuchmann, Silbermann, Ebermann, Weir, Sands, Gliick, Harrison, and others are lacking—some in simplicity, some in safety, most in success. The instrument I would submit to the profession carries out, though perhaps indifferently, what I believe to be the only feasible method for engaging and tapping the male ureters. I have had it for two years, and have proved it to be simple, easy of application, but not infallible. The principle of its action is a slight suction force which is exerted upon the ureteral orifice by means of a catheter and a small indiarubber ball. This is, I believe, an exaggerated imitation of that aspiration which the normal bladder itself exerts upon the ureters.

It will be found that the normal bladder, unless it be in

cholera, never thoroughly contracts. Moreover, the smooth muscle wall sluggishly relaxes after its expulsive effort is over. This relaxation, at the same time that it produces a partial vacuum, diminishes the sphincteric contraction of the ureteral orifices, and any urine which may have collected in those passages is partially propelled by the *vis a tergo* of the circular muscle of the ureters and partially sucked by gravity and this negative pressure into the bladder. The aspirator consists of a small elastic ball and an oval glass bottle (see Fig. 1), which can be affixed to the end of a specially curved catheter, which latter is furnished with an elongated laterally placed eye. There are two catheters, one for each ureter. The bladder is first emptied and the catheter introduced. When it has fully entered, it is steadied and rotated over at the same time by the finger and the thumb, to the right or the left side according as the right or left ureter has to be engaged. The laterally placed eye will now be exactly over the ureteral orifice, for the angle A (Fig. 1) is the same as the normal angle which the outer side of the trigone builds with the long axis of the urethra. Fig. 2 shows the instrument in place. Pressure of the right hand upon the elastic ball empties it of its air, and its stem is then affixed to the end

FIG. 2.

C, Right-sided aspirator in position. U, Left ureteral orifice. A, Opening to receive urine from ureter.

of the catheter and the ball gradually released. The air in the catheter is correspondingly exhausted and the ureteral orifice is sucked into the eye, where it can be maintained by careful management of the ball, or by gentle counter-pressure of the finger in the rectum. In ten minutes sufficient urine will have collected in the catheter—for it rarely enters the glass bottle—to admit of an examination. I have lately had this catheter double channelled, so that the urine from the disengaged ureter may enter and drain off through the orifice A (Fig. 2) into a different receptacle.

I have said that it is not infallible. Sometimes there is but one ureteral orifice, as in a case I showed at the Pathological Society (1885-86). I found the ureters in another case (Path. Soc., 1886) much displaced by the action of circum-ureteral tubercular inflammation. Sometimes small bunches of villoid or other growth in the region of the ureters (three cases, Path. Soc., 1886) prevent close application of the eye and mislead by tinging the secretion with blood. A 20 per cent. solution of cocaine renders this slight operation painless. I have used the instrument in differential diagnosis of the site of symptomless hæmaturia, also in withdrawing scraps of growth from the trigone, and in performing an operation upon the kidney, the details of which I hope shortly to publish. The instrument can be obtained from Mayer and Meltzer, 71, Great Portland-street.

George-street, Hanover-square.

A CENTENARIAN.—On the 8th inst., at the meeting of the North Dublin guardians, Dr. Kenny, M.P., reported the death of an inmate of the workhouse at the age of 105 years. He was a sailor at the time of the Irish rebellion of 1798, and smoked tobacco up to the day of his death.

A NEW METHOD OF

REMOVAL OF THE ENTIRE TONGUE BY MEANS OF THE GALVANIC (OR SIMPLE WIRE) ECRASEUR AND SCISSORS.

BY FERDINAND ALBERT PURCELL, M.D., M.CH.,
SURGEON TO THE CANCER HOSPITAL.

IN my lecture given at the Cancer Hospital on Jan. 29th I demonstrated a new method for the removal of the entire tongue and floor of the mouth—applicable for removal of one-half of the organ if necessary—and presented a series of four cases operated on last year. I have christened it the "supra-hyo-glosso-epiglottidean method," which name anatomically describes the operation. The necessity for seeking for another mode for removal of part or the whole of the tongue is not that I have relinquished operating by the Whitehead or scissors method, combined with or without the preliminary tying of the linguals, or of performing first tracheotomy with the use of Trendelenburg's apparatus as used by Mr. Barker and Professor Kocher of Bern,—but that, in my experience, it may be in exceptional cases, in operating on the tongue, especially by the scissors or Whitehead method, bleeding has been the factor most difficult to combat, and its consequent result—namely, "surgical pneumonia." "Nothing is new under the sun," as the old saying goes; nor is it so in this, for Mr. Barwell so long ago as 1879[1] described his method, of which mine is the offspring; and recently I was much struck by a paper on a "Method of Controlling Bleeding during Complete or Partial Excision of Tongue" by Mr. Jordan Lloyd, of Queen's Hospital, Birmingham,[2] in which he applies steps of my method for the controlling of bleeding from the linguals.

With this factor the bleeding it is of great importance that operations should be made easy for ordinary surgeons, and as bloodless as possible for patients whose powers have been weakened by pain, from deficient nutriment arising from difficulty of mastication and salivation, and anxiety, and who, after a severe operation, and having to submit to an absence of solid food, can be expected to bear well the loss of blood. My experience of my "supra-hyo-glosso-epiglottidean method" reduces our trouble from this source without any blood loss whatever, and by which is secured a very thorough removal of the tongue, together with the floor of the mouth and all structures down to the hyoid bone. I would recommend the surgeon, as Mr. Jordan Lloyd suggests, before attempting this procedure "to familiarise himself with the glosso-epiglottidean pouch, by palpation with an index finger introduced into its deepest part and another placed outside between the hyoid bone and the under surface of the angle and rami of the lower jaw; this anyone can try on himself; it is surprising how little tissue intervenes between the fingers, and how distinctly the various structures in relation to this space can be identified." It is necessary after removal of the tongue to have the cavity kept well drained by means of an indiarubber drain through the supra-hyoid opening, the parts dusted inside with iodoform, and the patient fed through an œsophageal tube.

The patient having been anæsthetised, first make an incision in the neck about a quarter of an inch long in the middle line from the hyoid bone forward, only skin deep; then pass a whipcord ligature through the raphé of the tongue an inch behind its tip, to hold the organ by; gag the mouth open; introduce the left index finger well to the bottom of the glosso-epiglottidean pouch, back of root of tongue. It may be necessary at this stage, so as to make room to get well round the base of the tongue, to snip with scissors the palato-glossi muscles—viz., the anterior pillars of the fauces, as also the stylo-glossi muscles of both sides; these may require pressure-forceps to be employed, as generally some small vessels may bleed; these can be taken off when wanted out of the way. Now take, say, Wood's hernia curved needle on handle, being stout, long, and well curved, threaded with medium-sized whipcord; or the needle in place of the thread may carry the platinum wire if the surgeon intends using the galvanic écraseur. Hold the needle in the right hand horizontally, its concavity turned

[1] THE LANCET, April 18th, 1879. [2] Ibid., Jan. 23rd, 1886.

upwards and towards the neck, enter its point at the submental incision immediately above the hyoid bone, pass it through the raphé of the mylo-hyoid, the genio-hyoid, and the lower fibres of the genio-hyo-glossi muscles, and direct it to the right side, forming the sweep of a half circle; now feel for the point of the needle with the left finger as the needle is pushed through so as to enter the bottom of the side of the right glosso-epiglottidean pouch above the great cornu, hook up the loop of thread, or it may be the platinum wire, with the left finger, pull it well through and out of the mouth, and withdraw the needle; do the same on the opposite side, for which it will be necessary to change the position of the hands, holding the needle in the left and placing the right index finger in the left side; a loop will in this way be lodged in the pouch at either side; thread each loop with the platinum wire, making a hook of wire by bending its end on itself; draw on both sides, so that the ends of the wire are brought out at the supra-hyoid incision, make even and detach the loops; the centre of the wire now forms a loop and rests on the base of the tongue. Before proceeding further, remove the pressure-forceps from off the cut anterior pillars of the fauces; take the same curved needle (Wood's), unarmed this time, and enter it again at the supra-hyoid incision in a vertical manner, its concavity directed towards you; feel for the point of the needle with the left finger as it is pushed through the centre of the root of the tongue and in front of the epiglottis; guard the point by means of a piece of cork, here the needle remains to act as a guide for the wire to travel behind; lodge the wire behind the guide and draw it taut, complete its connexions, and work the écraseur—the tongue is severed through its root in a well-defined vertical plane; withdraw the guide-needle. Secondly, free with scissors the anterior and lateral attachments of the tongue and floor of the mouth, release the organ and withdraw it through the lips. No hæmorrhage, as a rule, occurs; but if the battery or the écraseur should be worked too quickly and bleeding does take place, a sponge on a stick pressed into the furrow and following the wire will be found sufficient to restrain it; the linguals are included and cut through by the wire, and if they should so happen to spurt, they can be secured by pressure-forceps on the stump and tied. The ordinary simple écraseur, either single wire or twisted whipcord, may be substituted in place of the galvanic. The entire tongue may be removed as described, or the one half if so desired, by scoring the dorsum of the tongue with a blunt-pointed scalpel exactly in the middle line, and dividing the tip freely down and through the middle line of the frænum; then take both threads (one having been previously passed through each tip), one in each hand, and, using the forefingers much in the same way that one would for tightening a ligature on a deep vessel, split the tongue in two halves, and free the diseased half with scissors.

CASE 1. John M——, aged sixty-two, from Hampstead Union, was admitted into the Cancer Hospital, Ellis ward, on July 29th, 1885, under my care. Three years ago he first noticed a small ulcer at the base of the tongue, which was very painful. Has been a slight smoker. Has no history of phthisis or of syphilis. State on admission: Situate at the base of the tongue, and on the right of the median line, is an irregular excavated surface with indurated edges, its base covered with a slough. The whole extent of the ulcer cannot be fully determined; it extends as far back as the root. He cannot endure the finger to be inserted in his mouth. No enlarged glands are to be felt. He suffers great tenderness on the affected side; is unable to eat; dribbles saliva; feels weak, and is feeble and broken down; has an old ulcer on his leg. The patient was placed on the operating table on Aug. 1st. The hyo-glosso-epiglottidean operation by means of the galvanic écraseur and scissors, as described, was performed; the tongue was severed at its base, behind the anterior pillars, in a well-defined vertical plane. The action of the heated wire at first was too rapid, for it had not worked very long before some blood welled up. A stick sponge was pressed in the furrow following the wire, which restrained all bleeding; this was afterwards found to have come from a small superficial vessel immediately under the mucous membrane; the linguals gave no trouble. The mouth presented a deep excavated cavity; entire floor removed. A drainage-tube of good size was passed up through the opening in the neck, and the parts were dusted with iodoform. After twenty-four hours he was fed by means of the œsophageal tube. By the end of the month he was quite healed.

CASE 2. James W——, aged sixty-five, from St. George's Workhouse, was admitted into the Wolrige ward of the Cancer Hospital on Aug. 7th, 1885, under the care of Mr. F. B. Jessett. After operation he was attended by myself, my colleague having gone on his holiday. No history of cancer or of phthisis. Has had no serious illness. Became totally blind eleven years back. About nine months ago a pimple the size of a pea appeared on the left side of the tongue; this increased slowly. On admission there was on the left side of the tongue an ulcerated spot which could be covered with a two-shilling piece. Although it was irregular in outline, the edges of the ulcer were hard and the base uneven, being covered by unhealthy granulations. Situate beneath the extreme angle of the ramus of the right jaw a gland was enlarged, and another beneath the jaw on the left. On Aug. 11th the operation for entire removal of the tongue by the method described by means of the galvanic écraseur and scissors was performed. The gland on the left side was removed by an incision, and the wound sutured and sealed with styptic collodium. The gland of the right side was fished out of the floor of the mouth by the finger. The linguals spurted, but were seized in pressure-forceps and tied. Little blood was lost. A drainage-tube was passed up through the opening in the neck. The patient made a good recovery.

CASE 3.—Joseph R——, aged sixty, married (from Caerphilly, Cardiff), was admitted into the Cancer Hospital, Ellis ward, on Aug. 22nd, 1885, under my care. There was no history of phthisis or of syphilis. He never suffered from any serious illness. Has been a heavy smoker. His father had epethelioma of the lip; his mother died of old age. About nine weeks ago he first noticed that his tongue was being irritated by the teeth, two of which he had removed. The tongue, however, got worse, and rapidly ulcerated. The pain was severe, and he was greatly worried by continual dribbling of saliva. On admission, the tongue was fixed at the left side; ulceration, with induration extending back to the root, engaging anterior pillar and neighbouring soft palate; glands to be felt below mastoid process; emaciation; unable to masticate any food; was suffering great pain. On Aug. 29th I performed the hyo-glosso-epiglottidean operation, using the wire écraseur (instead of the galvanic) and scissors. The patient breathed badly under the anæsthetic. When about one-third through the tongue, the forcible constriction apparently closed the rima glottidis and caused asphyxia. The écraseur was not worked while artificial respiration was being performed. The patient looked bad, but had a capital pulse at the time. I proceeded to perform tracheotomy, and had made the incision, when the patient took in an inspiration, and a second, on which I desisted. I again worked the écraseur, pressing it upwards in place of pulling on the instrument; this being completed, the wire guide was removed, the anterior and lateral attachments were cut with scissors, and the tongue, released, was withdrawn. The lingual on the left side, having spurted, was seized and tied. The specimen was examined; it was found that the disease was not all removed. Using Paquelin's cautery, the parts were freely burnt, including the surface of the jaw-bone, as also the anterior pillar of the fauces and neighbouring soft palate; this worked away the structures to a much lower level on the diseased side, and by removing a piece somewhat larger than a walnut a clear view into the pharynx was obtained. A drainage-tube was then passed through the opening in the neck, and the parts dusted with iodoform. The patient made a good recovery.

CASE 4.—Joseph S——, aged forty-seven, married (from St. Paul's-road, Bristol), a sailor, was admitted into the Cancer Hospital on Aug. 25th, 1885, under my care. The right side of the tongue was ulcerated; induration and fixation of the organ on the same side; remains of a recent incision; glands enlarged on left side. No history of cancer or phthisis; always enjoyed good health; is a heavy smoker; usual stimulant is rum. About seven months ago he first noticed a small warty growth at the base of the tongue; this shortly afterwards disappeared. Then a lump came on the right side of the neck, the tongue became painful at the right side, and a white streak appeared. He was at the time on the coast of Africa, and was advised by his doctor to go home. He returned to Bristol and was admitted into the Bristol General Hospital, when the small growth was removed from the side of the tongue on April 2nd, 1885. After operation he suffered great pain, and on Aug. 11th the gustatory nerve was cut. State on admission: A strong healthy man.

Opposite the first molar tooth on the right side is a fissure extending as far as the median line; beneath surface ulcerated; organ bound down to floor of mouth; one or two glands enlarged below jaw. On Sept. 1st I performed this operation with the galvanic écraseur and scissors, severing the tongue close up to the epiglottis. One lingual spurted, and was tied. Where the tongue had been adherent on the right side, the parts were freely burnt with Paquelin's cautery, a drainage-tube passed up and the parts dusted with iodoform. He was fed during the night with nutrient enemata; next morning by means of the œsophageal tube. — Sept. 7th: Temperature 101°; some pneumonic râles; was delirious during the night.—22nd: Has passed through an attack of pneumonia; dulness still of the right side; inserted a hypodermic syringe needle into the right pleura, withdrew only a drop or two of pale fluid.—24th: Situate on the right side of the floor of the mouth there is a recurrent growth of the size of a hazel-nut.—Oct. 2nd: Had a copious discharge of purulent sputa; great fetor of breath; evidently an abscess of the lung has burst.—3rd: Had a rigor this morning; temperature 102·6°; right side of the chest fuller than the left. To inhale iodine vapour.

The patient eventually recovered. I had him again anæsthetised, and with Paquelin's cautery freely cauterised the floor of the mouth, destroying the recurrent growth. He afterwards made a good recovery, and left the hospital about Christmas. My patient replied to a query that appeared in *Tit Bits* as follows:—"Sir,—*Re* question 1926 of Nov. 21st, 1885, it may be interesting to your readers to know it is quite possible to talk without a tongue. The writer has not a particle of tongue remaining, as it was removed recently at this hospital on account of cancer. I may add I still retain a sense of taste and enjoy a capital appetite. I shall be pleased to answer any further questions on this matter, and if you think fit to publish this you are quite at liberty.—Yours, &c., Captain S——, Wolrige ward, Cancer Hospital, S.W."

PARALYSIS DEPENDING UPON IDEA.

BY C. W. SUCKLING, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

IN the *Birmingham Medical Review* for June, 1885, I published an account of a boy who had suffered from paralysis of one leg for two years, and whom I was able to cure immediately after making the diagnosis of paralysis depending upon idea. Since then I have met with three other cases, two of which were men. In one case there was complete anæsthesia of the hand; in another hemi-analgesia with localised and severe headache. In the four cases I have now seen, an accident occasioning slight injury was the exciting cause in each. All four cases were rapidly cured. Dr. Russell Reynolds, I believe, first described paralysis depending upon imagination. There is no malingering in these cases, but the patients are firmly convinced that they are suffering from paralysis. If the confidence of the patient be gained, an immediate recovery follows when he is told that he will be well immediately, the idea being got rid of. In making the diagnosis it is important to bear in mind the two classes of people in whom functional nervous disorders are met with—the neurotic and the hysterical; the features of which have been so graphically described by Dr. Clifford Allbutt in the Gulstonian Lectures for 1884. It is the neurotic that is apt to be affected by these paralyses depending upon idea, and it is these cases that are instantly cured when the diagnosis is made. The hysterical patient is cured with difficulty and frequently relapses; the neurotic does not relapse. The neurotic individual is vivacious, good-tempered, unselfish, intelligent, active and industrious, anxious to be cured, and grateful for recovery. The hysterical individual is listless, apathetic, lazy, selfish, with characteristic expression, not usually anxious to get well or thankful for recovery. The following is the fourth of these cases of paralysis depending upon idea that I have met with during the last twelve months.

Sarah F——, a widow, aged forty-six, was sent to the Queen's Hospital, to be admitted under my care, by Dr. Middleton, of Harborne, on the 15th of March last, and was discharged well on March 28th. She has led a very industrious life, having supported her five children by needlework since her husband's death ten years ago. On Oct. 9th, 1885, she tumbled downstairs, falling down twenty-one steps on to her back. She was much hurt and "dazed" and very much frightened, thinking every bone in her body was broken. She walked about after the accident for a day or two, but suffered from pains in the back, down the legs, and round the body; these pains were intermittent, very severe, and lasted altogether three weeks. Two days after the accident she took to her bed, and a day or two later found that she was paralysed in both her legs and had lost all feeling in them. Since the accident she had suffered from constant headache and backache. Upon examining her I found that she had a little power over the legs, but very little. Slight ankle-clonus could be elicited on the left side. The plantar and abdominal reflexes were lost, but the knee-jerk was well-marked. There was complete analgesia and thermal anæsthesia in both legs up to the knees. She was unable to localise tactile sensations below the knees, the anæsthesia not being complete. When touched with a sharp-pointed instrument she said she felt as if she were being pushed. Muscular sense was unaffected. There was superficial tenderness over the lower dorsal spines, but no pain on firm pressure or on percussion, and no irregularity of the spine. The bladder and rectum were unaffected, and I was informed by Dr. Middleton that she never lost control over the bladder, nor had any sign of bedsore during her illness. There was no œdema of the legs, no alteration of temperature, and no change in the colour or aspect of the skin or nails. In fact, there were absolutely no trophic changes whatever. The response of the muscles to faradisation of their nerves was normal, but there was considerable electrical anæsthesia. In summing up the symptoms present, I of course observed their incongruity if we supposed the case to be one of myelitis, or, in fact, as due to any organic lesion. If the anæsthesia were due to actual lesion of the grey matter, how could the bladder and rectum escape? How was it that there was no sign of bedsore, no œdema, or other trophic changes, such as muscular wasting? I diagnosed the case immediately as being purely functional, and, the woman being of the neurotic type, as paraplegia depending upon idea. I at once acted upon this diagnosis, and told the patient that I should give her the battery, which I said would at once remove the loss of sensation and enable her to move her legs as well as she ever did. She was delighted to hear this, and after a minute's faradisation sensation was completely restored, and she had full command over her legs. I then told her that on my next visit I should expect to see her walking about the ward, for I was sure that she would be able to do so. I instructed Mr. Whittendale, my house-physician, to see that she got up after I left, and to apply the faradaic current whenever she displayed any hesitancy. On my next visit, two days later, I found her up and able to walk and run about the ward perfectly well. She was quite delighted at her recovery, and had been most industrious with her needle since getting up. She expressed deep gratitude, and hoped to be able to repay our kindness. I may add that I saw my patient on the 14th of the present month (September), and she was remaining quite well.

How was the cure effected in this case? Undoubtedly, I think, it was by the mental state of faith or expectation, or both, on the patient's part. She fully believed what I told her, and thus I was able to remove the idea she had that she was paralysed. The essential thing, then, in these cases is to make a correct diagnosis, and then the patients can safely and with success be told that they will quickly recover. Now, had this been a hysterical woman, I should in all probability have failed to cure her, or, at any rate, the cure would have been more tedious. I recently had a woman under my care suffering from locomotor ataxy with hysterical anæsthesia. For two years I did all I could to cure the anæsthesia, and failed; but when she left the infirmary she applied leeches to her legs and returned with the anæsthesia gone. Isolation, so useful in hysterical cases, is not needed in these.

In the same ward with my case of ideal paralysis there was a young woman suffering from hysterical neuralgia, and the contrast between the two patients was very marked. The hysterical woman was listless and apathetic, did not manifest any desire to be cured, and would scarcely allow that she was any better than when admitted. When told that she was well enough to go back to her duties as a

teacher, she seemed disappointed, and said that she did not intend to begin work again for some months. The neurotic woman, on the contrary, wanted to leave the hospital immediately she could walk. The hysterical woman was observed to be always sitting opposite the neurotic woman, contemplating her with her hands idly folded in her lap, watching the other busily working.

Such cases as these illustrate the enormous influence of the mind over the body. It is with these cases that the so-called faith-healers work pretended miracles. What an opportunity for a faith-healer my case would have afforded! Just as the mind has an enormous influence in causing disorders of sensation, of motion, and also of the organic functions, so also its influence can be used as a practical remedy in disease. As Dr. Wilks has well observed, "the practice of medicine is not only one of physic, but of psychology also."

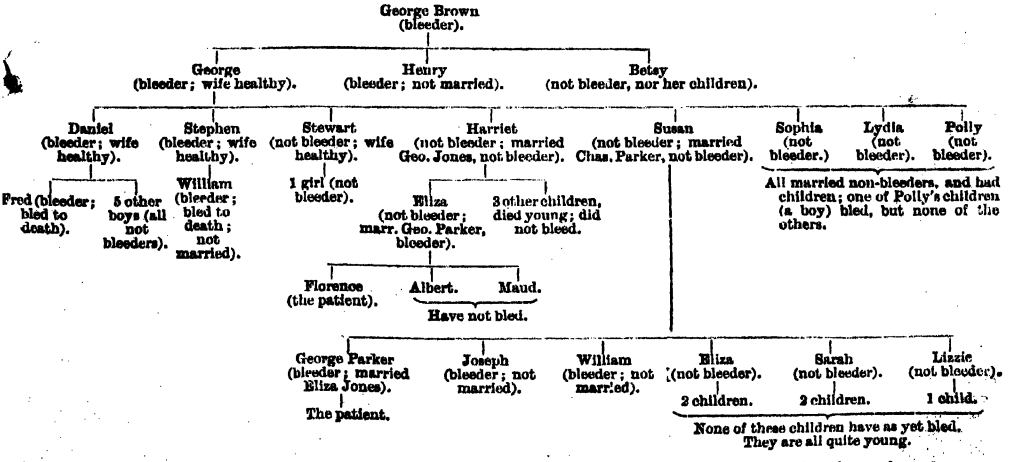
A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prœmium.

LONDON HOSPITAL.

A CASE OF HÆMOPHILIA; PEDIGREE THROUGH FIVE GENERATIONS.

(Under the care of Mr. FREDERICK TREVES.)



THIS case of hæmophilia is interesting, as Mr. Treves remarks, from the sex, and from the clear account of the pedigree of the patient which is appended, and which shows so well the transmission of the disease from parent to children. It is seldom that the most assiduous search can trace the family history of any case so far back, especially when the patient comes from the rank of life to which this girl belongs.

Florence P——, aged six, was admitted on January 26th, 1886, under the care of Mr. Treves, for obstinate bleeding from the mouth. On Jan. 24th the right second molar of the lower jaw had been extracted. Within an hour and a half after the operation the socket began to bleed; there was little or no bleeding at the time of the extraction. The socket was plugged and the hæmorrhage was checked for some twelve hours. It recurred, but ceased after a second plugging. There was no bleeding for the next twenty-four hours. It then reappeared, and all means adopted to check it failed. The hæmorrhage had been considerable; large clots of blood had formed in the mouth and had been removed from time to time. On admission the patient was perfectly blanched and in a dangerously exhausted condition, a little watery blood still oozing from the mouth. The child was well developed and of fair complexion, the eyes being blue and the hair very light; the skin was singularly smooth and delicate; the teeth were well formed. The child had always enjoyed good health. No enlarged glands had been felt in any part. The extremities had been always of normal temperature. The patient did not complain unduly of cold, and had never had chilblains. She had never bled before, nor had unusual ecchymoses followed casual contusions. She was not an excitable child, and appeared to be in perfect health when the bleeding commenced. The tooth was extracted entire and without difficulty. The father and mother were first cousins. They were natives of Essex, and in that county the family had resided for many generations. Both parents enjoyed good health. The father had suffered from three attacks of bleeding, and each time had nearly lost his life. On the first occasion there had been a cut on the thumb, on the second a cut of the index finger, and on the third a tooth had been extracted. The parents were members of a well-known "bleeder" family. There were two other children besides the present patient. They were infants, and had never bled.

The socket of the tooth was very carefully plugged with ferrated cotton-wool. Ergotine and gallic acid were administered. The child bled slightly on three occasions between Jan. 26th and Jan. 31st, the hæmorrhage each time being arrested by plugging with ferrated cotton-wool. The child left the hospital on Feb. 8th, no blood having been lost for eight days, and no plug having been used for that length of time. She was still very weak and anæmic, and was taking a preparation of iron.

Remarks by Mr. TREVES.—Three cases of hæmophilia have come under my care in the hospital during twelve months. The present example is the most noteworthy, inasmuch as the patient was a female, and a very complete history of her family was provided by her mother and grandmother. The researches of Grandidier, Wachsmuth, Wickham Legg, and others have served to display the remarkable heredity of this disease and the still more remarkable manner in which it is transmitted. It is known that the affection cumulates in certain families—the so-called bleeder families; and statistics show that there are nearly three bleeders to every family affected. The disease, moreover, is thirteen times more common in males than in females. It has been clearly proved that it is transmitted not so much by the bleeders themselves as by their non-bleeder brothers and sisters. The extraordinary fruitfulness of the latter has often been marked. Wachsmuth states that the average number of legitimate births in bleeder circles is nearly double the ordinary average. In the transmission of the disease the preponderance of the maternal

PEDIGREE OF THE FAMILY OF FLORENCE P——.

influence is very conspicuous. It may be almost said that the females hand down the disease, while the males are the victims of it. Grandidier has formulated the following points in this connexion:—1. Males in bleeder families who are themselves bleeders do not as a rule beget bleeder children by women who belong to non-bleeder families; in fact, the children in this case are usually healthy. On the other hand, the children of women who are themselves bleeders are quite uniformly subjects of hæmophilia. 2. Males in bleeder families who are not bleeders almost never beget bleeder children by women from other families. On the other hand, among the children of women who belong to bleeder families without being themselves bleeders, there are almost always some who suffer from hæmophilia. The family history of the present patient affords an interesting comment upon these statements. (In the Table the actual Christian names have been preserved, while the surnames are fictitious.) It will be seen how the females of the family were free from the disease, while nearly all the males were subjects of it. So far as the pedigree extends no female had hæmophilia until two first cousins married. The present patient was their eldest child. It will be seen also that in several instances male bleeders who married healthy wives had children who were the subjects of this disease; while, on the other hand, by no means all the children of the females of the bleeder family exhibited the phenomena of hæmophilia. (See pedigree.)

ST. MARY'S HOSPITAL, MANCHESTER.

CASE OF ALBUMINURIA DURING PREGNANCY; INDUCTION OF PREMATURE LABOUR; RECOVERY.

(Under the care of Dr. C. J. CULLINGWORTH.)

For the notes of the following case we are indebted to Dr. Archibald Donald, house-surgeon and resident assistant obstetric surgeon.

E. M——, aged twenty-six, a cheerful, intelligent, well-nourished young woman, pregnant for the first time, was admitted into the hospital, March 5th, 1886, suffering from extensive anasarca. She had been married about ten months, and had last menstruated on Aug. 20th, 1885. The fundus uteri reached to an inch above the umbilicus; the fœtal heart sounds and uterine souffle were both audible. The first symptoms of swelling were noticed in the feet six weeks previous to her admission. Within a few days from that time the swelling had become very marked over the whole body, the face, hands, trunk, and legs being all implicated. It was not until a few days before her admission that she observed the urine to be scanty and high-coloured. She had not felt fœtal movements, and was, in fact, not aware that she was pregnant. Her health before this illness had been uninterruptedly good.

On admission, there was very considerable œdema of the whole surface of the body; the eyelids were greatly swollen, as well as the trunk, and all the extremities. There was also evidence of a considerable amount of ascites. The urine was brownish-red in colour, acid in reaction, of sp. gr. 1020, and became almost solid on the addition of nitric acid. In the sediment were found blood-corpuscles, tube-casts (hyaline and blood), and renal epithelium. A consultation was held, and it was decided, before adopting means to cut short the pregnancy, to try the effect of rest in bed and medicinal treatment. Accordingly, hydragogue cathartics were administered, and hot-air baths. Subsequently nitrate of pilocarpine, in doses of one-third of a grain, was injected subcutaneously once a day for three days. As this had no effect whatever, the liquid extract of jaborandi was given by the mouth, with an equally disappointing result. Indeed, of all the means that were tried, dry cupping over the loins and over the bases of the lungs, was the only one that was followed by even temporary benefit. The anasarca meanwhile increased, and œdema of the lungs set in, with great dyspnœa, and a most harassing and constant cough. The patient was unable to lie down night or day, and became so weak that the urine was from time to time expelled involuntarily. The skin was very dry. The temperature did not rise much above 100°.

On March 16th (eleven days after admission), matters had become so urgent that Dr. Cullingworth gave directions for premature labour to be induced without further delay. Accordingly, at 9.30 P.M., a gum-elastic bougie was passed to the extent of about six inches into the uterus. Pains commenced at 2 A.M. on the 17th; at 6 A.M. they had become severe; at 7 A.M. there was an attack of hæmorrhage, one or two large clots accompanying it; a few minutes later the membranes were ruptured spontaneously (the os uteri being nearly fully dilated); and at 7.40 A.M. a living fœtus of apparently between six and seven months was expelled naturally. The placenta not having come away in due time, expression was tried, but without success. The hand was accordingly introduced, and it was then found that the placenta was partially adherent to the posterior wall of the uterus, just above the internal os. After detaching and removing the placenta, the uterus was injected with hot carbolised water. The amount of hæmorrhage during the third stage of labour was considerable. In the evening the dyspnœa and cough were very troublesome, and the patient was very restless. This condition lasted for several days. During the two days following confinement 160 oz. of urine were drawn off. (The average daily quantity a few days before labour was 25 oz.) The anasarca now became speedily diminished. On March 23rd, the patient's general condition was much improved, the dyspnœa having quite disappeared and the cough being much better. The amount of albumen in the urine was now reduced to one-sixth; the daily quantity of urine was about 68 oz., and the specific gravity about 1010. The colour was light yellow; no casts were discoverable. From this time convalescence was established very rapidly. On April 10th the last trace of albumen had disappeared from the urine, and on the 17th the patient was discharged well. The child only survived its birth about thirty hours.

Remarks by Dr. CULLINGWORTH.—There are several points of interest in this case. 1. It affords a striking illustration of the fact, already well known, that very pronounced albuminuria may exist during pregnancy without eclampsia. The urine here was loaded with albumen, and the œdema was intense; yet not only were there no convulsions before labour, but (what is more important) none were excited by the manipulations necessary for inducing premature labour. How far we have to thank the exceptionally cheerful and placid disposition of the patient for this immunity I cannot say. It is quite possible that the absence of anything like extreme previous irritability was the one fortunate circumstance that saved the patient from convulsions. 2. It is to be noted how completely all palliative measures failed so long as the pregnancy continued. I was particularly struck with the utter uselessness of pilocarpine in this case. The beneficial results obtained from its administration in puerperal eclampsia by Horrocks[1] and Murphy[2] naturally encouraged the hope that equally satisfactory effects would follow its use in uncomplicated cases of the acute albuminuria of pregnancy. The case here recorded seemed to afford an excellent opportunity for teaching how far such a hope is likely to be realised. Three injections of a freshly-made solution obtained specially for the purpose, were administered in doses of one-third of a grain at intervals of about twenty-four hours. No appreciable effect followed. The result seems also to show that further evidence is necessary before Dr. Horrocks's statement as to the ecbolic action of pilocarpine can be accepted. 3. The prompt recovery of the patient as soon as the uterus was relieved of its contents (notwithstanding the loss of blood occasioned by the faulty position and adhesion of the placenta) points to the induction of premature labour as the proper and hopeful treatment in severe cases, where other and less radical measures have been fairly tried and found useless.

[2] Ib., May 29th, 1886.

LIVERPOOL HOSPITAL SUNDAY FUND.—At the meeting of the committee of this fund held last week it was reported that the total amount for disposal was £9250, as against £8880 last year. It was unanimously resolved to hold over for further consideration a grant to the Hospital for Women in Shaw-street, but amongst the awards granted were the following:—Royal Infirmary, £2312 10s.; Royal Southern Hospital, £1387 10s.; Northern Hospital, £1202 10s.; The Dispensaries, £647 10s.; Infirmary for Children, £555; Stanley Hospital, £462 10s.; Eye and Ear Infirmary, £462 10s.; Hospital for Consumption, £277 10s.; St. Paul's Eye and Ear Hospital, £138 15s.; Hospital for Cancer and Skin Diseases, £92 10s.; Netherfield Institution for Infectious Diseases, £92 10s.; Dental Hospital, £23 2s. 6d.; St. George's Hospital for Skin Diseases, £23 2s. 6d.

Reviews and Notices of Books.

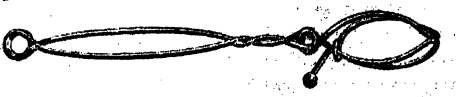
On Cancer of the Mouth, Tongue, and Alimentary Tract: their Pathology, Symptoms, Diagnosis, and Treatment. By FREDERICK BOWREMAN JESSETT, F.R.C.S., Surgeon to the Cancer Hospital, Brompton. With numerous illustrations. London: J. and A. Churchill. 1886.

THE aim of this book has been to discuss our present knowledge and views of the treatment of cancer of the mouth, tongue, and alimentary canal. The author states that he knows "of no separate work or monograph which treats specially on this very important subject"; and he adduces this fact as the ground of his choice of a subject for his monograph. To many people it will appear to be a strong reason why such a book was not particularly called for. We can well conceive the value of a treatise on cancer in general in which the peculiar pathological and clinical features of this dread disease are discussed. We can also appreciate the advantage of monographs devoted to the affections of particular organs. But we know of no reason why a book should be devoted to the consideration of one particular disease as it affects such a series of organs as Mr. Jessett has chosen, especially when no attempt is made to show any leading pathological or clinical features common to the whole. But, after all, the book is before us, and we are more concerned with what Mr. Jessett has written than why he has written it. Some of the most important surgical diseases are embraced in the author's group, and any careful discussion of the diagnosis and treatment of cancer of the tongue and rectum or of the best modes of dealing with malignant stricture of the pylorus and œsophagus must be of interest to surgeons. We find a table of over fifty cases of cancer of the tongue submitted to operation, and another of sixty cases of gastrostomy for cancer of the œsophagus, which have been collected from various sources. These are good features of the book, as are the statistics culled from the note-books of the Cancer Hospital. But having said this, we are afraid we cannot add that Mr. Jessett has added materially to our knowledge of the diseases about which he has written. He leaves us a little uncertain as to his opinion on the much-discussed question of the local or constitutional nature of cancer. Thus on page 88 we read in respect to cancer of the tongue: "I, however, regard the disease as a local affection, so far as it does not, or very rarely, attack any other organ in the body; and I therefore consider, if the disease is removed early enough and thoroughly, there is little chance of its returning in the site of the cicatrix." And on page 90 we read: "I believe it to be a constitutional (I use the word in its widest sense) and not a purely local disease."

Some novel and important views in reference to tubercular ulceration of the tongue are advanced, first as to the mode of origin of this disease, and then as to its relation to epithelioma. Mr. Jessett states that a tubercular ulcer on the tongue is always secondary to deposits of tubercle in the lungs, and in this he is in accord with other observers. But he goes on to suggest that "the ulcer is originally a simple one, and becomes tubercular by being inoculated by the bacilli in the sputum which is continually being ejected from the lungs." And on the very same page we read: "The ulcer commences in the submucous tissue, usually as a smooth, hard nodule"—a statement directly opposed to the former view, and indicating that the ulcer is formed by the disintegration of a tubercular nodule.

Of more consequence is the assertion that "tubercular ulcers are very liable to take on a malignant character." This opinion is strongly expressed (p. 70), and upon it is founded the advice to excise obstinate tubercular ulcers. "I would therefore, in cases of tubercular ulcer, unless it speedily heals under treatment, strongly recommend its early removal." Mr. Jessett does not offer any evidence in support of this view, and he does not give his readers the facts which have led him to form his strong opinion. In the absence of such evidence he has taken upon himself a very grave responsibility in urging the excision of tubercular ulcers. Indeed, the reasonableness of this advice is hard to perceive, especially from the author's standpoint. For he insists, first of all, that such patients are always the subjects of pulmonary tubercle, and that the ulcers on the tongue begin as simple ulcers and are then infected. If so, the excision of a tubercular ulcer must leave behind a simple ulcer which is constantly exposed to infection from tubercular sputa. On all grounds, therefore, we hold that such a statement as this should not have been made without distinct and even strong evidence to support it.

Among the means of relieving the pain in cancer of the tongue, division of the gustatory nerve is of course mentioned, but we are surprised that Mr. Jessett does not refer to the ease with which the nerve can be found where it lies along the under side of the tongue; one great advantage that operation upon the nerve here has over Hilton's and Moore's methods is the fact that a considerable length of the nerve can be excised.



How to Foretell the Weather with the Pocket Spectroscope. By F. W. CORY, M.R.C.S., F.R. Met. Soc., &c. London: Chatto and Windus.

METEOROLOGICAL SCIENCE, which until a few years back had but few votaries, has recently given signs of vigorous life, and the daily weather forecasts are now probably as diligently scanned as the quotations of the money market. There is more satisfaction, however, in making weather observations for oneself, and Mr. Cory, in the *brochure* under notice, describes lucidly and minutely how such observations may be made with the hygro-spectroscope, an instrument the use of which, the author believes, will mark the commencement of "a fresh branch of meteorology that will eventually supply the missing link in forecasting, annihilate its difficulties, and bring to our knowledge facts about the upper regions of the atmosphere that were never dreamt of in our philosophy." The spectroscope, however, it must be stated, is not extolled as an infallible indicator of the kind of weather in the near future, but only as a valuable adjunct to other means of forecasting. In the rush of modern daily life, when arrangements for business or pleasure have to be made to fit in with seasons of routine work, the advantage of being able to anticipate with some degree of certainty the sort of weather approaching cannot be doubted, and this power the little work of Mr. Cory's will go far to put within the reach of those who will take the trouble to master its contents.

New Inventions.

NEW SPONGE-HOLDER AND DRESSING FORCEPS.

THIS simple instrument (which has been designed by Dr. J. Ward Cousins) will be found very useful in many surgical operations. It is made of twisted wire, and the grip of the blades is sufficient for holding securely sponges

of various sizes and pledgets of cotton-wool. By pressing the thumb on the spring the points are relaxed, so that the material can be charged with great facility. It is manufactured in several sizes by Messrs. Maw, Son, and Thompson.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 18, 1886.

Two gentlemen are specially entitled to the thanks of the country for their speeches on the motion of Mr. ARTHUR O'CONNOR for withholding £16,500 of the grant of £445,956 for the Local Government Board. The £16,500 is the sum given to vaccination officers. In the estimation of this gentleman it is the mainstay of an immoral, stupid, and cruel system, inflicting immense physical suffering on great numbers of persons and the greatest amount of mental anguish on parents. The two gentlemen to whom the country is so much indebted are Mr. ARTHUR O'CONNOR himself on the one hand, and the President of the Local Government Board, Mr. RITCHIE, on the other. Mr. ARTHUR O'CONNOR, by his exaggeration of language, error of reasoning, absurd abuse of the medical profession, and utter want of sense of proportion in regard to human ills, was kind enough to do service to the cause of vaccination and common sense, albeit, as he tells us himself, he is the son of a physician, and has other relations with a profession whose greatest achievement he is so incapable of appreciating. Let us take one specimen of his statements and his reasoning:—"This vote makes it the interest of hundreds of thousands of educated and refined men to sanction and maintain, and almost to insist upon, the systematic prosecution, fine, imprisonment, &c., of parents, &c." What importance can attach to the words of a speaker who can condense so much error into a sentence as there is in this? Hundreds of thousands of educated and refined men demoralised by £16,000! Let us analyse this nonsense. Probably about one medical man in twenty is a vaccination officer. The nineteen are deprived by the system denounced by Mr. ARTHUR O'CONNOR of the chance of public payment for vaccination; more than this, they are deprived of cases of small-pox, which are far more lucrative to the medical profession than cases of vaccination. Then, to crown all, there are no hundreds of thousands in the profession, but only 25,000 in the three divisions of the United Kingdom. We beg to assure Mr. ARTHUR O'CONNOR that the medical profession is not so easily demoralised. It is only fair to say that several members of Mr. O'CONNOR's own party in Parliament disclaimed and thanked him for his views. Mr. RITCHIE is as much to be thanked for showing the strength of the case for vaccination as Mr. O'CONNOR is for exhibiting the weakness of it and of those who oppose it. The former gentleman made an admirable statement. The demonstration that but for vaccination 12,000 more children would have died of small-pox in a given year than did die of it was crushing. The champions of vaccination can afford to allow an occasional death from faulty vaccination, though that is a rare an occurrence that men who have been nearly half a century in practice have not seen it. The system of rewards for vaccination has for its object the prevention of such accidents, by the encouragement of the most effective and perfect vaccination. The facts about the case of the great city of Philadelphia come opportunely to hand at this moment. There has not been a single case of small-pox in that city. The control of the disease is due to the use of what Mr. ARTHUR O'CONNOR is pleased to call the "filthy rite" of vaccination. It is stated, says *The Times*, quoting a Philadelphia paper, that if the "health officer of the city receives in his morning mail news of a suspected case of small-pox, he at once sends word to the vaccine physician of the district to visit the suspected house and neighbourhood, and vaccinate all who are not evidently well protected by this operation against the disease. The agents of the board are at once despatched to thoroughly disinfect the suspected premises, and to insist upon their being placed in proper sanitary condition. Later in the day the proper officer is sent to investigate the nature of the case reported. The result is that, whether the case be small-pox or not, vaccination and disinfection are secured." Mr. ARTHUR O'CONNOR, in spite of his exhaustive investigation of the subject, will perhaps be surprised to learn that the enlightened people of Leicester, whom he holds up to admiration, are protected in the same way as those of Philadelphia. The "filthy rite" saves the city. Any case of small-pox occurring in Leicester is immediately reported (see THE LANCET of June 5th), and all the powers of JENNER and vaccination are immediately brought to bear on all exposed persons. All the staff of officials—officers of health, nurses, and sanitary inspectors—surrounding the case are protected by the "filthy rite" doubly performed—that is, they are *revaccinated*. And but for this protection, "dispraised" by Mr. ARTHUR O'CONNOR—"no small praise,"—the plague would spread in Leicester as elsewhere. There is something almost mean in withholding these facts if they are known; and the gentleman who does not know them has no right to take up the time of the House of Commons in September, or any other month, in arguing for or against vaccination. To the credit of the House, Mr. O'CONNOR's motion was negatived without a divi. If any member of the House has still any doubt on the economy of the vote, let him consider the cost of an epidemic of small-pox to any town, the paupers that it makes, and the misery that it entails.

THE recent meeting at Birmingham of the British Association was, both in the scientific and social sense, a great success. The great midlands town spared no labour and no expense, and the inhabitants vied with one another in hospitality to the visitors. Many important papers, accompanied with an unusually small proportion of rubbish, were communicated to the sections, and discussed in a fairly satisfactory manner, considering the limits of time. All the presidential addresses were valuable, even those which were most speculative in their character. Modern inaugural addresses seem to divide themselves mainly into those which present summaries of recent progress, and those which sketch out promising lines for future work. The discussion of details, even details of the highest importance, belongs more properly to the work of the sections, or to the societies which deal with separate branches of science. The latter kind of address is probably the most useful "for the advancement of science," for abstracts of recent discovery can be

compiled by anybody, whereas it takes a master to guide others forward.

We have said that all the presidential addresses were good, and several of them were highly speculative, but there was one, that of Mr. CROOKES, in the Chemical Section, which was more important and more interesting than all the others. It was, indeed, a contribution to science which can never be forgotten, and which is not improbably destined to stand permanently as a landmark in scientific history; for in it there was for the first time presented a well-based, intelligible, and coherent hypothesis to account for the genesis of chemical elements, and so for the existence of matter as we know matter. As hypothesis it was put forward and must remain until further discovery dethrones it or raises it to the rank of a theory. Listening to it was listening to the first chapter of Genesis, the dim record of a time "when the earth was without form and void." For it dealt with antiquity, compared with which the earliest geological records are modern history, and afforded scope for scientific thought in a region in which dreams only had before been possible. We came face to face with the primordial matter, the "protyle," to adopt Mr. CROOKES's happy coinage, from which the chemical elements have developed and are still elsewhere in space developing, and found ourselves furnished with a scheme of evolution which gives a rational though hypothetical explanation of many facts which had long tantalized us by being at once simple and incomprehensible. To say that we have solved the enigma of physical existence would of course be absurd. Given the ultimate particles of "protyle" from which elements are generated as compounds are from elements, and we are still no nearer to the infinitely small—are still, indeed, at an infinite distance from it. Infinite space, as infinite time, defies us, and each particle of Mr. CROOKES's "protyle" is perhaps a universe to particles still smaller. But it is much to find our empire of thought and study so greatly extended, and still more to find that rich mines of discovery seem to await us in the new territory.

It is all but impossible in the space allotted to us to give even an outline of the new apocalypse of chemistry which Mr. CROOKES's generalisations, based partly on the discoveries of others and partly on his own elaborate scientific work, present to us, and we can but hope that every man who loves science will study the address for himself. But a few remarks will not be out of place, and may serve to indicate the lines of research which seem opening to chemical science.

The conception of a single element—that is, of a simple matter analogous to the protoplasm of the physiologist—is by no means new to science. It is indeed difficult for the mind to rest satisfied with the idea of an apparently capricious number—say seventy—of elemental forms of matter, some being abundant and some exceedingly scarce which limit creation and are primordially different. But they had to be recognised as elements, and their combining weights, called for hypothetical reasons atomic weights, have been ascertained with greater or less accuracy by the expenditure of an almost incredible amount of human skill and labour. The atomic weights are very diverse, and at first appeared to have no relation to one another. The hypothesis of PROUT, in the early days of exact chemistry, suggested that they were all multiples in whole numbers of the atomic weight of hydrogen. This hypothesis has been a battle-field for chemists. STAS demolished it, but subsequent researches have thrown doubt even upon the position of STAS, that most laborious of chemists. Then it was perceived that numerical relationships, too close to be accidental, existed among the atomic weights; that, for example, the atomic weight of sodium was the mean of those of lithium and potassium—elements which resembled it closely. Other elements, such as nickel and cobalt, which were very similar in chemical character, were found to have almost exactly the same atomic weight; while sulphur, the compounds of which had many points of analogy with oxygen, had exactly twice its atomic weight. Then in 1863 came the important observation of NEWLANDS, which has since proved so pregnant with discovery, that the atomic weights, starting from lithium, formed octaves, or series of seven, in which the eighth resembled the first. This periodic law was extended by MENDELIEFF, whose name is often, but most unfairly, affixed to it; and it is from this law that CROOKES's generalisations started. Adopting but modifying a graphic table recently suggested by Professor EMERSON REYNOLDS, Mr. CROOKES showed that a vibratory or pendulum-like motion of the primordial matter, or protyle, with progressive fall of temperature, afforded a possible explanation of the genesis of elements. At a temperature higher than any known on earth, with a wide swing of the pendulum, hydrogen, or perhaps the helium supposed to exist in the sun, was first formed by condensation. Then followed lithium, glucinum, boron, and the rest, as the temperature fell; until at last, when uranium, with its enormous atomic weight, was generated, the temperature had fallen so low that the elements themselves began to combine into compounds, new elements being no longer produced. Keeping to the pendulum illustration, it will be seen to be possible that at similar points of the right- and left-handed swing similar elements might be developed with atomic weights increasing periodically as the temperature fell. In the diagram which accompanied the paper, which was no fancy sketch, but an accurate representation of the atomic periods on a pendulum the arc of which was diminishing uniformly, the elements are seen in places singularly in accord not only with their atomic weight, but also with their chemical characters, including their atomic combining value, electrical character, and magnetic power. The diagram is quite startling in point of completeness, and certainly shows facts which must be explained by some, if not by the present, hypothesis.

Omitting many other most interesting and important points, we must notice the remarkable evidence obtained by Mr. CROOKES from his own laborious work in regard to the possible variation in the weights of atoms of the same element. Do all the atoms of calcium, for instance, weigh exactly forty, or is forty the average atomic weight, some atoms being as light as thirty-nine and some as heavy as forty-one? By a careful and long-continued system of fractionation Mr. CROOKES appears, at least in one case, to have separated, or as it were sifted, the lighter from the heavier atoms, getting thereby different elements, or, as we might rather call them, different elementary modifications

of the same element, quite as unlike one another as, say, nickel and cobalt. Whether this fractionation can be applied to other elements remains to be seen, but in the meantime it presents a working hypothesis, which may end by accounting for the almost though not quite identical atomic weights of some similar elements, and for many other peculiarities which at present are very puzzling. Whether confirmed or modified by subsequent researches, these observations and arguments certainly afford a splendid field for future work. The generalisations, put forward with the utmost scientific modesty, cannot be entirely untrue, although, of course, they may not give us an absolutely correct view of the whole truth as to elementary matter.

IT is impossible to read the published accounts of the last meeting of the Metropolitan Asylums Board without thinking of the lessons which Mr. JOHN MACDONALD teaches in an article he has contributed to the August number of the *Nineteenth Century*. Certainly it is true that "the life of the city, with all its variety of functions, should be like the life of the human organism, one and indivisible." The duties that have to be performed for the proper government of the community must differ widely from each other, but they all have as their object the promotion of the welfare of its inhabitants; and if the machinery which is used for this purpose is to produce the greatest amount of good, it must be guided by one mind which represents, and that directly, the will of the large majority of citizens. Just as one organ of the body has to perform one function and a different organ another, and health is only maintained when some controlling power is exercised which is in intimate communication with all, so, in the body politic, the various authorities which are created to minister to its well-being must be made to work in harmony by some central organisation which brings the work of each into common relation, and ensures that there shall be no friction and no waste of power in the efforts that are made.

Birmingham, we learn, was not many years ago governed by a number of parochial bodies, which all doubtless existed for the one purpose of bettering the condition of the inhabitants of the town; nevertheless, this end was not attained, for there was no bond which sufficiently united them. This want was at length supplied, and one body was created, elected directly from the people; and, as a result, a municipal spirit came into existence which has, in the course of comparatively few years, solved at any rate some of the most important problems of social life. Thousands of fever-haunted human piggeries, misnamed houses, have, we are told, been swept away. Birmingham has the control of her own police, her own gas, her own water, has built herself museums and free libraries; in short, with the exception of public education, the Corporation, representing in very thought the wishes of her citizens, has full power to deal with almost every subject that can reasonably be administered by a municipality. The local authority in consequence draws to itself men of the highest standing, all of whose actions are exposed to a public criticism that is the best safeguard of the public interests.

London is much in the position of Birmingham years ago. Divided into parishes, each with numerous boards having different functions, there is hardly one for which it can be said that it is an honour for the meanest of her citizens to belong. The actions of these bodies pass unobserved, unless some rare circumstance may for a while bring them under public notice. London has no control over police, gas, or water; even the boards whose jurisdiction extends over the whole metropolitan area can in no sense be said to represent the thoughts or wishes of the inhabitants. The Metropolitan Board of Works is but a vestry of vestrymen. The Metropolitan Asylums Board is but an enlarged board of guardians, with a sprinkling of members who are not even elected by the people whose money it is their duty to spend. The latter board cannot therefore altogether be held to represent the wishes of London, and every important step they take is the subject of objection by other bodies, who in their turn claim to represent local feeling and interests. Thus the recent determination of the Asylums Board to erect a permanent hospital at Darenth has been matter for protest by the various boards of guardians, and the Local Government Board have decided not to allow any but a temporary institution to be constructed. We can sympathise with this decision for the reason that it implies that the present method of small-pox hospital construction is not approved, and that no further hospitals of a permanent character will be erected in a manner similar to those which have been fully shown to be a cause of disease to the neighbourhoods in which they are placed; but this continual warfare between metropolitan local authorities is to be deplored. It is but too clear evidence of failure in metropolitan government.

London, it must be admitted, is not altogether comparable with Birmingham. Birmingham has but a tenth of the population of London, and the remedy that has been found successful for the smaller town might be less effectual if applied to the great city. Whether the difficulty is to be met by the constitution of one or of several municipal bodies, having control over the whole of London or of their respective smaller areas, is a matter for consideration.

IN a recent issue we drew attention to some of the leg[al] aspects connected with the supply to a town of a water containing sufficient lead to produce definite symptoms of lead-poisoning amongst its consumers, and we now revert to the same subject in its general and chemical aspects, in connexion with a highly interesting report that was some time back issued by Dr. SINCLAIR WHITE, medical officer of health, on the action of the Sheffield water on lead communication pipes, and its effects on the health of the community.

During the summer of 1885, Dr. SINCLAIR WHITE'S attention was drawn to several cases of chronic lead-poisoning in the borough, and it was observed that they not only occurred amongst persons whose trades did not expose them to any such result, but that the drinking-water to the houses in question in each case contained sufficient lead to account for the mischief. The Sheffield water, it would appear, is derived from two sources—namely, first, from the hills about Redmires; and, secondly, from hills around Strines and Agden; the two services being stored in different reservoirs, and being so delivered to the community that it was at once shown that it was the Redmires water which was alone doing mischief. All the mains in the borough

re of iron, and water drawn from these mains was found o be free from lead, whereas such Redmires water as had assed through the universally prevalent lead communication pipes was found to be contaminated; that which had tood in the pipes all night being most affected.

The gathering-grounds of the two services are in many espects similar, both being peaty, with shale containing ron pyrites and millstone grit beneath the surface. But he water from Redmires was found to be distinctly acid, he acidity varying in the several streamlets leading to the eservoir, but increasing very materially as the hill was scended, and being at its greatest where the water was ound to be lying in stagnant depressions on the surface of he peat. At Strines, however, the peat is less abundant, nd is drier; fine sand frequently comes to the surface, and owing to the configuration of the gathering-ground, there is ess tendency for the water to stagnate in pools.

The precise reasons why certain waters exercise a solvent power on lead, and this at times intermittently, are involved in some obscurity, and hence it is that special importance attaches to the record of the investigations made by Dr. WHITE to explain the occurrence in the case of the Sheffield water, and the special incidence of the mischief on the consumers of the Redmires water. In the first place, the source of the free acid is considered in connexion with the production in the atmosphere around Sheffield of sulphur dioxide by reason of the exceptional consumption of coal in the borough; but this is for various reasons set aside. One reason is that the reservoirs for the two services are practically adjacent, and yet only the water of one exhibited the acidity in question. Then, again, the oxidation of the iron pyrites in the gathering-ground would impart to the water free sulphuric acid. This view was, after consultation with eminent chemists, held by several authorities to be the actual cause; the iron pyrites, on exposure to moisture and oxygen, decomposing with the formation of free sulphuric acid. It is true that an insoluble sulphate of lead would be the result of the action of such a water on lead pipes; but, as is pointed out in the report, the insolubility of the lead sulphate is only relative, some waters taking it up in sufficient quantity to produce poisoning. Another view as to the source of the acidity is also entered into, and it is based on the fact that the decomposition of vegetable substances, such as wood, leaves, peat, and vegetable mould, gives rise to the formation of ulmic and humic acids. Now the Redmires gathering-ground is rich in organic matter, much of which is peat, and its configuration tends to the exposure of the water in pools to the influence of this peat; and not only so, but the Redmires gathering-ground differs from the Strines gathering-area precisely in those conditions which tend to favour the production of any such acids as those referred to. It must, however, be admitted that the collecting grounds at Strines are also more deficient in iron pyrites than those at Redmires, and that if the production of sulphuric acid from this substance is at the root of the mischief, the Redmires water would similarly suffer most. Unfortunately, the amount of free acid obtainable from the water was not sufficient to enable the borough analyst to determine its nature, or indeed to decide whether it was of organic or inorganic origin.

Whichever of the two latter views referred to in the report affords the correct interpretation of the occurrence, it should be remembered that summer weather, which was the period when the mischief first became obvious, would, by reason of the increased stagnation of water in pools during periods of drought, tend to increase the evil. It is quite possible that, since attention has now been definitely called to the occurrence, the existence of lead-poisoning by water in Sheffield may hereafter be found to account for symptoms which have hitherto been obscure in their origin, and that more attention will be given to the conditions favouring the process. But we trust that, even with waters collected from such a gathering-ground as that from which Sheffield draws its supply, nothing like a condition of permanency attaches to the water in this matter of lead solution, and that by careful investigation of the circumstances under which the facility for taking up lead increases or decreases we may come to learn something more as to the circumstances which enable such waters periodically to dissolve this substance. In the meantime Dr. WHITE has ascertained that the solvent action of the water upon lead is practically destroyed by keeping it in contact for a time with freshly broken surfaces of limestone, and that, even when the lead has been taken up many of the domestic filters in current use entirely remove it.

Annotations.

"Ne quid nimis."

THE BIRMINGHAM MEETING AND DIRECT REPRESENTATION.

THE number of candidates for the direct representation of the profession is growing day by day in a somewhat haphazard sort of way. It is clearly desirable that the profession should have a variety of candidates to choose from; but it is equally so that a candidate should come forward or be brought forward in a somewhat systematic manner. A committee should be organised for his election, and responsible officers should be named representing his committee. Less than this amount of trouble scarcely shows seriousness on the part of the candidate or a proper respect to the profession whose votes have to be secured. If the chances of success do not warrant this amount of trouble, it will be kind on the part of gentlemen not to complicate the difficulties of the profession by lengthening the list of candidates. The reasonableness of our suggestions will be more easily admitted if our readers will study the report we give elsewhere of what happened at a meeting in Birmingham. The promoters of that meeting were no doubt actuated by a laudable desire to assist the profession in choosing fit candidates. They were aware of a certain suspicion of cliquism, or caucusing, and took great pains to rise above all such charges and to make their meeting representative of the whole country. Dr. Carter said at the meeting that 343 responses had been received to 1167 invitations issued, representing 161 towns. But evidently 343 responses cannot represent 17,000 practitioners. And an actual meeting of only thirty-two is still more conclusive proof that the profession will have to show its mind in other ways. The supporters of any candidate will not be able to rely on any central or single meeting. Our profession is not organised for election purposes. Happily so! At the Birmingham meeting the first resolution seemed to commit the meeting to an immediate selection and requisition of three fit and proper persons. Nine or ten were nominated and a few were seconded. But by the time the

nomination was finished the meeting had become still more attenuated, and it was finally resolved to send the names nominated to members of the General Committee on a post-card, and to adopt those having the largest number of votes as the candidates of the committee. This course was approved by a majority of 11 to 3. We can scarcely doubt that the promoters of this meeting will be ready to admit its failure, and will not seriously prosecute their well-intentioned labours. They might take this comfort to themselves—that if they have failed no one committee is likely to succeed. About a dozen names are now before the profession in England in a more or less formal way, and it cannot be denied that at least half of these would make excellent representatives. The candidates are—Dr. Taaffe, of Brighton; Mr. Bullock, of Isleworth; Mr. Wheelhouse, of Leeds; Dr. Glover, of London; Sir Walter Foster, of Birmingham; Dr. Richardson, of London; Dr. Dolan, of Bradford; Mr. Hart, of London; Dr. Bridgwater, of Harrow; Dr. Holman, of Reigate; Dr. Balding, of Reigate; and Dr. Morris, of Spalding. The friends of these gentlemen, on local committees, and with proper confidence in their cause, will do what any one committee cannot do any more than any one Association. The profession, for the first time, feels itself with a "free hand," and it seems determined to use its freedom and to rebuke the fears of those who said it would be led in an undignified way.

RECENT DIARRHŒA MORTALITY IN LARGE ENGLISH TOWNS.

THE mean temperature of the fortnight ending Sept. 4th showed a marked increase upon that which prevailed in the preceding six weeks, and it is not surprising to find a considerable increase in the mortality from diarrhœa recently recorded in the largest English towns. The fatal cases of diarrhœa registered in the twenty-eight large towns dealt with in the Registrar-General's weekly return, which had increased from 530 to 710 in the preceding four weeks, further rose last week to 995, and considerably exceeded the number returned in any previous week of this summer. It is worthy of note that the mean temperature of the two weeks ending September 4th was almost identical with that of the fortnight ending July 10th, but that these two periods of high temperature appear to have affected the mortality from diarrhœa in London and in the large provincial towns in a very different manner. In London the earlier hot period caused a rapid increase in the deaths from diarrhœa from 43 in the last week of June to 411 in the last week in July, after which the weekly recorded deaths from this cause steadily declined to 176 in the week ending the 4th inst., this decline being apparently uninfluenced by the marked increase and excess of temperature during the fortnight ending on that day. In the twenty-seven provincial towns, on the other hand, having an aggregate population differing but slightly from that of Registration London, the deaths from diarrhœa increased from 43 in the last week of June to 804 in last week, the increase due to the first hot period being very small compared with that due to the more recent hot period. In the week ending July 31st, when the maximum diarrhœa mortality was reached in London, the annual death-rate from this cause was equal to 5·2 per 1000 in the metropolis, whereas in the aggregate of the twenty-seven provincial towns the mean rate did not exceed 2·5. The rate from the same cause last week, however, did not exceed 2·4 in London, whereas it was equal to 8·4 in the aggregate of the twenty-seven provincial towns. Epidemic diarrhœa mortality usually occurs in London before it attacks the provincial towns, although why this should be the case has not been determined. Neither is it easy to explain why the recent fortnight of hot weather has caused no increase in the diarrhœa death-rate in London, although it has produced such fatal results in so many of the large provincial towns. That temperature is not the only, or even the most powerful, factor in the causation of infantile diarrhœa may be fairly inferred from the following figures. The annual death-rate last week from diarrhœa, according to the Registrar-General's weekly return, ranged from 1·2 in Bristol, 1·8 in Huddersfield, and 2·4 in London, to 11·3 in Birmingham, 12·0 in Leicester, 12·4 in Preston, 12·8 in Hull, and 15·3 in Norwich.

CLINICAL EXAMINATIONS AND DANGER TO PATIENTS.

CLINICAL EXAMINATIONS on actual patients in hospital wards are, of course, of the utmost value in testing a student's ability to recognise and treat disease; but when, from whatever cause, they are so conducted that the patients suffer seriously from the processes to which they have been subjected, there is no doubt that some abuse of a very excellent system must have been permitted. A case has occurred in Brussels in which a surgical examiner, forming one of the central examination jury, while testing the candidates' knowledge in the Hospital of St. John, owing doubtless to some misunderstanding as to the nature of a case, removed an antiseptic dressing which had been personally applied with more than usual care by the visiting surgeon after an operation for suppurative inflammation of the right knee, so that when the patient was visited next day his condition was greatly changed for the worse, and subsequently the leg had to be amputated in order to save his life. The surgeon naturally reported the circumstances to the "Conseil des Hospices," the authority by which the Hospital of St. John is managed, and the consequence was that a regulation was made, ordering that during clinical examinations one of the medical officers in charge of the ward shall in future always be present. This regulation, which is asserted on the one hand to mean merely that examiners shall be informed what patients may, without injury to themselves, be made use of for examination purposes, and on the other to imply a desire to exercise some sort of surveillance over the proceedings of the jury, so offended the examiners that they decided not to hold any more clinical examinations in any of the institutions under the management of the "Conseil des Hospices," and betook themselves to the Hospital of Molenbeek St. Jean, which is under a different authority, and where the jury is "treated with the consideration which is due to it." The whole affair has been discussed pretty freely in Brussels, letters on the subject being published even in the daily press, and several somewhat contradictory accounts having appeared. The above is, however, we believe, a substantially correct statement of the facts. Considerable tension has unfortunately existed amongst the medical teachers in Brussels for some time past, and the incidents above related may possibly be to some extent due to that cause, and have of course had the effect of intensifying it. Surely some *modus vivendi* might easily be found which would enable our excellent *confrères* to compose their differences.

MASTICATION.

A CURIOUS controversy is in progress as to the need or value of "biting one's food." Strangely, as it must appear, there are some, who should be authorities, ready to affirm that it is futile to take the trouble to use the teeth with which nature has provided man in common with most other animals apparently for the special purpose of cutting and grinding his food. Little, if any, weight is attached to the evidence of facts in this dispute. The existence of the dental apparatus counts for nothing. Nor does it go for much that movements of the jaw promote the insalivation of the food. In short, mouth digestion is treated as a myth or

little better. What are we to understand by all this? Is it one of the early fruits of that attempt to popularise the science of physiology which has been so persistently and unselfishly made by the medical profession in the supposed interests of public health and the prevention of disease? We do not incline to mingle in the fray, just at present at least. Let the dispute go on and be fought out to the bitter end. Meanwhile, we counsel all who care for their comfort, and who do not desire to develop the worst form of dyspepsia, to continue the practice of mastication as before. As a matter of fact and experience, a liberal use of the teeth in feeding is one of the essentials of easy digestion, and though we are not prepared to assert that it is necessary to bite each morsel of meat precisely twenty-five times, it is better to err on the side of masticating too much than on that of not masticating enough: first, to divide the food and crush its fibres and particles generally, and secondly, to mix it so thoroughly with the secretion from the salivary glands that not only shall the act of deglutition be rendered easy, but that the food when it enters the stomach shall have been properly prepared for digestion in the gastric juice.

THE BACTERIOLOGY OF WATER AND AIR.

IT is well known that the atmosphere and water generally contain many forms of micro-organisms; but the conditions that are favourable to the growth of these low forms of life and the causes which lead to the development of toxic agents are a new field of investigation whose elucidation is a matter for future observation. Messrs. Crookes, Odling, and Tidy, in their official report on the persistence of bacterial life in water, have added to our store of facts so far as water is concerned. These observers have employed sterilised distilled water, in which a definite quantity (1 part in 150 of water) of peptone fluid, swarming with an active spireless growth of the splenic fever bacillus, was introduced. After the lapse of two hours an artificial cultivation of the infected water resulted in an abundant and characteristic growth of the bacillus, from which fresh cultivations could be produced. The results after the expiration of three hours were uncertain, and when a longer time had elapsed no cultivation could be obtained. The water used by the experimenters was of greater nitrogenous contamination than Thames water, and therefore highly suitable for the growth of the bacillus; and yet after the expiration of six hours the bacillus appeared to have effaced itself. On the atmospheric side of bacteriology, we have the observations of M. Miquel made on the air around Montsouris. An increase in the number of bacteria in the air was observed to accompany a rise in the barometric pressure and an augmentation also occurs in the summer months, though a sustained high temperature tends to lessen the number of bacteria. A low hygrometric state of the atmosphere was found to accompany the maximum number of bacteria, and a maximum number was also associated with a calm or slowly-travelling wind. The greatest number of maxima occurred with a north-east wind, and the least with a south-west wind. The presence of a large amount of ozone in the atmosphere went side by side with a reduced number of microbes. The observations at Montsouris have been carried on for a period of five years, and it has been estimated that the average numbers of organisms in a cubic metre of air, during spring, summer, autumn, and winter respectively, are 495, 650, 380, and 260. February gave the lowest average, 165, and July the highest, 700. The atmosphere of Paris is altogether different, for the average number of organisms in a cubic metre of air taken from the Rue de Rivoli was 3480, but the minimum and maximum occurred in February and July respectively, as at Montsouris. The number of organisms was very much lower in the year 1884 than in 1881, and this fact was associated with a greater efficiency in scavenging in 1884, and also with a lower death-rate from zymotic diseases. Dr. Miquel has also made a few observations on the atmosphere of London: only 240 bacteria being found in a cubic metre of air during the month of June. This comparative poverty of bacteria is attributed to the nearness of London to the sea and to the moderate height of the houses not preventing the purifying influence of the wind. What a tremendous contrast the atmosphere of the ocean and mountain presents with that of the wards of the Hôpital de la Pitié in Paris; for the former never contains more than an average of one bacterium per cubic metre, whilst the latter has been known to hold in suspension as many as 97,000 organisms in a cubic metre of air!

CHOLERA ON THE NEAPOLITAN RIVIERA.

ON this subject our correspondent in Rome writes:—The outbreak at Torre Annunziata is now describing the descent of the parabola, and the panic that was causing a general stampede from that lovely seaboard has died away. The significance of the visitation lies in the utter want of preparation on the part of the Neapolitan municipality for the spread of the disease from its latest outpost not ten miles off. When fugitives from Castellamare and Torre Annunziata and the other townships along the bay came trooping into Naples, *en route* if possible, to Rome and Tuscany, then only her sanitary authorities bestirred themselves, with the result of revealing to a scandalised public how little of the promised hygienic improvements had been effected. Two years ago, after the fearful explosion of cholera in the city, nothing was heard of but the immediate measures that were about to be taken for the clearing away of the rookeries, the amelioration of the drainage system, and the introduction of pure water. With the exception of this last, not one of these improvements, sanctioned by Parliament and expected by the country, has even been begun! The *Opinione* describes with bitter irony the feverish haste with which the Neapolitan sanitarians are turning out the court and cellar population into the street, often to contract other maladies than the expected one; flushing drains and whitewashing alleys, in the belief that the malady is as open to being scared as themselves! "To-day," it says, "all is activity, all is exaggeration; when the danger passes or diminishes there is the old relapse, with inertia, neglect, abuses." Doubtless, the plain-spoken journal, charged with salutary home truths, was duly delivered at the municipality, reeking of carbolic acid, although its point of departure was Rome, where well-timed precaution has long kept the enemy at bay!

"EXEAT BRUMMAGEM."

THAT scientists are fastidious and prone to hypercriticism is one of the fallacies of which little should be heard after the recent meeting of the British Association at Birmingham. Granting that the midland metropolis was at its best, that political differences were buried, and all the resources of the municipality and the people placed at the disposal of the learned visitors, these, irrespective of sex and section, were certainly in the most complimentary mood. The concluding meeting, held in the Town Hall, under the presidency of Sir William Dawson, was phenomenal, almost as much for thorough unanimity as for thronged attendance. The Mayor, Alderman Martineau—a lineal descendant of Martineau, the great Norwich surgeon,—with all his experience and tact, seemed positively embarrassed by the compliments showered upon him and his corporation by Professor Bonney and Capt. Douglas Galton. Sir Frederick Goldsmid and Dr.

Gladstone, F.R.S., were loud in praise of the financial success which the thousands of local associates had rendered possible; but it was reserved for Mr. Pengelly to utter a Pickwickian grumble. He had just before been wittily discussing in the Geological Section on a Scrobicularia bed containing human bones at Newton Abbot, but could not repress a feeling of disappointment. He had travelled thither in the belief that where they stood he should find "Brummagem." But he had not met with the article at all. The town buildings, the manufacturing exhibits in Bingley Hall, the educational institutions—nay, even the coffee, were intrinsically good and artistically fine. The bare fact is that very few communities have advanced at such rapid strides as Birmingham has done during the last few decades; and everyone interested in human progress may gratefully and hopefully say "Floreat Birmingham."

EVIDENCE OF INSANITY.

A GOOD rule of practice in regard to stating the ground of an opinion is to "never give reasons." There is great need of something approximating to this reserve in respect to the evidences which lead to the formation of a judgment that any particular person is insane. We do not for a moment doubt the fact that the hawker arraigned, and, in the event, convicted, before the Autumn Circuit Court of Judiciary for Forfarshire, for certain diabolical offences, was of unsound mind; but it must be confessed that the evidence adduced in support of the opinions formed by two excellent and most competent medical authorities was not only wholly inadequate but singularly inconclusive. Setting aside such presumptive evidence as the facts that his mother's father had been mad and had been put in a strait-waistcoat, that his mother's brother was silly and one of her own children had epileptic fits, and that the prisoner himself had suffered much in early life—as when he had scarlatina with delirium followed by deafness, whooping-cough of long duration, and a fall from a height of twelve feet on the back of his head, followed by unconsciousness for two days—the chief proofs of insanity seem to have been that he had a very imperfect notion of how the simplest accounts ought to be kept, that he could not count above twenty-nine, and that when asked his age, he said "nineteen or going in twenty," which, it was contended, was two ways of stating the same thing! There was no delusion, and nothing except a good deal of insensibility in regard to his crimes, which might either arise from a deficiency in the recognition of right and wrong or from anything else. Obviously, it could not be expected that a court of justice would be satisfied with evidence of this sort, when the plea of insanity was raised—not very wisely as it appeared—to shield from punishment a scoundrel who was alleged to have committed two rapes and other abominable offences against the person. We venture to think it would be more discreet in cases of this class, where the medical judgment of insanity is based on general and not on special grounds, to affirm the opinion without particularising reasons, rather than to bring forward evidence which is clearly not of a nature to be tested by unskilled jurors. We do not for a moment question the entire accuracy of the opinion expressed by the medical witnesses in this case. These gentlemen are so highly qualified to form a judgment on the issue raised that no member of the profession can hesitate to accept and adopt their opinions, but this fact only makes it the more regrettable that no better evidence should have been forthcoming in support of their views. In truth, it must often happen that good presentable proofs of insanity are wanting in cases where no room for doubt exists. The perception of disease is a distinctly medical function, whether the malady be one of body or mind. No sensible layman would expect a physician to adduce such evidence of the existence of what is called physical disease as would be available for the formation of a non-medical judgment. Why should laymen expect to be furnished with evidence of a nature to convince a person having no special knowledge of mental disease that it exists in any particular instance? It would be more rational and dignified if medical witnesses simply stated their opinions without giving reasons when requested to do so, and simply avowed their inability to place the grounds of a diagnosis before a lay court. In the course of a recent trial this side of the Tweed, a learned judge said, in reference to the evidence of an expert in caligraphy, that when once the indications discovered by the expert were pointed out, the unskilled observer was as competent as the expert to determine their value. We accept this ruling, but the indications of disease, whether of body or brain, are not of a nature to be thus brought under the cognisance of the unskilled observer. The medical witness is rather the "sworn interpreter" than the "expert" when he construes the evidences of disease and gives the result in a language "understanded of the people." If this were more generally recognised, there would be fewer experiences, in courts of justice, which are not merely disappointing but humiliating, and which it is most undesirable, on many accounts, to multiply.

TRAUMATIC PLEURISY.

DR. SEVED RIBBING reports, in the Swedish *Eira*, amongst a number of instructive cases, the following one of traumatic pleurisy. A man, who had received a blow on the right side of the thorax in a drunken quarrel, was admitted into the Cimbrishamn's Hospital with the ordinary signs of pleurisy with effusion. The cavity was consequently aspirated, the puncture being made in the eighth intercostal space just below the angle of the scapula. The signs of fluid returning, it was decided to open up the cavity. This was done by an incision in the same situation as that in which the aspiration had been performed, and a quantity of thick fibrino-purulent matter evacuated, a large French œsophageal sound being used for drainage. Two days after the operation it was noticed that the integuments and superficial muscular layer around the shoulder-joint flapped like a curtain at each inspiration. As this pointed to the existence of an abscess cavity communicating with the chest, a sinus was searched for and discovered running upwards from near where the opening into the thoracic cavity had been made. This sinus was laid open, and, together with the chest, carefully drained and washed out with carbolised water. The quantity of fluid which came away diminished daily; the temperature, which had been high, sank; and in three months' time the man was discharged cured.

VACCINATION IN EAST AFRICA.

A CORRESPONDENT, writing in *The Times* of Wednesday, quotes from a letter recently written in East Africa as follows: "The small-pox is very severe now in the Bondei Country. The natives are offering three dollars apiece to be vaccinated; but, most unfortunately, our lymph supply was destroyed in the late fire at Maglia. One man offered twelve dollars—i.e., nearly £2 10*s.* of our money. They have such faith in it, for none of the people who were thoroughly vaccinated have suffered at all from small-pox, while members of the same family who were not vaccinated were seized with it." It is the old story over again. When small-pox is prevalent in an unvaccinated community, vaccination is valued, and no complaint is heard other than that which is caused by the scarcity of lymph; but when a community is more or less protected by vaccination from death by small-pox, then its value is forgotten, and the agitators of the time assert themselves very loudly. There is little doubt

that if, instead of a compulsory law, difficulties had been put in the way of vaccination, the same individuals who now describe vaccination as a "huge and deplorable delusion," would have been loud in their demand for a removal of the restrictions. But these agitators must forgive our statesmen if they refuse to submit the country to a wholesale destruction of human life for the purpose of teaching them the lesson they need to learn.

DIAPHRAGMATIC HERNIA.

Il Bullettino della Reale Accademia Medica di Roma (May, 1886, p. 245) contains a description by Dr. Ferraresi of a diaphragmatic hernia revealed in the necropsy of a young man who had died with symptoms of intestinal strangulation. On surface inspection of the well-nourished body, it was noted that the abdomen was only slightly swollen; the left half of the thorax was broader and more prominent than the right, and the left intercostal spaces dilated. Percussion revealed an area of absolute dulness over the whole left chest, excepting the subclavicular triangle, which yielded tympanic resonance. On opening the abdominal cavity, the coils of small intestine, slightly reddened, presented patches of fine basal injection. Carefully opening the thorax, the left pleural cavity was found filled with a bloody liquid, on giving exit to which the lung, compressed and driven upwards, became visible, the heart being displaced to the right. Besides the liquid already referred to, the pleuritic cavity contained numerous coils of intestine enormously distended, of dull red colour; the serous membrane was opaque, rough, and studded with numerous hæmorrhagic spots. The stomach was displaced to the right, with the great curvature turned towards the abdominal wall. Holding aside the stomach and the small intestines, still retained in the abdomen, it was observed that the splenic angle of the colon and a good part of the jejunum passed into the pleural cavity through a hole in the left inferior half of the diaphragm at a point corresponding to the normal position of the heart's apex. The descending colon was much contracted. With great difficulty, and after repeated punctures, it became possible to reduce the coil of colon, a piece of omentum, and the displaced small intestine. The hole in the diaphragm was oval, rather more than an inch in diameter, surrounded by a strong, thick, fibrous ring. The gastro-colic omentum which followed the displaced coil was shortened, and adherent posteriorly to the margin of the fibrous ring.

THE INFLUENCE OF SMALL-POX HOSPITALS.

ON Saturday last Mr. Justice Stirling heard, in the High Court of Justice, an application on behalf of a dairyman living at New Windsor for an injunction to restrain the Mayor and Council of New Windsor and the guardians of Windsor from erecting hospital tents for small-pox patients on certain meadows in proximity to his dwelling. The case presented but little medical interest, the proceedings apparently being taken in anticipation of the extended use of a temporary hospital which had been erected on the site. The medical evidence for the plaintiff, it seems, did not go beyond placing before the Court the information contained in recent reports of the Medical Officer of the Local Government Board, which pointed out the effects of aggregation even of a small number of patients suffering from small-pox in its acute stage, and showing that the hospital was not constructed in the manner suggested by the Royal Commission, so as to ensure the destruction or purification of the air in the wards. The hospital subsequently did not receive more than seven cases, and the site not being found suited for hospital purposes, it was determined to abandon it and receive no more patients into the institution. Under these circumstances Mr. Justice Stirling refused the application. The case is instructive as showing that, if local authorities determine to erect hospitals for this purpose near inhabited houses, they will probably meet with opposition, unless they construct them in the manner indicated, or limit their use to a very small number of cases.

MANAGEMENT OF THE THIRD STAGE OF LABOUR.

DR. A. R. FISHER, assistant in the obstetric clinic of Professor Slavianski in Kharkoff, has made a large number of observations with the view of determining the relative advantages in the third stage of labour of Credé's system of gentle manipulation or massage of the uterus, and the method of forcible expression of the placenta by powerful compression of the uterus. His statistics point decidedly in favour of the former method. In 493 cases where Credé's method was employed post-partum hæmorrhage occurred twenty-five times, while in 183 cases where expression was resorted to it also occurred twenty-five times; that is to say, the hæmorrhage cases were 5 per cent. with Credé's method, and 13 per cent. with the expression method. Again, the retention of pieces of membrane occurred less frequently with the former than with the latter mode of treatment, the percentage of cases in which this occurred being 5·7 and 7·4 respectively. The relative proportions of the occurrence of pyrexia, by which was understood any rise above 38° C., the temperature being taken three times daily, were 38·3 per cent. and 46·4 per cent., and the cases in which puerperal complications supervened were also fewer after Credé's method than after the more violent procedure, being respectively 5 per cent. and 9 per cent. A diagram is given with the author's paper, which is published in the *Russkaya Meditsina* of August 10th, showing that the process of the involution of the uterus is perceptibly quicker, at all events during the first week, in cases where Credé's method has been used, than in those where the placenta has been expressed. Dr. Fisher concludes with a general eulogy of Credé's method, as being the most rational and successful plan of treating the third stage of labour, and withal so simple that every doctor, and indeed every properly instructed midwife, should practise it habitually.

LARYNGEAL PARALYSIS IN LOCOMOTOR ATAXY.

AN interesting case of locomotor ataxy was recently in the Birmingham General Hospital, under the care of Dr. Robert Saundby. The patient, in addition to the ordinary symptoms of the disease—e.g., ataxic gait, loss of patellar reflexes, inability to stand with his eyes shut, &c.,—complained that he could not lie down in bed on account of difficulty of breathing. When he was induced to assume a horizontal position, he was seized with an alarming suffocative spasm. His voice was a little hoarse, but otherwise normal. On laryngoscopic examination, both cords could be seen lying in the middle line in the position of phonation, no motion being perceptible on inspiration. The movements on phonation were normal. A few days later a very severe attack of dyspnœa almost proved fatal, and tracheotomy, which had previously been advised but declined, was performed at once. The man died a few hours afterwards in a fit of coughing, a large amount of pus welling up into the trachea. As permission could only be obtained for a partial necropsy, the head could not be opened. The spinal cord showed well-marked sclerosis of the posterior columns. Cases of this kind are rare, but examples have been recorded by Dreschfeld, Semon, and Charcot. Dr. Saundby remarked that such cases possibly occur more frequently than records

of them might lead one to suppose, and that in all cases of bilateral paralysis of the abductors of the larynx other signs of locomotor ataxy should be sought for; conversely, all cases of the latter disease should be examined with the laryngoscope, as it is only when the paralysis is complete that urgent symptoms are present as they were in the case under notice.

LUNACY LAW REFORM.

THE objections taken to the vote for the Lunacy Commission in England were well grounded. The authority at Whitehall is not worth a tithe of the money devoted to its maintenance. The existence of a body bearing the name of a Commission is doubtless of some moral weight, and for this the public may be willing to pay a small sum. We will go further, and admit that as the labourer is worthy of his hire, without regard to the real value of his services, the gentlemen who hold office, whether as legal or medical commissioners, are entitled to their stipends; but for all the good actually done by the Commissioners in Lunacy, a couple of clerks at £500 a year, to register the certificates sent in if the forms be properly filled up, or to return them for correction if irregular, would be as fully effective as the whole staff maintained at a cost to the taxpayers of £15,000 yearly. The Government announces another Lunacy Bill. We do not at the moment remember how many Bills have been introduced during the last ten years, but the number must be considerable. Will the now promised measure be any better than its predecessors? We think not. The subject is so thoroughly in the hands of the red-tapists that there is absolutely no reasonable ground for hoping that a satisfactory measure will be introduced. Nothing short of a complete reconstruction of the law relating to the sequestration of lunatics, placing the treatment of insanity entirely on the footing of a medical care and cure of the insane, and safeguarding the liberty of the subject by taking the right of incarceration wholly out of the hands of private persons, can be satisfactory; and so large a measure of reform as these changes would involve we fear there is not the slightest reason to anticipate.

THE ELECTRIC LIGHT AND THE EYE.

PROFESSOR COHN, whose works on the Hygiene of the Eye are so well known, has lately delivered a lecture in Breslau upon the Action of the Electric Light upon the Eye. That this light sometimes induces inflammation both of the internal and external tunics, when incautiously used, is indubitable. Cases have occurred in which retinal inflammation and sclerotic congestion have followed protracted exposure to arc lights, and this arises in all probability from the great concentration of the light of such burners, the field of vision otherwise being dark, a condition that is very different from that of diffuse daylight, which we know to be free from danger, though the light is certainly as intense, whilst the field generally is much more perfectly illuminated. Professor Cohn remarks that artificial light should not be dazzling, that it should be supplied bountifully; it should not heat the eyes, and it should burn steadily. Arc lights, he thinks, in order to fulfil the first condition, should be surrounded by a globe of white or ground glass, which deprives it, however, of about 30 per cent. of its illuminating power. Even with this diminution its penetrating power is greater than gas of equal brightness, because the same quantity of light is concentrated in a smaller space. According to the investigations of Voit and Ranke, at Munich, the light from a glow lamp of Edison is seven times brighter than that of an Argand gas lamp, and twelve times brighter than that of a fan-shaped gas light. The glow light will therefore excite the retina from seven to twelve times more than a gas flame of equal brightness. If the electric light be used, care should be taken that it is not too weak, for in that case books or work must be held close to the eye, and there is abundant evidence to show that such approximation is a fertile source of short-sightedness. Professor Junge of Zurich informed Professor Cohn that the local reading society had given up the use of the glow-lamps because with the power supplied the illumination was too weak. To obtain a sufficient light in this instance a dynamo of double the existing power would have had to be erected, and the expense then would have been double that of the gas. The absence of heat is a great point in favour of electric lighting, for a hot flame in proximity with the eye dries up the moisture on the cornea, and, after producing a feeling of dryness, is almost certain to lead to congestion of the vessels which surround it, and to pain and headache. Professor Cohn himself demonstrated some time ago that the rise of temperature 8 in. from a gas flame is double that at the same distance from a glow lamp of equal brightness. Additional advantages which are possessed by the electric light are the absence of carbonic acid gas and other products of combustion. The examination of the air of theatres in which gas is burnt with that of theatres which are illuminated by electricity shows in the latter less carbonic acid and no smoke, and that the quantity of moisture added is much less, whilst the temperature is lower. The Professor points out the importance of the electric light being steady. When a flame flickers the intensity of the light is undergoing constant change—a condition to which the retina is very sensitive, as is shown by the disagreeable sensation felt in walking along an open wooden railing on the other side of which the sun is shining. On this ground the glow-lamp is superior to the arc light. In either case the strength of the current should be sufficient to make the light steady and strong.

CLINICAL TEACHING AT MELBOURNE.

WE learn from the *Melbourne Argus* that on July 22nd the Premier received a deputation of students of the Medical School, who had taken this unusual but legitimate course of urging on the Government to insist that out of the grant made to the Melbourne University the sum of £500 should be applied to the appointment of clinical lecturers. Mr. Gillies said that at the request of the students he had invited some members of the University council to attend, and they had forwarded him a resolution to the effect that it would not conduce to the discipline of the University for the council to meet their own undergraduates and argue with them in public on the course the council had thought it necessary to pursue. Mr. Gillies could not take any exception to this resolution; he would hear what the students had to say, and would afterwards communicate with the council. Mr. C. P. W. Dyring, B.A., read a statement prepared by the committee of the Medical Students' Society, which dealt with the importance of adequate clinical teaching and the necessity for it, every examining body requiring certificates of attendance on such lectures. The University authorities required this, and the rules of the Melbourne Hospital provided for the appointment of special clinical lecturers by the council of the University from among the members of the medical and surgical staff. In 1883 a deputation from the council applied for an increased endowment, specifying among the immediate requirements "two clinical lecturers, medicine and surgery, £500." Parliament voted an increase of the grant by £2000, and the University calendar of 1884-85 showed that the council recognised that the sum of £500 was voted specifically for the payment of clinical lecturers, who were appointed in 1884; but in the following year the council departed from this system. No clinical lecturers were appointed for the current year, and the

chancellor had stated that neither the sum of £500 nor any other sum was expressly granted for the purpose. This relinquishment by the council of control over clinical teaching elicited a protest from the Faculty of Medicine, and left the students without systematic training, and only such instruction as they could gather during the ordinary visits of the medical staff at the Melbourne Hospital. It was felt that when this became known in Great Britain, the recognition hitherto accorded to their courses of instruction would be discontinued, and already evidence had been received of this from London and Edinburgh, where instances had occurred of the inability of students to obtain certificates of attendance on clinical lectures on surgery and medicine, although they had attended hospital practice &c. in the Melbourne School. While one-half the fees received by the University from students were paid to the Medical School, only one-ninth of the Government grant was devoted to the purposes of that school. Messrs. Goodall and Ick, M.A., and Prof. Pearson also advocated the claims of the students, and Mr. Gillies promised to communicate with the council, and had no doubt the difficulty would be easily overcome. By this time, we trust, the matter has been arranged. It is incredible that a University like that of Melbourne should be without professors of clinical medicine and surgery, not to speak of the hardship inflicted upon the students who, desiring to qualify in Great Britain, find that their course of study at Melbourne has been incomplete.

THE KASHMIR MISSION HOSPITAL.

SINCE the erection of the Mission Hospital in Kashmir in 1875, a large amount of medical and surgical work has been carried on there by the medical missionaries successively in charge of it—Drs. Maxwell, Downes, and Neve; indeed a good deal of what may be called original work and observation has been done, as the various papers which have appeared in our columns from time to time will show. The report for last year has just reached us, and testifies to much suffering relieved by highly scientific methods, Dr. Neve's aspirations being of a commendably high order, for "no surgeon," he says, "is doing his duty who aims at anything less than the best possible result for each individual case." Most of the in-patients, of whom there were 641, were surgical cases. Of 1010 operations that have been performed, 351 rank as major according to the Indian Government classification. The mortality from operations was certainly low, there being only five deaths in all—four from shock, one from tetanus. Dr. Neve considers the practice of antiseptic surgery emphatically economical, as well in diet as in trouble of dressing, to say nothing of its power of saving life and limb.

TRICOCEPHALUS DISPAR AND BERI-BERI.

DR. H. ERNI, of Batavia, writes (*Berlin Klin. Woch.*, No. 37) in support of a doctrine that beri-beri is a secondary anæmia due to the loss of blood produced by such intestinal parasites as ankylostomum duodenale, tricocephalus dispar, and a peculiar dipterous larva. Perhaps the chief interest of his communication is in reference to the tricocephalus, which was far more frequently found in the intestines of subjects of beri-beri than any other parasite; but one or other of the above was rarely present in more than fifty cases examined, whilst they were rarely found in other diseases. Of course, those who contend that beri-beri is an epidemic poly-neuritis, from the evidence of peripheral nerve degeneration, would be disinclined to attribute any share to the presence of such parasites; but similar degeneration to that of the nerves attacks the muscles and other tissues, and may well be ascribed to the chronic anæmia which is the leading symptom. The tricocephalus inhabits the cæcum, and may occur in large numbers. In the slighter cases there is localised inflammation of the cæcum and neighbouring parts of the colon; in others there are definite erosions and points of hæmorrhage which have been produced by the worm; whilst in others, again, the mucous membrane is even undermined by the parasite. Hence the cases are characterised more or less by intense symptoms of enteritis. The obvious criticism upon the thesis of Dr. Erni is that the tricocephalus is a very common parasite in Europe (in Paris it has been stated that one-half the population is infested by it), and that it has never been hitherto assigned so serious a *rôle* as that which he awards it; unlike the ankylostomum, which has been fully proved to be the cause of fatal anæmia as exhibited in the St. Gothard miners and in Egyptian chlorosis. It is hardly conceivable that a parasite which is harmless in Europe should be capable of producing such grave intestinal lesions in the East Indies; for although under the term "beri-beri" doubtless many varieties of purely secondary anæmia may be included—comprising, we are willing to believe, cases of "ankylostomiasis,"—yet more evidence must be forthcoming before the tricocephalus is accepted as a prime etiological agent in the affection.

PUBLIC HEALTH IN PENNSYLVANIA.

THE State Board of Health have submitted to the various cities and boroughs within their jurisdiction a model ordinance for the better preservation of public health, together with a recommendation that its provisions should be adopted with such modifications or additions as may be found needful in special localities. The plan adopted is much the same as that which has been followed by such excellent results from the issue by the Local Government Board in this country of its series of model bye-laws dealing with sixteen separate subjects. Whilst, however, our own codes are much more detailed and comprehensive than that issued in Pennsylvania, the latter deals with some subjects which in this country are dealt with by special statute. Thus, facilities being given for gratuitous vaccination, a section is inserted to the effect that "no pupil shall be allowed to attend the public schools ..... who has not been vaccinated successfully within seven years." In this, and in similar ways, vaccination, which is made directly compulsory in this country, becomes indirectly so in several of the American States.

CHOLERA INTELLIGENCE.

THE cholera intelligence for the fortnight ending Sept. 14th involves several points of importance. In the first place, whilst there has been no general increase in the amount of cholera in Italy, yet the disease has shown itself in several newly invaded places with considerable virulence. Thus, at San Marco in Lamis, there have been 109 more deaths, and at Torre del Annunciata 83 deaths have taken place; the outbreak in this latter place being the most prominent feature of the extension of the epidemic to the Bay of Naples, where Castelamare has also been fatally affected. Five cases have also occurred in Naples itself, but it is believed that these have all been immigrants from other affected localities. Putignano and Taranto are two other freshly invaded districts in Southern Italy, 68 and 8 deaths respectively having occurred in these places during the period in question. The disease also clings with considerable tenacity to several of the towns and provinces in the north-east of the kingdom. From Sept. 1st to the 14th there were 59 deaths in Ravenna, 26 at Padua, and 65 at Ferrara. In all, the records published for the fortnight give 528 fatal attacks in Italy, and this although, as regards several places, there are blanks in the returns which make them very incomplete.

It has also been announced that cholera during the present year has attacked 45,000 persons in Italy, and that of these 14,000 have died. For several days there have been rumours of an increase of cholera in the neighbourhood of Trieste, and of the extension of the disease to Pesth, and it is now announced that on the 12th inst. twenty cases and eight deaths occurred from cholera in the latter city. The disease is also stated to be rapidly spreading in Croatia, where isolated cases have for some time past occurred. Perhaps the most important consideration involved in this news from the Austro-Hungarian Empire lies in the fact that cholera is invading entirely new territory. This must materially affect the prospects for next year. It had been hoped that the disease, especially as seen in North-eastern Italy, indicated the termination of the epidemic of 1884-86, but this fresh extension may perhaps come to be the first sign of a probable prolongation of the visitation into 1887. From this point of view cholera in Hungary has especial interest.

MECHANICAL REMOVAL OF CROUPOUS EXUDATION AFTER TRACHEOTOMY.

AFTER tracheotomy for croup, when it is found impossible to clear the trachea from membrane by forced expirations, suction, &c., Dr. Pievigzók, writing in the *Przeglad Lekarski*, advises the use of Schrötter's forceps, which, he says, should be so introduced through the wound that the blades may open antero-posteriorly, and not laterally, for fear of taking up the angle at the bifurcation of the bronchi. Sometimes it is possible completely to clear the trachea by one or two introductions of the forceps. In cases where the obstruction is in one of the bronchi, the patient should be laid on the corresponding side and the forceps inclined accordingly. Information may also be obtained as to the situation of the obstruction by the aid of a mirror introduced into the wound, the patient's head being at the same time thrown well back. The instrument which the author finds most suitable for this purpose is Zanfal's nasal speculum. He remarks that children bear the operation without any special trouble.

AN UNOFFICIAL PHARMACOPŒIA.

AT the meeting of the British Pharmaceutical Conference held at Birmingham last week, the President, Mr. Thomas Greenish, in his inaugural address, referred at some length to the present unsatisfactory condition of the art of pharmacy. He stated that the British Pharmacopœia in no way represented the advance which had been made in their department of science in the long interval which had elapsed between its publication and the preceding issue. It was simply a collection of fragmentary papers, with [illegible] absence of the applied practical knowledge necessary [illegible] the proper elaboration of such a work. The result had be[illegible] most unfortunate, and, excepting in some of the large ce[illegible] and more important provincial towns, pharmacy he[illegible] existence for pharmacists, the whole of the work [illegible] absorbed by medical men, to the detriment of the in[illegible] of those whose legitimate calling it was supposed [illegible] Prescriptions were now so rare that, when one ma[illegible] appearance once a fortnight or thereabouts, the[illegible] quite an excitement to see the curious interru[illegible] their ordinary duties. There was a growing [illegible] might be called "wholesale prescribing for [illegible] cal profession." Proprietary preparations, for [illegible] part "factory made," were thrust upon docto[illegible] blushingly advertised, sapping the foundations [illegible] and depriving the pharmacist of the legitim[illegible] of his calling. Chemists were harassed by [illegible] for these proprietary medicines, which pr[illegible] up without thought, and without a second thought thrust aside. It should be the business of the Conference, as soon as unofficial preparations of a certain type attained favour with the profession, to construct formulæ fairly representing them, and issue them as unofficial formulæ, which might be prescribed by medical men with the addition of the letters "B.P.C." or British Pharmaceutical Conference. At the conclusion of the address, it was resolved—"That in order to secure greater uniformity of composition and strength in non-official remedies, and also to enable the medical profession to prescribe them with definite knowledge of those qualities and without indicating any particular maker, the British Pharmaceutical Conference undertakes the preparation of a formulary of non-official remedies." With the view of giving the resolution effect, a committee was appointed with instructions to enter on its labours at once, a grant of money being placed at its disposal for expenses. The *Chemist and Druggist*, commenting on the President's address, points out that an article is not necessarily bad because it is "factory made," and that there is no special reason why proprietors of such articles should be expected to blush when they advertise them. True pharmacy is not a religion hedged about by dogmas never to be changed or challenged without calling forth a charge of impiety, but simply a business free to all with certain qualifications, and requiring vigour and intelligence for its successful prosecution. The doctors who first ordered small bottles of concentrated medicines—"ten drops to be taken in a wineglassful of water"—did a great deal towards sapping the foundations of the true pharmacy of fifty years ago, but chemists and druggists had to adapt themselves to the change.

HYDROPHOBIA.

OUR Paris correspondent writes:—"The following case of authenticated cure of hydrophobia addressed to Dr. de Pietra Santa, and which was published in the *Journal d'Hygiene*, may be of interest. A peasant of Saint Anastasia, near Naples, aged fifty-two, was bitten on the 10th of May last in the leg and in the forearm by a dog whose rabid condition was verified at the necropsy. On July 28th the man was suddenly seized with malaise, excitement, and oppressed breathing, accompanied with a sense of constriction in the throat. His wife offered him a glass of water, but the sight of this liquid immediately threw him into a fit of [illegible] reso[illegible] convulsions. He was not condu[illegible] the discipline [illegible] Incurables at Naples, whe[illegible] taken to their own und[illegible] with [illegible] he was admitted [illegible] ward of Dr. de Capua in a [illegible] deplorable condition. The patient complained of feeling cold; the sight of water and the slightest current of air provoked a great degree of excitement, convulsions, and delirium. Basing his faith on the eminently parasiticidal virtue of corrosive sublimate, Dr. de Capua immediately practised repeated injections of this salt subcutaneously, and combated at the same time the nervous paroxysms (culminating symptoms of rabies) with injections of atropine, which he alternated with those of the corrosive sublimate. The injections were renewed the following days. This treatment was crowned with full success. The rabic symptoms amended progressively, and after a few days the patient was able to swallow a glass of water without wincing. Soon after this he asked to eat and drink, and expressed a desire to leave the hospital. Dr. de Capua observes that the delirium in this case assumed three distinct forms, which followed one after the other. In the first place it was mournful and melancholic; the patient believed himself to be the object of all kinds of persecution. This was succeeded by a delirium bearing a relation to his profession: he imagined that he was occupied at his village with his usual agricultural pursuits.

Then came the mystic form, manifesting itself by prayers and religious hymns from morning till night. Dr. Macario, of Nice, the author of this paper, concludes it with the recommendation that physicians and physiologists should undertake experiments, either to confirm or disprove the therapeutic value of corrosive sublimate and of atropine against rabies, adding that if clinical observation and experimental tests on animals confirm the efficacy of the medication proposed by the Neapolitan physician, we shall have at our disposal two powerful arms to combat the most terrible of maladies—the anti-rabic inoculations of Pasteur as a prophylactic means, and the subcutaneous injections of corrosive sublimate and atropine of Dr. de Capua as a curative measure. This will be one of the most marvellous conquests of modern medical science."

SCARLATINA.

THE *Birmingham Medical Review* contains a contribution to the pathological anatomy and histology of scarlatina by Dr. Crooke. It is remarkable that the mammilated appearance of the pyloric region of the stomach was very marked in a case that terminated fatally in twenty-six hours. Microscopical examination showed that this appearance was due to inflammatory hyperplasia of the adenoid tissue, which is normally present in the gastric mucous membrane of children and young adults, as Dr. Herbert Watney has demonstrated. At some places the hyperplasia is seen to be so considerable as to extend up to the surface of the mucous membrane, displacing in its extension the gastric tubules. Whilst able to corroborate the accuracy of the observations of Dr. S. Fenwick as to the presence of interstitial gastritis in scarlatina, Dr. Crooke does not regard the interstitial change as evidence of a past morbid process. He believes that simple catarrhal gastritis occurs in a more or less marked degree in most cases of scarlatina, fatal during the febrile stage; but that in cases characterised by the exceptional severity of the gastric disturbance, where the interstitial changes are so pronounced as in three cases examined by him, the condition is usually, if not invariably associated with a similar acute interstitial and follicular inflammation of the mucous membrane of the intestine, and is therefore to be regarded as part of an acute inflammatory attack, of which the chief stress falls on the adenoid tissue of the stomach and intestines.

THE ROYAL BELGIAN SOCIETY OF PUBLIC MEDICINE.

THE Belgian Society of Public Medicine has just held its annual meeting, which was attended by a large number of persons. M. H. Kuborn presided. The main question discussed was, "the removal of excrementitious matter from towns and thickly inhabited localities unprovided with sewers." In the report, which was adopted after a lengthened discussion, a strong condemnation is expressed of cesspits (*puits perdus*), and an opinion hazarded that they should be forbidden by law. The system of separating solid and liquid sewage is also condemned, as are all the known methods of disinfection, which, it is remarked, are expensive and frequently destructive of the fertilising properties of the sewage. Deodorisation processes are admitted to be valuable in certain cases only, as in camps, hospitals, and isolated barracks or houses. The system of cesspools and movable receptacles (*fosses mobiles*) may be permitted under strict surveillance, but a regular system of sewage acting by gravitation or worked by pumps is much better from a hygienic point of view than any other; this system should be water-tight, and should convey sewage of all kinds to one or more central reservoirs. The question, therefore, which the Society had to discuss seems to have been somewhat shirked, for the reply is virtually, "If there is no system of sewers in existence, the only thing to do is to construct one." It is to be hoped, too, that the omission of all mention of sewer ventilation in the report does not imply that that is considered an unnecessary precaution.

DISEASE OF THE NOSE CAUSING APHONIA AND DYSPNŒA.

DR. PREDNORSKI mentions in the Polish journal *Gazeta Lekarska* a case of aphonia and spasmodic dyspnœa, where the cause was found to be an affection of the nose. A young Jewess, subject from childhood to attacks of epistaxis, received a severe nervous shock, being, in fact, the subject of an attempted violation. After this she completely lost the power of speech and began to suffer from attacks of spasmodic dyspnœa; her catamenia also ceased. One of the attacks was so alarming that it was thought that tracheotomy would have to be performed, and preparations were made for the operation, but, on chloroform being given, her condition improved so much that she not only breathed more easily but began to scream, so that all thought of operative procedures was abandoned. In a few weeks' time the girl seemed much better, but subsequently the symptoms reappeared. The nose, on examination, showed that the lower and middle turbinated bones on the left side were red and tumefied. When they were touched pain was produced, accompanied by sneezing and discharge of mucus. The application of chromic acid quickly and completely restored the patient to her usual state of health.

THE MASSACRE OF THE INNOCENTS.

A CASE of poisoning which serves forcibly to illustrate the necessity for caution in the administration of opiates to children has recently occurred at Goole, and has been the subject of an investigation by Dr. Grabham, the coroner for the Honour of Pontefract. From the evidence of the mother, it appears that her child, aged nine weeks, having been cross all day, she sent the servant girl to the chemist for a pennyworth of Godfrey's cordial, giving her an old bottle labled "Poison" to fetch it in. She noticed a brown coating at the bottom, but did not take the trouble to wash it out. When the girl returned, she took the bottle off the sideboard and gave the baby a teaspoonful. She then found she had made a mistake, and shortly after the child died. The servant stated in evidence that she misunderstood her mistress and asked the chemist for a pennyworth of laudanum. When she came back she was sent out again directly, and put the bottle down on the sideboard, and that was how it happened. The chemist deposed that he did not recollect the last witness coming to his shop, as so many people came for laudanum, and he sold pints of it in the course of the week. The coroner, in summing up, said the cause of death was clear. The mother admitted that she had given the child a teaspoonful out of the bottle, whilst the servant told them that she had asked for laudanum instead of Godfrey's cordial. He did not blame her, for she was young and thoughtless, and had only been entrusted with a verbal message to get a pennyworth of the cordial, which she had translated into laudanum on her way to the shop. Even if she had not made the mistake, there was probably enough dried laudanum at the bottom of the bottle to have caused the child's death. He could not blame the chemist, for he was within the law in selling laudanum without asking what it was for, the Act of Parliament simply requiring that a poison label should be placed on the bottle. It was startling to be told by the witness that every week he sold pints of laudanum to his customers, for it could not be supposed

that even a fraction of this was required for external application. The existing law regulating the sale of poisons was to blame, and he trusted the Government would soon take steps to remove this blot from the statute-book. Steps should be taken to protect both infant and adult life, for the number of people killed every year by opium, whether sold as such or in the form of quack nostrums, was frightful to contemplate. Opium in any form was a dangerous poison to young children, and should never be administered to them without the advice or under the superintendence of a medical man. The jury returned a verdict of "Death by misadventure." At an inquest held a few days ago at Kensal-green, Dr. Diplock, the coroner, told the jurymen that they "would be astonished if they knew the number of deaths through parents taking their children to chemists, and thus losing time in the proper treatment of disease." The necessity for legislation in the direction of the better protection of infant life is apparent.

INTESTINAL LESIONS DUE TO CORROSIVE SUBLIMATE.

THE use of the corrosive sublimate in general antiseptic surgery has led MM. Charrin and G. H. Roger to investigate the intestinal conditions said to be caused by the absorption of the salts of mercury. Although there can be no doubt of the capacity of mercurial salts absorbed into the blood to produce serious changes in the intestines, yet it has been questioned whether the solutions ordinarily employed are capable of causing the intestinal lesions which have been attributed to their action. It must always be remembered that in the cases in question the chance that the intestinal lesion may have been caused by the disease from which the patient is suffering always exists. The experimenters above mentioned have injected under the skin and into the veins of rabbits and guinea-pigs a solution of 1 in 1000 and 1 in 4000 of corrosive sublimate. Administration by the mouth has not been practised, because Prevost has shown that quantities ten times as large as those injected hypodermically would be required to produce the same effects. It has been found that a medium dose injected at a single time had more effect than a much larger dose administered over a longer period. Thus, to a guinea-pig weighing 500 grammes, two milligrammes injected at once under the skin may determine the formation of numerous ulcers, whilst five milligrammes given in eighteen days, or three in six days, produced no effect. The animals experimented upon have rarely shown special indications of intestinal lesions; emaciation and albuminuria frequently occurred, but rarely diarrhœa, and never intestinal hæmorrhage. Small doses only being administered, the animals have never died, but have been killed at different periods in order to follow the evolution of the intestinal changes. The lesions have always been confined to the large intestine, and chiefly to the ascending colon and cæcum. In some cases the ileo-cæcal valve was attacked, and occasionally the lower part of the ileum. The essential nature of the changes appears to be a hæmorrhage, which first of all takes the form of minute points; these gradually increase in size until areas of extravasated blood are formed, which may undergo a kind of sloughing, the varying degrees of extravasation being in direct proportion to the amount of the poisoning. Inflammation may take place around the extravasations, but perforation has never been observed. To transfer these facts to the domain of human pathology, it would appear that a single dose of ·24 gramme (or ·60 gramme spread over five days) would be required in order to produce the intestinal lesions always assuming, what we have but little right to do without actual observations to support the supposition, that the susceptibility of men to the poison is the same as that of the animals experimented upon. It is not impossible that the intestinal lesions in man may be induced by very small doses of the sublimate.

COLD BATHING.

THE use of cold water as a bath for ordinary health purposes—we are not speaking of its use for the strictly medical purpose of reducing the temperature of the body in certain states of disease—is purely reactionary. The cold bath is only useful, or even safe, when it produces a rapid return of the blood to the surface immediately after the first impression made, whether by immersion or affusion. The surface must quickly redden, and there must be a glow of heat. If these effects are not rapidly apparent, cold bathing is bad; and no such effects are likely to be produced unless the circulation be vigorous and both the heart and bloodvessels are healthy. Great mistakes are made, and serious risks are often incurred, by the unintelligent use of the cold bath by the weakly or unsound. Moreover, it is necessary to bear in mind that there is seldom too much energy to spare after middle age, and it is seldom expedient for persons much over forty to risk cold bathing. We would go so far as to say that no one above that age should use the tub quite cold unless under medical advice. It is possible to be apparently robust and, for all the average purposes of life, healthy, and yet to have such disabilities arising out of organic disease or weakness as to render the recourse to heroic measures, even in the matter of cold bathing, perilous.

THE SANITARY STATE OF WEST COWES.

BOTH those who assail and those who uphold the existing sanitary circumstances prevailing in West Cowes have taken the opportunity to make known their views in the public press. One side asserts that infectious disease prevails there in connexion with states of sewerage and water-supply that should not exist; and the other side, giving an estimate of their own as to the present population, try to prove a low mortality in the place, and also declare that the sewerage has been carried out according to the wishes of the Local Government Board. Most of the statements on both sides are thus far very general, and all we know for certain is that diphtheria has been prevalent in the place. When Mr. Spear's report is issued, the matters in default will probably be specifically referred to, and then they can more advantageously be discussed.

RESIDENCE IN FLATS.

IN connexion with the subject of house rents, the question of residence in flats is being a good deal discussed and its advantages are being advocated. There is one point to which we would advert as worthy of consideration in settling whether a flat is preferable to an entire house. Flats have generally the advantage of being of modern construction, and it may in many cases be inferred that some of the principal evils due to faulty and defective drainage in old houses are avoided in them. But, on the other hand, cases have come to our knowledge in which the drainage of first-class buildings laid out in flats has been found to be seriously defective, and then the tenants find themselves in considerable difficulty, since they are without the control which an ordinary householder has over the general sanitary arrangements of his house. The defect in question is not usually one affecting the drain connexions in the individual flat, but the whole premises suffer from the want of the passage of a constant current of air through the general house drain, such as is secured by the provision of an inlet and outlet pipe on the house side of an efficient trap before

the drain reaches the sewer. Some tenants, after constantly suffering from indisposition from inhalation of drain air, have been compelled to give up their flats. It would be well if owners of flats were to secure a certificate from some expert in sanitary engineering, to the effect that the drainage arrangements affecting the entire establishment were carried out on proper principles.

A CONJOINT EXAMINING BOARD FOR IRELAND.

THE scheme for constituting an Examining Board in Ireland by the College of Physicians and the Royal College of Surgeons in Ireland, under the provisions of Section 19 of the Medical Act, 1858, is almost complete, and but slight modifications of the report presented by the committee appointed by each College may be expected. The Examining Board will consist of twenty-four members, twelve being appointed by each College, who will pay the examiners whom they may appoint. The subjects for examination will be chemistry, physics, materia medica, pharmacy, anatomy, physiology, and histology; medicine, surgery, midwifery, and diseases peculiar to women; therapeutics, forensic medicine, and hygiene; pathology; and the Council of the College of Surgeons propose to add ophthalmic and aural surgery. A committee of management will arrange the examinations and perform other duties; and this committee will consist of three representatives from each College, to be elected annually, and to be disqualified from holding the office of examiner. The committee annually elect a secretary, whose remuneration is to be shared equally by the Colleges. No person engaged in private tuition will be eligible for the post of examiner. There will be four examinations, one at the end of each year of professional study, the student being examined in anatomy in three several years; in physiology on two occasions; chemistry the same; and in surgery in the third and fourth year; while the College of Surgeons recommend at the end of the second year of study an examination in hospital practice—elementary, medical, and surgical; and the same body suggest that in the fourth year the subjects should include ophthalmic and aural surgery. There is very little difference in the number of lectures and the hospital attendance usually required up to this for the licence of either College, and the fees are fixed at the same amount—viz, £42, for which sum the licence of both Colleges can be obtained.

THE CLEARING OF DUSTBINS.

A WELL-KNOWN firm have complained in a contemporary of the nuisance caused to themselves and their customers by the collection of house-dust by the scavengers at two o'clock in the afternoon. Mr. John Braye, a member of the Kensington vestry, writes also to the same journal to say that after much inquiry he finds that "a well-organised early morning collection daily is not more expensive than the old and slovenly system of dustbins. The receptacles are provided by the corporation, they are placed outside the dwelling in the morning, and all the men have to do is to tip the contents into their vans." He cites the arrangements of Glasgow, where it is a common practice to have a daily collection of dust, and says that last year Glasgow sent 186,000 tons of dust to fourteen Scotch counties, and sold it to the farmers for manure, realising a profit of £13,700, after paying upwards of £10,000 for railway carriage. There is indeed not the least doubt that the scavenging of the metropolis could be effected in a far better manner than at present. Some slight difficulty would have to be surmounted in effecting an alteration of a method that has been in existence for years. But this is not the chief obstacle. The real hindrance to any improvement is to be found in the fact which Mr. Braye points out, that "to scavenge the high road from Tattersall's to Charing-cross it takes the divided exertions of no less than six vestries and district boards of works, each with a separate system."

THE DRESS OF FEMALE PAUPERS.

SOME good has probably been done by the City of London Board of Guardians in raising a discussion on the dress of female paupers. It is true the Board came to no actual decision, but they opened the question, and it is one which ought to benefit by investigation. While, in the opinion of some, the check fabrics of light material now in use might be discarded in favour of black stuff dresses, which are less suggestive of public charity, others oppose this change on the ground that black stuff will not wash, and must therefore tend to harbour vermin. The objection, we fear, is a valid one in regard to most kinds of black cloth which are available for this purpose. The composition of such goods—a mixture of wool and vegetable fibre,—apart from the too common instability of modern dyes, renders them unsuitable for washing. As a possible solution of the difficulty, we would suggest that a light material be used as heretofore, the dye being varied if desired, while care is taken that the underclothing (which ought to be woollen) is such as to allow of the same dress being worn at all seasons. A double advantage in comfort and improved appearance might thus be gained.

HÉNOCQUE'S HÆMATOSCOPIC METHOD.

M. HÉNOCQUE exhibited to the Medical Congress at Nancy last month his apparatus for investigating the blood by *hæmatoscopy*. The process consists in first determining the amount of oxyhæmoglobin in the blood by the hæmatoscope, and then estimating the time required for its reduction by observing its passage across the thumb-nail through a direct vision spectroscope. The activity of reduction varies independently of the quantity of oxyhæmoglobin, being generally increased in persons of sanguine habit and in patients with arthritic and rheumatic diseases, and diminished in those with anæmia, chlorosis, epilepsy, temporary bilious disturbances, menstrual troubles, and in certain stages of phthisis.

FACTORY INSPECTORS.

THE Secretary of State for the Home Department, in answer to Mr. Reed, intimated that he did not propose to increase the number of inspectors of factories. This will be a disappointment alike to the advocates of working-class interests and of sanitary reform. To mention only one detail, we have frequently demonstrated in these columns how inadequate is the inspection of the "sweaters' dens" that constitute a permanent scandal in the East-end of London. Mr. Lakeman has spent much energy and time in coping with the evil; but the work is altogether beyond the powers of any one inspector. We have further urged that a detective service should be instituted. No one is, perhaps, better known in the East-end of London than Mr. Lakeman. There is a regular signal by which his approach is notified to all the "sweaters." Thus they have ample time to put their houses in order, to conceal or send away the women and children working beyond the regulation hours, or the extra hands that overcrowd the workshop. No one who is in the least degree acquainted with the subject can doubt that for the proper enforcement of the Factory and Sanitary Acts a much larger number of inspectors is absolutely necessary; and these officials should also be able to employ, at least occasionally, a detective force. Mr. Matthews' answer is, consequently,

very discouraging for those who anticipated that the present Government would forward those legislative and administrative measures which, though unsensational and unpretentious, very largely contribute to the real welfare of the people.

THE PERONEAL TYPE OF PROGRESSIVE MUSCULAR ATROPHY.

THE thesis prepared by Dr. Howard Tooth for the degree of M.D. in the University of Cambridge contains valuable information and an excellent bibliography. The author of the thesis contends that there is a form of progressive muscular atrophy which commences in the lower extremities, most often in the peroneal muscles, but sometimes in the tibialis anticus, extensor longus digitorum, or gastrocnemius; that the hand and forearm muscles are attacked at an early period; that the disease is one of childhood; that heredity is a marked feature; that the disease shows a slight preference for the male sex; that fibrillar or fascicular tremors are frequently, though not always, present; that degenerative electrical reactions are often an early phenomenon; and, lastly, that from a record of necropsies, as well as from the clinical symptoms, it may be inferred that the disease is one affecting the peripheral nerves.

THE SANITARY CONDITION OF WINDSOR.

ON the 14th inst. Mr. Ritchie, President of the Local Government Board, received a deputation from New Windsor, to protest against the charges made by THE LANCET in respect of the insanitary condition of Windsor, and to ask the Local Government Board to appoint an inspector to investigate the subject. Mr. Ritchie, in reply to this request, said that the matter was one of very great importance to Windsor, and that, looking to the exceptional circumstances of the case, he should feel inclined to grant their request. He assumed that the sanitary authority would remedy any defects that might be pointed out. As it was important that the matter should be attended to quickly, Mr. Ritchie intimated that the inquiry would be instituted in the course of a few days.

"SCOTODINIA."

THE term "scotodinia" is probably not often used by medical men nowadays, but it was mentioned recently in the course of consultation, and its precise meaning not being evident to all the members of the consultation, it may be as well to say that the term is used to signify the not unfrequent combination of symptoms of blindness with giddiness. It does not necessarily refer to Menière's disease, for scotodinia is a symptom of a great variety of pathological states, such as gastric disorders, anæmia, and various forms of toxæmia, whether associated with weakened action of the heart or not.

COCAINOMANIA.

ERLENMEYER, in the *Deutsche Medizinal Zeitung* (1886, No. 46), has studied the symptoms in a number of individuals who have used cocaine to excess, by subcutaneous injection or otherwise. The characteristic symptoms denote vasomotor paralysis, the pulse is accelerated, the sweats profuse, and dyspnœa and syncope ensue. Failure of general nutrition is very notable, the eyes become sunken, and the skin of cadaveric hue. At a more advanced stage psychic troubles supervene, sometimes requiring personal restraint. Most of the persons so affected had previously been addicted to the abuse of morphia, and cocaine had been resorted to as a minor evil. It would therefore be unjust to lay too large a share of the troubles noted at the door of cocaine; still, enough evidence is at hand to prove that it may be productive of evil consequences, and should only be used as a powerful medicament with circumspection.

CLEANSING THE BLACKWATER.

WE have from time to time directed attention to the insanitary condition of the low-lying marshes between Aldershot and Wellington College Station, through which the stream known as the Blackwater, a tributary of the Thames, runs. This stream has been for years past clogged with mud and filth, partly derived from the marsh-lands, and much contaminated by sewage deposits, which in the past have been allowed to pollute the stream; it is satisfactory to find the several sanitary authorities having jurisdiction over the districts bounded by this stream, are about to act in concert, with a view to clean out the Blackwater, between Aldershot and Sandhurst. The cost of such a work must be considerable; and it appears reasonable that each district should bear its proportion of the cost. The Blackwater stream forms the boundary of several districts, and is the boundary also of the counties of Berks, Hants, and Surrey, where these counties meet in the valley of the Blackwater. Thus, there are not only several sanitary authorities interested in the subject, but the three counties also. This complicates somewhat the estimate of the proportion each district should bear. We hope this will not interfere with a thorough execution of this much-needed sanitary improvement.

THE SURGERY PROFESSORSHIP IN QUEEN'S COLLEGE, BELFAST.

IN addition to the candidates mentioned in THE LANCET of the 7th ult., it is announced that Dr. Thompson, Surgeon to the County Tyrone Infirmary, is in the field. It is expected that the appointment, which is a Government one, will be made shortly.

FOREIGN UNIVERSITY INTELLIGENCE.

Kharkoff.—Dr. N. Saleski, Extraordinary Professor, has been appointed Professor of Pharmacology.

Leipsig.—Dr. Friederich Albin Hoffman, Professor and Director of the Medical Clinic and Polyclinic in Dorpat, has been appointed Professor of Special Pathology and Therapeutics and Director of the Medical Polyclinic.

Prague (German University).—The Professorship of Midwifery and Gynæcology, vacated by Prof. Breisky, who has gone to Vienna, has been filled by the appointment of Dr. Ludwig Bandl, Extraordinary Professor in Vienna.

Odessa.—Dr. M. Rasumovski has been appointed to lecture on Medical Jurisprudence in the Legal Faculty.

WE regret to learn that Mr. T. M. Stone, so well known to the profession through his services during nearly half a century at the College of Surgeons, when returning from the funeral of the late Dr. Wakley, was seized with a fit or faint, and fell on his face. He was found by a passer-by, bleeding much from his face, and taken to a farmhouse, where he received attention and assistance. He was seen on the following Monday by Mr. Henry Smith, who found he had received a severe wound on his nose and contusion of the face. Mr. Stone, we are glad to say, is now so far well as to be able to drive out.

THE Cama Obstetric Hospital at Bombay, the foundation stone of which was laid in 1883 by H.R.H. the Duke of Connaught, was formally opened on July 30th by her Excellency Lady Reay, the lady president of the Western India Branch of the Association of India for the supply of Female Medical Aid.

MR. WALKER of Newcastle, the public analyst for Carlisle, has announced, as the result of a microscopic examination of the ham forwarded to him by Dr. Henry Barnes, and which was suspected as the cause of the recent poisoning of a Carlisle wedding party, the discovery on several occasions of a bacillus which he is now cultivating in different media. This discovery, it is thought, may lead to a satisfactory elucidation of the mystery which so long surrounded the case. Dr. Page of the Local Government Board has been instructed to assist in the inquiry. Portions of the ham have also been sent to Mr. Watson Cheyne and to Professor Greenfield for examination. We hope to be able to give, probably next week, a detailed history of this interesting case.

SCARLET FEVER, which has existed for several months in the Cumberworth district of the Huddersfield Union, is reported to be greatly on the increase. The district includes the parishes of Cumberworth, Denby Dale, Shelley, and Skelmanthorpe. We are informed on good authority that one practitioner alone has had sixty-one cases brought under his notice.

THE address delivered by Mr. Erichsen in the Surgical Section of the British Medical Association at Brighton has been translated into Spanish by Dr. Ulecia of Madrid, and appears in the current number of the *Revista di Medicina y Cirurgia Practical*, and into Italian by Dr. Longhi of Milan, for the *Gazzetta degli Ospitali*.

THE managers of the Hudson River State Hospital, Poughkeepsie, N.Y., have established, in connexion with the institution under their charge, a training school for the instruction of those who wish to make a specialty of nursing the insane, either in private houses or public institutions.

DR. PEKELHARING, Professor of Medicine in the University of Utrecht, has been instructed by the Government at the Hague to proceed to Acheen to make special inquiry into the nature of the malady known as "beri-beri."

THE proposed special grant to the Belfast Royal Hospital is threatened with strong opposition by Mr. T. W. Russell, who has been promised the support of Mr. Labouchere and several other leading Radicals.

THE nineteenth annual meeting of the Canadian Medical Association was commenced at Quebec on the 18th ult.

THE PRIVY COUNCIL AND THE APPROACHING ELECTION OF DIRECT REPRESENTATIVES.

OUR readers will remember that the Medical Act of 1886 left the making of regulations for guiding the procedure of the Branch Councils in the matter of the election of direct representatives with the Lords of the Privy Council. The *London Gazette* of Sept. 3rd contains the orders and regulations of their lordships. A schedule contains the regulations, and an appendix gives certain forms. Form A is a notice of the election, to be published at least fourteen days before the election in at least two newspapers in the part of the kingdom in which the election is to be held. Form B is the precept of the returning officer, the President of the Medical Council requiring the Branch Council of each division to cause the election of the proper number of representatives. Form C is a form of Nomination paper. Form D is the form of Voting paper, to be prepared and forwarded in due time by the Branch Council of each division to each registered practitioner in that part of the United Kingdom. As the nomination of candidates is the act of the profession, and those nominating are required to keep as nearly as possible to the prescribed form, we append Form C. The other forms are for the guidance of the returning officer or the Branch Councils.

FORM C. (*Form of Nomination Paper.*)

We the undersigned, being registered medical practitioners resident in* , hereby nominate† of‡ a registered medical practitioner, as a proper person to be elected to the General Council of Medical Education and Registration of the United Kingdom by the registered medical practitioners resident in*

(Date) Signed§

* Here insert England, Scotland, or Ireland, as the case may be.
† Here insert name of person nominated, in full.
‡ Here insert address and registered qualification or qualifications of person nominated.
§ To be signed by not fewer than twelve registered medical practitioners, to the signature of each one of whom his address and registered qualification or qualifications must be appended.

The regulations themselves have interest chiefly for the Returning Officer and the Branch Council. But one or two points of interest may be noted. As to the time of the election, the exact date still rests with the returning officer. But their lordships "order and direct" that for the purposes of the next election of direct representatives the returning officer shall, in the course of the period of seven days ending with the 13th November next, *issue his precept to the Branch Council* in each part of the United Kingdom, as required by the eighth section of the Act. Now this said section requires the Branch Council to cause the representatives to be elected within twenty-one days after the receipt of the said precept. This would involve the selection taking place on or before the 4th of December. The last day for sending in the *nomination* papers is to be fixed by the returning officer, and at least fourteen days before the day so fixed the returning officer is to cause a notice of the election to be published specifying the number of persons to be elected, the place where the nomination papers are to be sent in, and the last day on which they are to be sent. This notice is to be published in at least two newspapers. But doubtless the returning officer will publish it in the medical papers for greater certainty of its being seen by nominators of candidates. As to the voting papers, they will be prepared and forwarded by the Branch Council. These papers will contain a list of the candidates, and the voter is to write his initials in the space against the name of the person or persons for whom he intends to vote. Those interested in the election of candidates will do well to supply themselves with a copy of the *London Gazette* of September 3rd.

THE NEW SYDENHAM SOCIETY.

THE twenty-eighth annual meeting of the New Sydenham Society was held in the Pavilion at Brighton, August 13th, Mr. S. W. Sibley in the chair.

The minutes of the last meeting were read and confirmed.

The Secretary read the draft of the report as prepared by the council, and the statement of the Society's income and expenditure; the balance-sheet for 1885 had been duly audited by Dr. Clapton and Mr. Corner, by which it was shown that the receipts amounted to £2092 5*s.* 4*d.* and the expenditure to £2174 2*s.* 2*d.* It was moved by Dr. Moore, of Dublin, and seconded by Mr. Jessop, of Leeds, "That the report and balance-sheet, as presented by the council, be adopted, and, as usual, printed for circulation." For the present, it is intended to restrict the Society's work chiefly to translations of modern books. The work adopted for translation during the year is a series of clinical lectures by Prof. Charcot, now in course of publication.

A ballot of the officers for the ensuing year was next taken, when Sir Spencer Wells was elected president, Dr. Sedgwick Saunders was re-elected treasurer, and Mr. Jonathan Hutchinson, hon. secretary.

The following resolution, moved by Dr. Chadwick, and seconded by Mr. Vincent Jackson, of Wolverhampton, "That the best thanks of the Society be given to the retiring officers for their services during the past year," was carried unanimously. It was moved by Mr. Jones Morris, of Portmadoc, seconded by Mr. Jessop, of Leeds, and carried unanimously, "That the best thanks of the Society be given to the honorary local secretaries, on whose exertions in the past so much of the success of the Society depended.' After a vote of thanks to the Chairman the meeting separated.

THE LATE JAMES G. WAKLEY, M.D.

WE might fill several pages of our present number with grateful tributes to the work and character of the late Dr. Wakley, Editor of THE LANCET. It is very gratifying to those concerned in this Journal to receive such communications, and very painful to them to be unable to publish more than a few of them. Those whose communications do not appear will understand the extreme pressure on our space, and will believe that, even out of deference to him whose loss is so acutely felt, we must use it so as to advance the great ends of Medicine. The following lines are from one whose friendship Dr. Wakley valued much. Their authorship might have been guessed without the appended name, which many English readers will, however, be glad to see, as of one still bound by strong ties to this Journal.

IN MEMORIAM—J. G. W.

Non secus ac flerunt Palinurum Troes ademptum
Per freta nocturnam nave tenente viam,
Defiendus nobis raptus de puppe magister
Pervigil adversas tot superare vices:

Digne, mari rerum, qui mollieris habenas
A patre donatas deficiente manu,
Direxti cursum, medica ducente Minerva,
Quo genus humanum cunque petebat opem.

Ergo perpetuus carum sopor urget amicum
Quem Pudor et lugent cum Probitate Fides?
Cui fuit in terris curae praestare salutem
Illum habet in caelis non peritura Salus.

J. P. STEELE, M.D.

IDEM ANGLICE REDDITUM.

As wept the Trojans wandering o'er the deep
Their missing Palinure's directing power,
We mourn our Palinurus, prompt to keep
Unerring watch through many a fateful hour:

Oh worthy, on life's waters, of the helm
Thy sire bequeath'd thee! In thy yearly course
Thou hall'dst each harbour of the healing realm
Whence Science still could perfect her resource.

Sound is thy slumber; yet, from o'er thy grave,
Unselfish Worth and Faith, in accents soft,
Say: He whose part below was life to save
Shall rise, redeem'd, to better life aloft.

J. P. S.

From medical officers of the Royal Navy letters of condolence have been received, expressive of their sense of their "loss of a sturdy friend and advocate of the rights of their department—one who, during thirty years, never failed to render his aid on every just occasion, by bringing their wrongs and claims to the knowledge of the profession at large, by opening his columns to the communications sent to him by the trusted representatives of the corps."

"THE LANCET" AND THE LATE DR. WAKLEY.

To the Editor of THE LANCET.

SIR,—In one of his essays Bacon says that "they are happy men whose natures sort with their vocations." After reading the articles which have appeared concerning the late Dr. Wakley, I have come to the conclusion that his life was singularly happy. His nature seems to have sorted with his essentially responsible vocation of Editor of THE LANCET in a fashion that is seldom observed amid the feverish changefulness of these latter days. It was indeed fortunate that such was the case, more especially when one remembers and considers the great and, in my opinion, beneficent influence which THE LANCET possessed, and continues to possess, over the words and actions of the medical profession. Under the guidance of Dr. Wakley, it became something more and better than a merely Medical Journal. It has discovered to the profession, and continues to enforce the discovery upon the attention of medical practitioners, the fact that the science of medicine has a higher end before it than is to be found in the every-day work of patching up decrepit humanity. Beyond the usually understood routine of general medical practice there are many questions of moment, with the settlement of which the medical practitioner is concerned. I have always regarded the prevention of disease as the most important part of my duty as a medical practitioner, and I am glad to say that the education of the people in the first principles of sanitary science is becoming the fashion. The necessity for watchfulness in the education of children has frequently been insisted on by the late Editor of THE LANCET. The recognition of insanity in connexion with criminal outbreaks, and the consequently intelligent restriction of the insane criminal; the intimate, and, as I believe, inseparable connexion between physical and mental life; the improvement of the race by means of patient investigation into the wide and far-reaching subject of hereditary transmission of physical virtues and defects; the supply of rational and informing amusements to the multitudes whose thoughts are in their eyes and ears,—with all these, and other questions the medical practitioner is concerned, and it will not be the fault of THE LANCET—if a continuity of its excellent purpose be preserved—if he remain hard and fast in a narrow and thought-obliterating groove.

I have been impelled to write these words by a consideration of the manner in which Dr. Wakley discharged the onerous duties of Editor. For editors in general I have a profound and occasionally panic-stricken respect. They are, in the best and most real sense of the term, absolute monarchs. Dr. Wakley seems to have been a genial and kindly occupant of the editorial throne. For a long period of time, he conducted, with marked and increasing success, a Journal to the words of which, not only a profession singularly jealous of any infringement of its rights, but also the intelligent public, turn an interested ear. He seems to have possessed in full measure a store of that discerning and discriminating wit which, with keen vision, separates the gold from the dross of human life, and without which learning is an unfruitful field; and yet such men as he pass from the knowledge of their kind with little ceremony. A soldier, a man of science, or a leader in literature must die in a rude gothic fashion, on the uncurtained stage of life; but the journalist—the interpreter of the world's incoherent babble—dies after the more decorous fashion of the great dramatist, out of the sight of men. The busy world is astonished for the moment when it learns that the editor of this or that important journal is dead. He had laboured with hearty devotion to the cause in which he was engaged, but his labour had been in secret, or known only to the few who had laboured by his side. The influence, however, that such a man exerts on the course of human life and the character of human action remains as an indefinite and immortal essence, and I am Positivist enough to believe that for the honest and conscientious journalist there is an impersonal immortality of the sweetest and most unselfish kind. I do not know if the breathless world will pause for a moment's reflection upon the worth of such a man as Dr. Wakley, or bewilder itself over the consideration of monument and memorial. To his friends, with whom there is not only the sadness of the recent sorrow, but also the satisfaction of reflecting upon his character and worth, the best monument will be the fragrant memory of his well-spent life.

I am, Sir, yours truly,

Glasgow, Sept. 5th, 1886. ROBERT MACPHERSON.

ARMY MEDICAL DEPARTMENT.

IN the discussion which took place in the House of Commons, in Committee of Supply on the Army Estimates, the condition of the Medical Department, and the grievances, especially of the junior officers, were pretty fully discussed. Colonel Duncan, who spoke with a practical knowledge of the working of the service, appears to regret the substitution of the departmental for the regimental system, as he believed the men were better looked after under the latter, "and the medical officer was emphatically a friend among the other officers." But he admitted that the regimental system could not be worked on active service, and that it was necessary to have the same system in peace as in war. A study of the working of the department in our recent campaigns, compared with that of the later years of the regimental system, most fully confirms this opinion. Colonel Duncan bore valuable testimony to the good service done by the medical officers, and to the courage they had shown in the midst of epidemics and in the field. He brought forward, on their behalf, two distinct grievances: the first being the disproportionate amount of foreign to home service; and the second, the examination of surgeons-major previously to selection for promotion. The first of these has, no doubt, pressed hardly upon medical officers during the past few years, but it has been a result of unforeseen circumstances connected with active war, and from the statement of the Secretary of State for War it appears now to be gradually abating. The other point—that of the examination of surgeons-major—is one of great importance, and on it we cannot agree with the gallant Colonel. The evils of promotion to the administrative ranks by seniority, without reference to the special qualities required, were so clearly shown under the old system, that the Commission presided over by Lord Herbert urged promotion by selection as one of the imperative necessities towards the formation of an efficient service. But if a selection is to be made, it is surely necessary that the Director-General should have the means of ascertaining whether the officers to be selected have a competent knowledge of the details of the service which they are to be called upon to administer, and we cannot see how this can be ascertained satisfactorily in any other way than by examination. It was stated as a grievance by several members that medical officers were not afforded an opportunity of "attending London or other hospitals in order to qualify themselves to pass their examinations." But they appear to have overlooked the fact that the subjects of examination are all connected with the administrative duties of the army, and that neither in London nor elsewhere are any lectures delivered which could be of the slightest use for this purpose. It might be a question for the War Office to consider whether a special course of instruction could not be instituted at Netley—a sort of medical staff college; but we fear there would be great practical difficulties. If a surgeon-major cannot in the course of his service acquire a sufficient amount of knowledge of departmental organisation and duties to enable him to pass the requisite examination, we should be disposed to consider it evidence of his unfitness for selection to the higher grades. Colonel Duncan offered a practical suggestion which seems worthy of consideration—"that it would be better if at the large military stations a field hospital were kept constantly standing and fully organised, so that all those in charge of it may be fully trained." Such a course would merely be in accord with the acknowledged necessity for having the same system in peace as in war. We observe with much regret that Dr. Tanner did not follow the example of Colonel Duncan and sum up temperately what are considered the real grievances of the department, but made statements which might have been applicable to the service in former times, but are certainly not so now. He alleged that "the army only got medical officers who were more or less the ruck and scum of the schools, and consequently the soldiers did not get that care and attention to which they were entitled in time of peace; and in time of war the state of things was still more deplorable." When this statement was indignantly repudiated by the Secretary of State for War, it was modified by Dr. Tanner as being applicable to the past, but not actually to the present time. We regret that a member of our profession should have made so loose and inaccurate a statement reflecting discredit upon the medical officers of the army. Complaint was also made by him that the "army medical officers were being constantly sent about from one station to another without having adequate notice given them, which he contended was a great hardship to them, and detrimental to the efficiency of the service." And again he repeated his complaint "that junior medical officers were constantly being sent about the country and not allowed to remain in one district." We hardly suppose the honourable member means that they are sent about in this way for the amusement of the Director-General, or that they should be spared the hardship and the seniors be sent on such duty in their stead. We observe, with satisfaction, that Mr. W. H. Smith spoke in high terms of the "many excellent medical officers to whom the British soldier owed a deep debt of gratitude," and that he has promised to give consideration to the various points raised during the debate, and to improve the condition of the medical officer so far as possible consistently with the interests of the tax-payer.

In reliance upon the expressed intentions of the right hon. gentleman, we would bring to his notice two grievances which appear to us to call imperatively for redress, and which would involve little or no expense. The first regards the gazetting of "surgeons on probation" to commissions. It appears that the commissions of those for the Indian Medical Service are dated from the period of joining at Netley, while those for the Army Medical Department bear the date on which the course of instruction there closes. The practical result of this difference is, that the Indian medical officers become the seniors of the others by four months, and this seniority must continue throughout their career, at least till they reach the administrative ranks. This is so obviously unjust that we feel it should only be necessary to bring it to the notice of the Secretary of State for War to have it remedied. Unless this is done, the difference of treatment cannot fail to act most injuriously upon the supply of candidates for the Army Medical Department. Formerly the rule of dating from the period of joining at Netley applied to both services, but the change was effected by the Warrant of 1877, for reasons which have never been explained. The other grievance is that while honours are conferred upon medical officers for service in the field, no notice is taken of their professional services, often rendered under circumstances of great difficulty and more personal danger, in the treatment of severe epidemics. The duties of the medical officers in saving life by these measures which tend to prevent disease, and their care and exertions in the treatment of the sick, more especially during the ravages of epidemics, are at least as commendable and as valuable to the army as their surgical work in the field; but under the present routine they are systematically ignored. We recommend this subject to the serious consideration of the Secretary of State, in the hope that he may find means to remedy the grievance without affecting the interests of the taxpayer.

THE DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

A MEETING of the General Committee, which has been formed to consider the selection of candidates for the representation on the General Medical Council of the profession according to the provisions of the Medical Amendment Act, was held at the Queen's Hotel, Birmingham, on Tuesday, the 14th inst.

Among those present were: Dr. Saundby (Birmingham), Dr. Waters (Chester), Dr. Roden (Droitwich), Dr. W. Armstrong (Manchester), Dr. Berry (Wigan), Dr. Danford Thomas (London), Dr. Crow (Worcester), Dr. Paul Chapman (Hereford), Dr. Strange (Worcester), Dr. Pike (Malvern), Dr. Lyle (Bromsgrove), Dr. Eyton Jones (Wrexham), Dr. Suckling (Birmingham), Dr. Farrar (Morecombe), Mr. R. H. Nicholson (Hull), Mr. Lawson Tait, Mr. D. Vinrace, Mr. Bennett-May, Mr. Jordan Lloyd (Birmingham), Mr. Wheelhouse (Leeds), Mr. Granger (Chester), Mr. Taylor (Chester), Mr. Lowe (Burton), Mr. Barron (Southport), Mr. Vincent Jackson (Wolverhampton), Mr. S. Walker (Birkenhead),

Dr. Bates (Nottingham), and Dr. Carter and Dr. Ker (honorary secretaries).

Dr. Strange having been appointed chairman, Dr. CARTER read letters of apology for non-attendance, some of which contained suggestions for the meeting, some nominated candidates, and others expressed the desire that certain gentlemen should be nominated.

The CHAIRMAN said that the meeting was of the committee of gentlemen who had signified their desire to act on a general committee for the purpose of hearing names of candidates for the three seats on the Medical Council and to deliberate on these names. To put the meeting in order the circular convening the assembly was then read, which stated that the object of the meeting was to "ascertain the wish of the medical profession as to the most suitable representatives to return to the Medical Council."

Dr. CARTER explained that invitations to the meeting had only been sent out to those gentlemen who had already expressed a desire to be members of the General Committee. That General Committee had been formed by invitations to the extent of 1167, which he and Dr. Ker as hon. secretaries had sent out.

The CHAIRMAN then formally opened the meeting. After a very long struggle, he said, on the part of the members of the Reform Committee of the British Medical Association, and particularly of the Committee's chairman, Dr. Waters, they had obtained the Amended Medical Act. That Act conferred on the profession privileges hitherto denied them. In the original draft of the Bill two representatives on the Medical Council were accorded to England and Wales, one to Scotland, and one to Ireland. By the efforts of Sir Walter Foster the English representation was increased to three. The selection of the first three representatives was decidedly an epoch in the history of the profession. Hitherto the professional representation had been confined to the universities and Royal Colleges, and the representatives on the Medical Council thus sent might be men of eminence and trusted representatives of the great bodies that sent them, still they were not representative of the general practitioners of the country, and they were not representative of the universality of the profession. Now, however, this universality of representation would be secured by the amended Act; and he hoped the general practitioners of the country would return to the Medical Council men who were in harmony with the general feeling of the practitioners throughout the country. They were assembled now to ascertain what would be the best means by which they should select these three representatives. In a vast body like the medical men of England and Wales, numbering over 20,000, it would be an extremely difficult matter to manage an election at all, and all the more difficult in that they had no organisation or settled plan by which they could decide as to the merits of the respective candidates. He thought they should endeavour to get representatives who from their position in the profession and for the work they had done would secure the confidence of all—men, too, who had leisure to do the duties thoroughly. He need not say anything about the origin of the present meeting. It was of no consequence what had been done in the past—what took place at Brighton,—because they had now done what was originally intended, they had applied to the whole profession. Something like 1000 or 1100 circulars had been sent out inviting gentlemen to take part in the General Committee, and over 200 representatives had answered the circular from upwards of 100 towns and villages. They could not therefore be accused of cliquism, and the present meeting was thoroughly representative of the profession. They might therefore proceed at once to consider the claims of certain persons who would be presented to them, and to put the proceedings in order he would call upon Dr. Eyton Jones to propose a resolution.

Dr. EYTON JONES then moved "That this meeting, fully impressed with the extreme importance of the present crisis in the history of the English medical profession occasioned by the right acquired in the recent Medical Act of electing three representatives of their body on the General Medical Council, deems it expedient to proceed at once to deliberate on the merits of the various candidates for such representation, and to solicit by requisition three fit and proper persons to undertake the office." As the British Medical Association was originally a provincial organisation, and as the General Medical Council had in the past been represented by men taken from the centres of learning—London, Edinburgh, and Dublin,—now the medical practitioners of the provinces should be represented by the three additional members they had to select as a balance, though a small one, against those that had hitherto been selected by the Universities and the Corporations, and nominated by the Government. They should show in so far as they could in their selection of these three candidates their desire to have a voice in the legislative body of the profession, and they should therefore select men who knew the conditions and the necessities of the general practitioner, and who would speak up for them manfully and openly on the General Medical Council. (Applause.) The Council had hitherto acted principally in the direction of the education of the future practitioners, and in consequence, the rights of the present practitioners had suffered. Many questions would crop up when they had popular representation on the Medical Council, and they should have representatives on it who would be able to take their part because they themselves had experienced their grievances.

Mr. LAWSON TAIT, in seconding the resolution, said he could not help feeling that it was but a scant reward for the trouble Dr. Ker and Dr. Carter had taken in sending out so many circulars to find that so few should have expressed their enthusiasm in the question by attending the meeting, and thus leaving in the hands of these few the responsible work of selecting the first three representatives to the General Medical Council. He for one had not great enthusiasm in that direction, because he thought their efforts might have been better directed towards the reconstruction of that General Council. It seemed to him a great waste of money and of time for people to be appointed on that Council, whose only duty appeared to be to meet together and make long speeches, people who had no connexion and no sympathy with the medical profession, and who know nothing about its wants or its abuses. (Hear, hear.) He accepted the political principle of having direct representation to a small extent on the General Council, and he trusted his fellow practitioners would exercise due discretion in the selection of the candidates they sent to represent them. He hoped they would not select representatives who were in the clouds of the medical profession, men who had little association with the feelings or the aspirations of the bulk of the practitioners in the country; also that they would not choose their representatives merely by their seniority. (Applause.) What they wanted was three men who would expose and try to reform a great many of the abuses in the General Medical Council. (Hear, hear.)

At the request of Dr. Danford Thomas, Dr. CARTER stated that the number of responses received to the circular to take part in the General Committee for the selection of the candidates was 343 up to that day, and that number represented 161 towns from all parts of England and Wales.

The CHAIRMAN, answering a second question of Dr. Danford Thomas as to whether the meeting intended to select right off three representatives, said that at the present the meeting was very small, but he hoped it would enlarge to enable them to take some decisive action. The resolution now proposed did not necessarily bind the meeting to select three representatives then.

Dr. DANFORD THOMAS.—We are not yet twenty-five.

Dr. KER.—I have counted thirty-two. (Laughter.)

The CHAIRMAN did not think they should hesitate about proceeding, because the business of the meeting was to discuss the merits of candidates to be nominated. He did not expect more than fifty to attend the meeting, and those that were present were thoroughly representative.

Mr. NICHOLSON said that the meeting might be adjourned considering the sparse attendance, and that its duties should be relegated to a small committee. Some present had travelled long distances, and did not like the idea of adjournment.

The resolution was then put to the meeting, and carried.

Dr. CARTER then proceeded to read the correspondence he had received containing suggestions and proposing candidates. There was a sort of honourable understanding, he said, that every name that had been before the profession, whether sent to Dr. Ker or himself as the secretaries of that committee, or mentioned in any of the medical journals, should be put before the meeting. One suggestion made was that all the representatives should be general practitioners only, another that the present meeting should be preliminary to another, which would make the final selection. (Hear, hear.) Dr. Taaffe of Brighton wrote saying he was a candidate for the representation, and asking to be

brought forward as such. Dr. Stokes of Highbury, London, wrote, as chairman of a committee who were forwarding the candidature of Dr. Glover of London, asking how that gentleman's name could be brought before the present meeting, and a correspondence had taken place between him (Dr. Carter) and Mr. Stokes on the matter. He says "that Dr. Glover's name would be sure to be brought forward. Dr. Sympson of Lincoln and others had also written recommending Dr. Glover's candidature. Dr. Partridge and Dr. Shuttleworth of Lancaster and others had suggested Sir B. Walter Foster as a candidate. (Hear, hear.) A memorial had been sent up from Cambridge in favour of Dr. Bridger, and others recommended by letter were Mr. D. B. Balding of Royston, Dr. Dolan of Halifax (who was strongly recommended by Dr. Rabagliati of Bradford), Dr. B. W. Richardson, Mr. Wheelhouse of Leeds, Mr. Hart of London, Sir Andrew Clark, Mr. Holman of Reigate, Dr. Waters of Chester, Dr. Harrow, and Dr. Morris of Spalding.

In answer to Dr. Danford Thomas, the CHAIRMAN said they had no intimation from any of the candidates that they would stand if elected.

Mr. NICHOLSON suggested that the best way to proceed would be for the secretary of the committee to make out a list of all the nominations to be sent to every member of the General Committee, and each member to send back his list with the three names marked that he approved of. He thought this all the more desirable, seeing the small dimensions of the present meeting. For his own part, he believed Mr. Wheelhouse of Leeds would represent best the practitioners of the north of England. (Applause.) He was a thoroughly representative man, and, he believed, would be elected. He would put his suggestion into the form of a resolution.

On this intimation, Dr. WATERS said he would second it.

The CHAIRMAN asked Mr. Nicholson to abstain from bringing forward his resolution till after the nominations. So far, the thing had only taken the shape of suggestions. Besides, others were eligible for candidature besides those suggested by letters received. Anyone at that meeting could propose whomsoever he chose. By the resolution already passed, too, they had resolved to deliberate upon the names brought forward.

Mr. NICHOLSON consented to postpone his resolution till the nominations were completed.

Dr. BARRON then said he thought it would be highly desirable to divide the whole of England into three divisions, the north, the midlands, and the south. (Hear, hear.) A candidate that might suit the practitioners of the south of England would not necessarily suit the north, and *vice versâ*. He therefore advocated this division of the country with the object of each division securing a representative that would be thoroughly representative of its practitioners by his personal knowledge of their different necessities and grievances.

Mr. VINCENT JACKSON highly approved of Dr. Barron's suggestion. By such an arrangement the work of selection would be made very much easier; they would be likely to get representatives who would please everyone, and the selection would be greatly simplified.

Dr. WATERS said there was no advantage to be obtained in dividing the country into three divisions, for they could not divide the electorate with it. Each practitioner in each division would be able to vote for three candidates; they could not restrict him to vote for one for his division only.

Mr. LAWSON TAIT said the proposition appeared to him absurd and illogical. He could not imagine anything more likely to defeat the object they had in view than such a division of the country. He suggested that, without regard to location, they should select three of the most active, young, and discontented men in the profession, the more active and discontented the better. (Laughter and applause.) They wanted the General Medical Council reformed, and these were the sort of men to do it.

The CHAIRMAN said it was almost the first time in his life he had differed with Mr. Lawson Tait, but he differed with him on that point. It might be a little childish and somewhat illogical; but he believed it would enable them to secure the best men.

Mr. BARRON objected to the suggestion being characterised as either childish or illogical. He would not have proposed it if he had thought it either of these; but, on the contrary, he considered it very good sound sense.

The CHAIRMAN.—I will withdraw the word "childish" if Mr. Tait will withdraw the word "illogical."

Mr. TAIT.—I will withdraw it if you wish it, but the withdrawal does not alter my opinion.

After a deal of desultory discussion as to the procedure in the selection of the representatives, it was at length decided to proceed with the nomination of candidates.

Dr. EYTON JONES proposed Mr. Wheelhouse of Leeds, and after Dr. Berry had interposed with a question as to where the expenses for the election were to come from, Mr. Nicholson seconded the nomination, saying he felt sure Mr. Wheelhouse would be elected by the votes of the north of England practitioners.

Dr. DONOGHUE doubted whether Mr. Nicholson was quite correct in his estimate of the vote that would be given to Mr. Wheelhouse in the north of England.

Dr. Glover, of London, was next proposed by Mr. KER, and seconded by Dr. WHEELHOUSE, who said that if any man knew the requirements of the profession Dr. Glover did.

Mr. LAWSON TAIT thought that considering his connexion with THE LANCET, and the part that Journal had taken in bringing about the amendment of the Medical Act, Dr. Glover should certainly be one of the three chosen representatives. He was sure to be on the discontented side of the question.

Sir Walter Foster was the next nomination, the nominator being Mr. NICHOLSON, and the seconder Dr. BARRON. Dr. Barron said if it was only to show their gratitude for the increased representation they had got by Sir Walter Foster's exertions, they should elect him as a representative.

Mr. ARMSTRONG next nominated Dr. Dolan, of Halifax; and the others put forward were Mr. Hart, of London, by Dr. WATERS; Dr. B. W. Richardson, by Dr. DANFORD THOMAS; Dr. Bridgewater, of Harrow, by Mr. NICHOLSON; and Dr. Holman, of Reigate, by Dr. WATERS.

Cries of "Vote" were then raised, and as several gentlemen had left the meeting while the nominations were taking place, Mr. NICHOLSON said it would be absurd, under the circumstances, to take a vote. The other names suggested by letter for candidature, but not formally proposed, were then read over, and Dr. Balding of Reigate and Dr. Morris of Spalding found nominators, but no one put forward the name of Dr. Taaffe of Brighton.

Mr. NICHOLSON then proposed that the names thus nominated at the meeting be sent to all the members of the General Committee, and the vote on them be taken by postcard, the three that received the highest number of votes to be the adopted candidates of the committee for representation on the General Medical Council.

After some discussion as to this resolution clashing with the one already passed, it was decided to entertain it, and, on the vote being taken, it was carried by 11 votes to 3, many of those present at the earlier part of the meeting having left.

The meeting was then concluded with a vote of thanks to the chairman for presiding.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5784 births and 3939 deaths were registered during the week ending Sept. 11th. The annual death-rate in these towns, which had steadily increased in the preceding four weeks from 18·9 to 20·8, further rose last week to 22·6. During the first ten weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1876–85. The lowest rates in these towns last week were 13·9 in Bristol, 16·5 in London, 19·1 in Plymouth, and 20·0 in Huddersfield. The rates in the other towns ranged upwards to 31·9 in Nottingham and in Bolton, 34·8 in Leicester, 35·1 in Norwich, and 38·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 778 and 931 in the preceding two weeks, further rose last week to 1199; they included 995 from diarrhœa (exclusive of 21 attributed to simple cholera), 50 from whooping-cough, 49 from "fever" (principally enteric), 46 from scarlet fever, 38 from measles, 20 from diphtheria, and 1 from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Bristol, London, and Plymouth; and the highest in Nottingham, Hull, and Norwich. Diarrhœa caused the highest death-rates in Leicester, Preston, Hull, and Norwich; whooping-cough in Preston; scarlet

fever in Salford and Huddersfield; "fever" in Norwich and Portsmouth; and measles in Nottingham. The 20 deaths from diphtheria included 9 in London, 2 in Portsmouth, 2 in Liverpool, and 2 in Salford. Small-pox caused 1 death in London and its outer ring, but not one in any of the twenty-seven large provincial towns. No small-pox patients were under treatment in the metropolitan asylum hospitals situated in and around London. The deaths referred to diseases of the respiratory organs in London, which had been 160 and 128 in the preceding two weeks, further fell last week to 110, which were 58 below the corrected average, and considerably fewer than those returned in any previous week of this year. The causes of 99, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Sunderland, Portsmouth, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Sheffield, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7 and 19·4 per 1000 in the preceding two weeks, further rose to 20·6 in the week ending September 11th; this rate was 2·0 per 1000 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·1 and 15·7 in Perth and Dundee, to 24·3 in Paisley and 28·0 in Aberdeen. The 508 deaths in the eight towns last week showed an increase of 21 upon the number in the previous week, and included 57 which were referred to diarrhœa, 20 to whooping-cough, 7 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 4 to diphtheria, 1 to measles, and not one to small-pox; in all, 93 deaths resulted from these principal zymotic diseases, against numbers increasing from 63 to 86 in the preceding four weeks. These 93 deaths were equal to an annual rate of 3·8 per 1000, which was 3·1 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had been 23, 36, and 53 in the previous three weeks, further rose last week to 57, of which 20 occurred in Glasgow, 9 in Dundee, and 7 in Aberdeen. The annual death-rate from diarrhœa in the eight Scotch towns last week did not, however, average more than 2·3 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 5·7. The fatal cases of whooping-cough, which had been 22, 19, and 10 in the preceding three weeks, rose again last week to 20, of which 15 occurred in Glasgow. The 7 deaths from scarlet fever, all of which were returned in Glasgow, showed a further decline from the numbers in the previous two weeks. The deaths referred to "fever" had also declined, and the fatal cases of diphtheria were also below the average. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 67 and 56 in the preceding two weeks, rose again last week to 72, and exceeded by 15 the number in the corresponding week of last year. The causes of 72, or more than 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 18·2 and 26·2 per 1000 in the preceding two weeks, declined again to 25·9 in the week ending Sept. 11th. During the first ten weeks of the current quarter the death-rate [illegible] city averaged 21·2; the mean rate during the same [illegible]ted was 19·3 in London and 18·2 in Edinburgh. The [illegible]eaths in Dublin last week showed a decline of 2 [illegible]Ettonumber in the previous week, and included 26 [illegible]ed wereferred to diarrhœa, 7 to scarlet fever, 4 to [illegible]istory es, enteric, or simple), 1 to whooping-cough, [illegible]t acether to small-pox, measles, or diphtheria. [illegible]sent resulted from the principal zymotic diseases, [illegible]ns 22 in the preceding two weeks; they were [illegible]nnual rate of 5·6 per 1000, the rates from the last week being 3·4 in London and 2·0 in [illegible]he fatal cases of diarrhœa, which had been [illegible]eceding two weeks, further rose last week [illegible] the number in any previous week of [illegible]aths from scarlet fever also showed an increase upon recent weekly numbers; whereas the 4 deaths from "fever" showed a decline of 4 from the number in the previous week. Three inquest cases and 4 deaths from violence were registered; and 29, or one-sixth of the deaths, were recorded in public institutions. The deaths of infants showed a further increase upon the numbers in recent weeks, while those of elderly persons had slightly declined. The causes of 39, or more than 22 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

CHOLERA AND THE WATER-SUPPLY OF MADRAS.

To the Editor of THE LANCET.

SIR,—At a time when cholera is such an interesting question in England, the following table, showing the decrease in mortality in an Oriental town from this pest since it has been favoured with a comparatively pure water-supply, may not be without interest. The Red Hills tank is a large sheet of water some ten or twelve miles from Madras. It is a rain-fed tank, and not cleaner than such tanks, undefiled, would be; but it has this advantage: it has no villages near it, it is away from any thoroughfare, and consequently undefiled by foot-passengers and pilgrims; it is, moreover, scrupulously conserved. The water is led into Madras, first, by a channel more or less well protected, and then the water is distributed over the town by pipes. Even the deaths which have occurred in Madras are found to have mostly taken place in outlying parts of the town, where the Red Hills water has not yet been laid on, except in one district, Triplicane. Here live a large number of Mussulmans, and their women, being Gosha—i.e., not allowed to be seen by any but their own family, are obliged to draw their water from small wells in their back-yards, always perilously near the cesspits.

Return showing the deaths from Cholera in the Town of Madras from 1855 to 1884.

Year.	Deaths from cholera.	Remarks.
1855	1956	—
1856	805	—
1857	1378	—
1858	1965	—
1859	1082	—
1860	2580	—
1861	2776	—
1862	3635	—
1863	1684	—
1864	574	—
1865	944	—
1866	2984	—
1867	614	—
1868	13	—
1869	568	—
1870	861	—
1871	493	—
1872	5	Red Hills water-supply opened.
1873	6	—
1874	0	—
1875	879	Famine years.
1876	2035	Famine years.
1877	6246	Famine years.
1878	64	—
1879	34	—
1880	2	—
1881	123	A very severe epidemic throughout the Presidency.
1882	361	A very severe epidemic throughout the Presidency.
1883	168	A very severe epidemic throughout the Presidency.
1884	269	A very severe epidemic throughout the Presidency.

During 1881–84, the Madras Presidency was visited with one of the severest epidemics of cholera on record, and yet it will be seen that the mortality in Madras city itself was comparatively slight. Two or three times it reappeared in the town coincidentally with the return of pilgrims from

some religious gathering, but it died out. During the four years, the European community were singularly free. I can remember only two cases, and, oddly enough, one of these was a teetotaler. The famine years are scarcely worth taking into consideration; during 1876 and 1877, the people from surrounding districts simply flocked in to die. Every case almost was called cholera; it was simple, and saved trouble.

Such a table as the above points, I think, very forcibly to the advantages which would accrue from having every town in India furnished with a pure water-supply; and this, with the authority of Government, might easily be carried out.

I am, Sir, yours truly,

Madras. M. C. FURNELL, M.D., Surg.-Gen.

"SPAYING," OR REMOVAL OF THE UTERINE APPENDAGES?

To the Editor of THE LANCET.

SIR,—The fact that you have devoted a leader to this question of nomenclature shows that you agree with me at least in its importance. I object to the term "spaying" because it is altogether a false term, and I think you will allow me to argue this view as briefly as I can.

First of all it is false, because in spaying animals the Fallopian tubes are not removed habitually; that is, some of those who operate on the animals do remove the tubes and others do not, a fact of which I have satisfied myself by actually seeing it done. The removal of the ovaries only of an infantile animal seems quite enough to prevent the changes of puberty. Removal of the ovaries alone in cases of myoma and chronic inflammatory disease of the appendages of adult women would not be enough to procure the desired results, and very often the ovaries may be left with distinct advantage if the tubes are thoroughly removed. I have published quite enough on this subject to satisfy any reasonable inquiry, and I have much more material nearly ready for publication, the conclusions from which are all in the same direction. The very pathological changes induced by the diseases for which the operations are performed, as proved by numerous specimens exhibited at many societies, establish anatomical differences enough to make us regard "spaying" as an operation quite different from "removal of the uterine appendages."

You say that an operation should be named not by reason of the motive with which, or the purpose for which, it is done, but according to its nature from an anatomical point of view. Will you permit me to say that I think you have hardly sufficiently considered the effect of such a conclusion, as you may come to an altogether different opinon if you apply your principle in other directions. Thus the hari-kari of the Japanese Daimio and the abdominal section of an approved operation are, *anatomically*, quite the same. Are we therefore to speak in a serious medical journal of them both as "belly-ripping?" Would you seriously undertake to publish a paper of mine with the title—"A Series of Five Hundred Consecutive Belly-rippings"?

The operation performed by the obstetric physician for the induction of premature labour and the illegal proceedings of the abortion-monger are, *anatomically*, exactly the same, yet is not the nomenclature *entirely* influenced by the "motive with which, or the purpose for which," these operations are undertaken? Would not a jury and a judge take motive and purpose very prominently into account as to the definition and means of each of these operations?

Again, you say that "spaying" does not consist in the removal of an ovary still functionally active, and this, being quite true, is the basis of my objection to the application of the word in human surgery. "Spaying" is the removal of both ovaries long before they are functionally active. "Removal of the uterine appendages" is an operation for the removal of either one or both ovaries or tubes long after they have become functionally active; and from these facts alone there is an immense anatomical difference between the two operations, which makes a common nomenclature like impossible and improper.

You say that "spaying" is the removal of both ovaries; how is it possible, then, to class under such a word a case where one or both tubes are removed as chronic abscesses, the ovaries being left? How am I to class under it a case where I remove one tube for a ruptured tubal pregnancy and leave both ovaries? Or if we happen to remove both ovaries for large cystic tumours, are we still to call it a case of "spaying"? The advantage of the term I advocate is, clearly, that it is comprehensive, and admits of classification in a much more orderly fashion than can be done in any other way. And let me here say that I entirely agree with you that to speak of Battey's, or Tait's, or Hegar's operations is very foolish, and is productive of endless confusion. I have never ceased to protest against it so far as my own name is concerned, and for a very simple reason, which I have put on record very many times. Battey originally proposed the operation of removing the ovaries in cases where there was no actual disease of them for the purpose of indirectly influencing neurotic conditions. My first operation was removal of a small ovary, the subject of an abscess; my second, the removal of the appendages for uterine myoma; and to these and similar physical conditions I have, with a very small number of exceptions, confined my work. Hegar's proceeding was for myoma entirely. To speak, therefore, of all operations for removal of the appendages by any one of the three names is to commit an absurdity.

Of course every woman submitted to an operation should be made aware of what is really going to be done to her, not only in this instance but in every other; and not only every woman, but every man: that is, they should be made to understand it as fully as their intelligence admits of. This view really constitutes the greatest argument against the use of the word "spaying," for it is "understanded of the people" as having intentions and results so absolutely foreign to the intentions and results of "removal of the uterine appendages," that I am not at all surprised at the row in Liverpool, and the unusual results brought about by it, now that we have an admission from Dr. Grimsdale of what he has been doing and saying. When I heard him say in the witness box that "ovariotomy did not necessarily include removal of the ovary," I suspected he was living in an atmosphere of confusion: now I know he has created it, and, by his own confession, he is responsible for results deeply to be regretted, not only for abdominal surgery but for the credit of the whole profession. In his evidence, Dr. Grimsdale clearly threw blame on Dr. Imlach for performing operations without consultations. If Dr. Imlach did this, then Dr. Grimsdale was clearly to blame for it. As consulting officer to the hospital, he could have insisted on consultations being held, and if they had been refused his remedy lay in an appeal to the Committee of the Hospital by a complaint that an important law was broken and defied. Instead of this he appealed to outside authority in such fashion as led to most discreditable proceedings.

I am, Sir, yours truly,

Birmingham, Sept. 4th, 1880. LAWSON TAIT.

To the Editor of THE LANCET.

SIR,—Had not Dr. Imlach made indirect reference to the other members of the staff of the Liverpool Hospital for Women in your issue of Sept. 4th by saying that he was the only one of them who had performed the operation of castration for hæmatocele and hæmatosalpinx, I should not have intruded into this discussion. I am proud to say that Dr. Imlach's statement is perfectly correct as far as I am concerned, and I believe also as regards Dr. Lupton, who is suffering from a lingering illness and unable to answer for himself. I have never performed spaying operations for either hæmatocele or hæmatosalpinx. It is also a fact that I have never yet lost a patient from either of these diseases, nor had one that did not completely recover.

Being, however, surgeon to the same hospital, I must necessarily have had to treat the very same classes of cases as Dr. Imlach, and if in the space of three years he has had a considerable number of these cases, it follows almost as a matter of course that I have also treated a considerable number, unless it has happened that they all went to him, and consequently none to me. I do not believe this has been the case. The case stands thus, then: Dr. Imlach has treated a certain number of these cases by mutilation, with three deaths, and I, in common with large numbers of surgeons, have treated a number nearly as large, with not only no deaths and no mutilation, but with complete recovery and without abdominal section.

I will concede that the laparotomist has one advantage over the surgeon who treats his cases in less sensational ways: his diagnosis is more accurate; and this is so from the fact that the laparotomist makes his diagnosis by open-

ing the abdomen. We have no evidence whatever that these cases were diagnosed before the abdomen was opened. Let us suppose for a moment that the abdomen had not been opened in these cases of Dr. Imlach's—the diagnosis would then have been incomplete; but the cases would have been none the less cases of hæmatocele and hæmatosalpinx, and by another surgeon would have been treated with complete success on ordinary lines. Great numbers of these cases are treated under their own or different names every year, and the patients are perhaps all the better for the doubt in the diagnosis. The surgeons who perform abdominal section in these cases do not do it *for* these diseases—i.e., knowingly,—but because the symptoms point to *something* being wrong in the pelvis. They do not know what the "something" is, but, opening the abdomen before the morbid condition has had time to right itself, they are equally surprised at the discovery they have made and proud of the achievement. The accuracy of diagnosis after opening the abdomen is, I grant, admirable; but, to my mind, this does not compensate for the inevitable loss of life that attends the making of it. I am, Sir, yours obediently,

J. E. BURTON,
Surgeon to the Hospital for Women, Liverpool.

Liverpool, Sept. 7th, 1886.

To the Editor of THE LANCET.

SIR,—In reply to Mr. Lawson Tait's letter which appears in THE LANCET of the 21st ult., wherein he states that the operation of spaying an animal and the removal of the uterine appendages from the human being have no conceivable resemblance, consequently to talk of spaying women "is to display great ignorance or to indulge in wilful misrepresentation for purposes of giving offence," I beg to say, with all due respect to that gentleman, that I differ from him. I have spayed some thousands of animals—both those that have not and those that have arrived at puberty. In the latter subjects the ovaries only are removed; in the former the uterine appendages are removed altogether, and it is an undoubted fact that after such an operation has been performed it rarely does destroy the sexual powers and desire, providing the operation has been performed properly; but if there is a small portion of the ovary, or "pride," which it is commonly called, unremoved "or not clean cut," then there will be an over-excess of desire left. If the ovaries only or the uterine appendages altogether are removed, the subject is really spayed or castrated; and the same term will apply to the human being as well as the brute.

I am, Sir, yours faithfully,
Cranham-road, Sept. 1886. C. E. ONSLOW, Vet. Surg.

"THE DIRECT REPRESENTATION OF THE PROFESSION."

To the Editor of THE LANCET.

SIR, May I be allowed to reply to your correspondent who asks why Birmingham was selected as the place of meeting of the committee formed at Brighton? It was simply because that town was thought to be the most centrally situated and generally accessible of all the large towns in the kingdom. Many places were mentioned, but none other seemed on the whole so convenient, and hence it was ultimately selected. The committee, which is now a very large one and comprises numerous representatives from no less than 124 towns and districts of England and Wales, has but a single aim, and that is to endeavour by consultation to ascertain what three medical men would be likely most efficiently to defend the interests of the great body of general practitioners in the General Medical Council. It shrinks from any attempt, and hopes that it may not be thought to have the slightest desire, to dictate. Its aim is consultative. It invites every registered medical practitioner to give it the benefit of his opinions and advice in this most important matter. There must be some kind of organisation unless votes are to be given aimlessly. Organisations already exist. This one, being absolutely unpledged, aims at ascertaining the wishes of the profession; when it has ascertained them, it hopes by concerted action to be able to give effect to them.

I am, Sir, yours faithfully,
Liverpool, Sept. 6th, 1886. WILLIAM CARTER.

*** We regret that, owing to the number being specially devoted to educational matter, we were unable to insert this letter last week.—ED. L.

THE HOSPITAL FOR WOMEN, LIVERPOOL.

To the Editor of THE LANCET.

SIR,—The first paragraph of Dr. Imlach's letter in your issue of September 4th is both incorrect and misleading. I did not at the Casey *v.* Imlach trial "state on oath that the mortality in cases where this operation—i.e., abdominal section had been performed at the Hospital for Women was 33 per cent.," as Dr. Imlach says I did. What I did say was, that the operation to which Mrs. Casey was subjected—i.e., the removal of the uterine appendages for hæmatocele and hæmatosalpinx, an operation to which abdominal section is but the necessary preliminary or exploratory incision—had been fatal in the Hospital for Women during the year 1885, as shown by the Annual Medical Report, in the ratio of 33 per cent. In support of this assertion, I do not intend to follow Dr. Imlach in his vain endeavours to mystify or evade the single point at issue, but will content myself with giving an exact copy from the Report itself of every case in which during the year 1885 Dr. Imlach removed the uterine appendages on one or both sides—i.e., partial or complete spaying—for pelvic hæmatocele or hæmatosalpinx. This Annual Medical Report of the Hospital for Women, Shaw-street, Liverpool, for 1885, was written entirely by, or under the immediate direction of, Dr. Imlach, and must therefore be held to be a sufficient authority for the statements taken directly from it.

Thus it will be seen from Dr. Imlach's own Report, given in a tabular form, that the whole number of cases of pelvic hæmatocele and hæmatosalpinx in which the uterine appendages were removed during the year 1885 amounted to 9, of which 3 died and 6 recovered—a mortality of 33·3 per cent.

I am, Sir, yours truly,
September 8th, 1886. THOMAS F. GRIMSDALE.

COPIED FROM TABLE III. TO ANNUAL MEDICAL REPORT FOR 1885, HOSPITAL FOR WOMEN, LIVERPOOL.

THE SURGICAL REPORT ON THE BELFAST RIOTS.

To the Editor of THE LANCET.

SIR,—Kindly allow me space for a personal explanation. Commenting on the summary of my Report, you state it is your "impression that Mr. Foy under-estimates the number of those injured in the riots." Nothing was more difficult to avoid than exaggeration in preparing my report, which I may incidentally remark was for your contemporary, the *Medical Press*. I was told of hundreds killed, of many bodies buried in back yards, of dozens of insurance agents requested not to ask for medical certificates, of congregations that counted their losses by scores, &c. Of the wounded, if I had believed what I was told, the Shankhill-road fight was more terrible than Plevna. But I was not going to print loose statements, and as I was actually in one of the riots in the Shankhill-road, and read the following day's Belfast papers, I saw that the reports did not minimise the incidents of the night. The cemetery returns, the doctors' lists, the statement of the rector and curate of one of the largest congregations (one which was said to have suffered dreadfully), and the personal introduction into the disturbed districts of the most trusted men of both sides, were all utilised to aid me in forming an approximation to the truth. As for the statement that many bodies were buried in back yards to avoid medical certificates—a statement which is freely made by artisans in Belfast, and appears to be credited by many,—I think it is unwarranted. With most diligent searching I could not find a single such grave. As for the wounded, I only counted such cases as required surgical care. Of the 322 police "more or less injured," I do not hesitate to say that the "less" form the enormous majority.

I am, Sir, yours faithfully,

Dublin, Sept. 4th, 1886. GEORGE FOY.

To the Editor of THE LANCET.

SIR,—Permit me to point out an error into which you, in common with several newspapers, have fallen in ascribing this Report to the initiation of the Loyal and Patriotic Association. In your issue of Sept. 4th you quote largely from this Report, prefacing the same with the remark that it is "just presented by Mr. Foy, F.R.C.S., the surgical commissioner sent down by the Irish Loyal and Patriotic Union to inquire into the nature of the injuries," &c. Mr. Foy went solely as our special-commissioner, to report exclusively on behalf of the *Medical Press and Circular*, and was in no sense the commissioner for any political association; and his report appears in full in the above journal for Sept. 1st. The mistake probably arose from the fact of the Loyal and Patriotic Union having, with our permission, reprinted the report in pamphlet form and circulated it throughout the country. This correction has now been made in the House of Lords, during debate, and in *The Times* and several leading newspapers, and in justice to the *Medical Press and Circular*, I trust you will kindly allow this to appear in your columns.

I am, Sir, your obedient servant,

Sept. 1886. A. A. TINDALL, General Manager.

INFANT FEEDING.

To the Editor of THE LANCET.

SIR,—Dr. Thurstan publishes a paper in your issue of Sept. 4th on the above-named subject, in which he advocates the early use of farinaceous food in the hand-rearing of young babies. Physiology and experience both, in my opinion, negative such a plan. It is not to express this opinion that I write, but to refer to certain points in the paper which lead me to think that Dr. Thurstan's failure with cow's milk is to be explained by his method of using it. In the case quoted he states that a child recently born was fed upon "milk-and-water, half and half of each." Those accustomed to hand-rearing of infants would easily predicate what he tells us in detail afterwards. No baby certainly can be expected to tolerate milk food of such a strength at that age. Nothing is said as to the *interval* between the meals, or the *quantity* given at each meal. These two factors are of equal importance to the selection of food, and should not be ignored. The *manner* of giving the meals is also not stated. In this paper we also find that lime-water "sometimes produces sickness." How soon after the meal? Upon the answer to this question may possibly hang the solution to what, I cannot help thinking, is an error in reasoning upon the part of the observer. In the numbered diets "cream-and-water" is mentioned, and subsequently negatived for use because of the absence of caseine. Dr. Thurstan probably does not know of the admirable mixture of whey-cream-and-water (Eustace Smith), and, for after-use, of Frankland's milk. This latter preparation should at first be used, I think, more diluted with whey than Frankland suggests. The "problem we have to solve" is scarcely "how to make curd digestible," but in what way we can reduce the caseine to digestible limits in each individual case. That this can be done by one of the two methods mentioned by me is certain. Increasing experience makes me more convinced that the larger proportion of failures in the use of cow's milk is due to want of appreciation of the general principles of hand-rearing and the erratic manner in which it is given. At least an equal interest in the subject to that claimed by the writer of the paper makes me hope that Dr. Thurstan's suggestions may not be adopted.—I am, Sir, yours obediently,

LEWIS W. MARSHALL, M.D.,

Nottingham, Sept. 5th, 1886. House-Surgeon, Children's Hospital.

THE INTRA-UTERINE GALVANO-CAUTERY.

To the Editor of THE LANCET.

SIR,—In an annotation in your issue of Sept. 4th you refer to the use of the galvano-cautery in the treatment of dysmenorrhœa. I have no doubt that galvano-cautery, if applied to the cervical canal, will relieve the affection, and I should think that it would not be necessary to cauterise the entire intra-uterine wall; but a much easier and more effectual method of using electricity for the relief of the complaint named is electrolysis. This, I should say, has proved more effectual than any other method hitherto adopted. I will not enter into the question as to whether or not stenosis is the cause of the painful menstruation, but a common mode of treating the affection, even by opponents of the obstructive theory, is to dilate the os uteri. In the treatment by galvano-cautery to which you alluded, the os was first dilated, and it might be said that the relief experienced was due to the dilatation, and not to the electricity. With electrolysis no previous dilatation is necessary, and therefore the operation can be performed much more easily and without the slightest pain. No doubt after the operation the cervical canal is larger from the chemical action which takes place around the electrode. Very possibly, for the cases in which M. Apostoli is mentioned as using the galvano-cautery, it may be the best method of employing electricity. Of this I have not as yet had sufficient experience, but I am sure that for dysmenorrhœa and several other affections of the uterus for which electricity can be employed electrolysis will be found the most effectual and best form of using it.

I am, Sir, yours faithfully,

Welbeck-street, W., Sept. 1886. W. E. STRAVENSON, M.D.

ON CLERGYMAN'S SORE-THROAT.

To the Editor of THE LANCET.

SIR,—The theory propounded by Dr. Whipham with regard to one of the causes of the so-called clergyman's sore-throat, and published in THE LANCET of September 4th, will, I am sure, be acquiesced in by many who have had some of these troublesome cases to deal with; but there is another matter not mentioned by Dr. Whipham, which has certainly in more than one case under my care declared itself by contributing to the obstinacy of the attack—that is, the wearing of the stiff band-like collar now so much in use by clergymen. This I have found, when the head is bent, presses unduly across the thyroid cartilage, and at times a sharp red line on the skin may be observed after the performance of a service, showing how severe the pressure has been.

In a case lately under my care, by discarding the use of this kind of collar and wearing one open in front, more after the fashion of those which prevail amongst barristers, remedies succeeded which had hitherto failed.

I am, Sir, yours truly,

Windsor, Sept. 1886. W. B. HOLDERNESS.

INFECTIOUS PNEUMONIA IN THE VALLEY OF THE BLACKWATER.

To the Editor of THE LANCET.

SIR,—To illustrate the insanitary condition of the Blackwater valley between Farnborough and Sandhurst, I would mention the case of the family of the tenant of Ivy Cottage, Farnborough. This cottage is situated in the valley, on the estate of the Empress Eugénie, far away from any other habitation. The family were attacked with diphtheria last year. This year the mother got an ordinary cold, which rapidly developed into epidemic pneumonia, and, being weakened by a miscarriage, she died. The husband and *five* of the children have been dangerously ill with the same disease, which, so far as my experience goes, is one of very rare occurrence, never appearing except in malarious damp districts. I look upon these cases as further confirmation of the necessity for cleansing the Blackwater river at Farnborough and Sandhurst.

I am, Sir, yours obediently,
C. J. DENNY, M.D.,
Medical Officer of Health for the Adjacent District.
Milestone House, Blackwater, Farnboro' Station, March 2nd, 1886.

ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

To the Editor of THE LANCET.

SIR,—At page 486 of your issue of Sept. 11th, in your notice of the Army, Navy, and Indian Medical Services, you state—"On its conclusion the surgeon on probation is gazetted to the Medical Staff or Indian Medical Service as Surgeon, with the relative rank of Captain; in the Navy the successful candidate is at once gazetted as a Surgeon." Surely you are aware that the surgeon who is a candidate for the Medical Staff is placed in a position junior and inferior to both the Navy and Indian, for in the Navy, as you say, men receive a commission at once, and in the Indian the commission bears date several months earlier than the commission of the men of the Medical Staff, so that the men who pass last in the competitive examination in London for the Navy and Indian Medical Services are senior in the Service, and remain so all their lives, to the man who passes first for the Medical Staff. If, Sir, you are not aware of this, I would refer you to the Army List; and if you are aware of it, would it not be advisable to correct the very wrong impression your notice must convey to the student who cannot understand "how these things can be." Possibly the appeal in Parliament to the Secretary of State for War to give up the cheeseparing policy as regards the Medical Staff may alter this before the next Students' Number appears.

I am, Sir, yours obediently,
September, 1886. NOUS VERRONS.

MANCHESTER.

(From our own Correspondent.)

THE SALFORD HOSPITAL.

THE extension of the Salford Hospital is rapidly approaching completion; the out-patient and accident rooms are very conveniently arranged, and exceedingly well adapted for their purposes. It is in contemplation eventually to have special departments in the institution for ophthalmic and obstetric work, &c., and accommodation is provided for the expected attendance of some of our students. Hitherto the number of beds has been below that required for recognition by the College of Surgeons, but with the extensive alterations now completing provision will be made for some 120 beds, and very probably in the near future it may become a formidable rival to the Royal Infirmary as a clinical hospital for the teaching of medical studen[ts]. The whole of the additional buildings have been er[ected] without appealing to the public for funds, these h[ave] been obtained by a bequest from the late Mr. J. Pend[lebury] having

THE VOLUNTEER MEDICAL STAFF CORPS.

This corps, which was inaugurated here some fe[w] ago, has attained a fair measure of success. [The] company is advancing towards completion, [the] months being quite efficient, and furnished with uniform[s]. The first public are asked to supply funds for the e[quipment] one squad [of] Medica[l] port of this assertio[n] [do] not [fi]t, &c. The equipment of the whole of the company, in order that it may be handed over to the Government and share in the annual Government grant.

SUNDAY LECTURES.

The fifth course of "Sunday afternoon lectures" to the people was commenced last Sunday in Ancoats, one of the poorest and most crowded parts of Manchester, by Mr. A. H Acland, M.P., who selected as his subject the "Love of Liberty." Hitherto these Sunday afternoons have been a great success, and this year's series promises to be still more successful. Many eminent and well-known names are amongst the future lecturers—the Dean of Manchester, Sir Henry Roscoe, M.P., several of the professors of Owens College, Mr. William Morris, the Hon. Auberon Herbert, Mr. Councillor Southern, Mrs. Fawcett, and many others. These attempts to bring some light and learning amongst the masses of our artisan and labouring poor deserve every encouragement and support.

COFFEE *versus* BEER.

At the recent City Brewster Sessions applications were made by several innkeepers in the neighbourhood of Shudehill Market for leave to open their houses at four o'clock in the morning. The Markets Committee have provided coffee stalls specially for the use of market people in the early morning, and the magistrates wisely refused all the applications, notwithstanding the arguments put forward "that hard-working men required something stronger in the morning than coffee." When will the lesson be learnt that alcoholic drinks afford neither strength nor nourishment.

Manchester, Sept. 7th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE HEALTH OF TYNESIDE.

THERE has been a marked deterioration in the state of public health here during the past few weeks. There were no fewer than fifty-seven cases of infectious disease during the fortnight ending August 28th, as appears from the reports of practitioners in the borough of Newcastle to the medical officer of health. Of this large number, thirty-eight were of scarlet fever. There was also one case of small-pox, and five persons were attacked with diphtheria. Diarrhœa also has been very prevalent and fatal in the cases of infants. In the sister borough of Gateshead there has been a very serious outbreak of the latter affection, mostly occurring amongst the children of the poor in the various towns on the Tyne. Dr. Monro, medical officer of health for South Shields, pointed out in reference to the prevalence of diarrhœa, that there had not been a single death of an infant fed by the breast. At Gateshead, at the last meeting of the Town Council, a common cause of diarrhœa and other intestinal affections was said to be the custom of fruiterers and grocers sweeping their damaged fruit into the streets, and leaving it there until the scavenger's cart came round; but in the meantime the refuse was picked up and eaten by the children.

A CURIOUS DEFENCE.

At a late sitting of the Middlesbrough County Court, Dr. M'Cuaig sued a man for one guinea for professional services. It was shown that some time since the defendant took laudanum, and the doctor was called in by defendant's housekeeper, who was also his niece. He was duly attended by Dr. M'Cuaig, and after having been walked about for five hours and after having been pay the doctor his [illegible] hours he recovered, but refused to him. His uterine [illegible] fee on the plea that he did not send for

Removal of uterine [illegible] Honour: "Did you wish to be left to die?" Defendant: "I did not want the doctor." His Honour: "You Removal: will have to pay or go to prison." Defendant: "I won't pay it at all." His Honour ordered defendant to pay 3s. per month, and the judgment does not certainly seem to be a severe one. A case like this is just the one to give a medical man a great deal of trouble. He goes at once, to the detriment of other practice, and perhaps is detained many hours in an endeavour to save life, and has to sue for his fee.

SUNDERLAND INFIRMARY.

The new wing which it is proposed to erect to the memory of the late Mr. James Hartley, I understand, is to be devoted to children, and for this purpose some arrangement, it

is stated, will be made to effect a combination with the Sunderland Hospital for Sick Children, which has been established for many years in Lambton-street, and which has proved such a benefit to the sick poor of Sunderland and its district. The cost of the wing is estimated to be between £8000 and £9000.

A very serious epidemic of scarlet fever is reported as prevailing at Blackdean in Weardale.

Newcastle-on-Tyne, Sept. 13th.

ABERDEEN.

(From our own Correspondent.)

THE ABERDEEN ROYAL INFIRMARY.

THE quarterly Court of Managers of the Royal Infirmary met on Monday, the 13th inst., and the sitting was chiefly occupied with matters relating to the medical staff. For the office of assistant-physician, which fell to be filled up at this meeting, there were four candidates—viz., Drs. M'Kenzie Booth, MacGregor, Rodger, and Smith. Three votes were taken before an absolute majority was obtained for the successful candidate. As the result of the first vote, Dr. MacGregor's name was struck off the list, and the final vote lay between Dr. Rodger and Dr. Smith. The latter was elected by 113 votes, against 77 given for Dr. Rodger.

Dr. Struthers then brought forward his motion: "That all the members of the medical staff be appointed by the executive, and hold office during the pleasure of the executive; that the limit of service for the visiting medical officers be restricted to fifteen years, except in the case of professors in the University engaged in clinical and pathological teaching whose services the executive may deem it expedient to continue." An amendment, practically a direct negative, was carried by a majority.

THE PROPOSED NEW CHARTER.

The court approved of the constitution embodied in the draft of the proposed new Charter as revised by the managing committee, and remitted to the committee to take all necessary steps for carrying it into effect either by obtaining a new Charter or by private Act of Parliament. A new Charter costs £700, and the estimated cost of a new Bill is £400. This is a serious matter for an institution already beset with financial difficulties. A considerable sum has been spent on the alterations of the present buildings, for their report on the sanitary condition of which, it seems, Dr. Russell of Glasgow received £52 10s., and Dr. Simpson, then medical officer of health for the city, £21. Mr. Esslemont protested against so large a sum, £73 10s., being paid to those gentlemen out of the funds of a charitable institution.

EXTENSION OF THE HOSPITAL.

The Committee of Management are still deliberating upon the plans for the extension of the infirmary buildings, and the dissatisfaction felt at the delay found expression in the motion proposed by a manager, "that the Court enjoin on the Committee of Management the necessity of coming to a speedy resolution, and presenting their final report on the matter of the hospital buildings."

Aberdeen, September 11th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

AN account of the expenditure of this University recently issued shows that for the year ending March last the salaries of the Fellows amounted to £7765, and the travelling expenses of examiners and superintendents to £1125 As contrasted with these figures, the sum awarded in scholarships amounted to only £776, and in studentships to £475. A sum of £750 was allocated for the travelling expenses of members of the Senate; and in reference to this item, the Comptroller-General of the Receipt and Issue of Her Majesty's Exchequer states that, in answer to a letter from his department asking under what authority such expenditure was incurred, the accounting officer replied that the Standing Committee of the Senate held that they had powers under the charter and statutes founded upon the provisions of the Act 42 and 43 Vic., c. 65, to incur such expenditure. The authorities referred to in the opinion of the Auditor-General of Public Accounts do not contemplate expenditure of this character. The item referred to (£750) was for the travelling expenses of members of the committee appointed by the Senate to obtain for the Royal University of Ireland a representative in Parliament.

QUEEN'S COLLEGE, GALWAY.

The President, in his report for the past session, regrets that year by year the number of students at his College has shown a decided decrease; last year they numbered only 94, of whom 34 attended the classes in the Faculty of Medicine. In the session 1881-82 the number was 201, and for a diminution so sudden and rapid he finds an adequate cause in the dissolution of the University organisation, of which the Queen's Colleges formed a part; for the Queen's Colleges and University, though apparently distinct institutions having separate charters from the Crown, really formed but one organised whole. The library and museums are in a satisfactory condition, and the apparatus for the illustration of the principles of natural philosophy, and the collections specially devoted to the pursuits of the medical profession, are worthy of special notice. Large additions have been made to the Natural History Museum, but a conservatory for the preservation of such plants as are requisite for properly illustrating the botanical lectures is still wanting. A new room, or an extension of the anatomical room, is urgently required for histological and microscopical researches; and the President trusts that the rapid development of medical science, especially in the biological department, and its immense practical importance, will justify the solicitation that this pressing need will receive immediate attention from the Board of Works.

ADDRESS AND PRESENTATION TO MR. C. NORMAN, F.R.C.S.I.

An address was last week presented to this gentleman, who has been recently promoted from Monaghan Lunatic Asylum to the important post of resident medical superintendent of the Richmond District Lunatic Asylum. The address was given by some of his friends in Monaghan, joined by the officials of the asylum, and, in addition to the address, he was presented with a magnificent centre-piece and a claret jug.

"WAKING" THE DEAD.

At the Dublin Police-court, last week, a most revolting case of this barbarous custom was detailed. A child had died, and over its body a "wake" had been held for ten successive nights. The body, which was far advanced in decomposition, was, according to the evidence, lying on the bare boards, while night after night a mob of persons assembled, drinking, fighting, and gambling. The magistrate made a compulsory order for burial, otherwise most probably the body would not have been interred for many days afterwards.

A CENTENARIAN.

A man named Holland died a few days since in the North Dublin Union Workhouse at the alleged age of 105 years. About three months previously to his death he was attacked with pneumonia of a serious character, but recovered. His death was due to a severe attack of choleraic diarrhœa. It may be mentioned that the deceased was an inveterate smoker and used the strongest tobacco.

Dr. J. O'Callaghan, medical officer of Johnston dispensary district, has been unanimously elected medical officer of Dunmanway Union Workhouse.

Mr. Werner has been appointed ophthalmic surgeon to the Mater Misericordiæ Hospital.

The late Mr. Archibald Gardiner has left, after the death of his wife, £500 to the Belfast Royal Hospital.

HARROGATE BATH HOSPITAL AND CONVALESCENT HOME.—The foundation-stone of the new building in connexion with this institution was laid on the 9th inst. The Bath Hospital will afford accommodation for seventy-five patients, and the Convalescent Home for fifty inmates. The estimated cost is £17,000, of which £15,300 has already been subscribed. Owing, however, to the sloping nature of the ground and the fact that the danger of interfering with the springs has necessitated extensions of the original designs, the estimated cost will probably be somewhat exceeded.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon Edward Hawke Locker has resigned his commission.

INDIA OFFICE.—The Queen has approved of the following promotions among the officers of the Staff Corps and Indian Military Forces, made by the Governments in India:—Brigade Surgeon James Howard Thornton, C.B., of the Bengal Medical Establishment, to be Deputy Surgeon-General; Surgeons-Major Henri Jules Blanc, M.D., and William Dymock, of the Bombay Medical Establishment, to be Brigade Surgeons.

ADMIRALTY.—The following appointments have been made:—Surgeon James Clibborn, to the *Indus;* Surgeon Charles James, to the Plymouth Division Royal Marines; Surgeon William S. Lightfoot, to the *Téméraire;* Surgeon Bowen S. Thends, to the Haslar Hospital; Surgeon Horatio S. R. Sparrow, to the *Victor Emanuel;* Surgeon George F. Dean, to the *Polyphemus;* and Surgeon William W. Pryn, to the *Hotspur.*

ENGINEER VOLUNTEERS.—1st Newcastle-on-Tyne and Durham: Richard Knox Tait, Gent, to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Royal Fusiliers (City of London Regiment): Henry Geo. Thompson, Gent., M.D., to be Acting Surgeon.—2nd Volunteer Battalion, the Worcestershire Regiment: Surgeon W. S. Batten, the resignation of whose commission has already been announced, is granted the honorary rank of Surgeon-Major, and is permitted to wear the uniform of the battalion on his retirement.

MEDICAL NOTES IN PARLIAMENT.

Honorary Surgeons in India.

IN the House of Commons on the 9th inst., MR. LAWSON asked the Under-Secretary of State for India whether he was aware that under a Government resolution, dated Bombay, Jan. 12th, 1881, it was ruled that no more medical subordinates would be promoted to honorary commissions unless they had obtained medical diplomas; that three warrant medical officers came to England under this rule, and, after much study and expense, obtained English medical diplomas, and that on their return to India the rule was abrogated by the decision that no further promotions would be made to the rank of honorary surgeon; and whether, considering the circumstances under which they acted, he would take steps to procure their promotion to the honorary commissioned rank under the rule of Jan. 1881.—Sir J. Gorst, in reply, stated that in 1884, on a reorganisation of the subordinate medical establishment, the selection of warrant officers for the post of honorary surgeons was put an end to on public grounds; but, instead, certain other privileges were conferred on the department to which the warrant officers belong. There was, in the opinion of the Secretary of State, no reason for making an exception in the case of the three officers referred to.

The Asylums Board.

In reply to Mr. Pickersgill, Mr. Ritchie stated, with regard to the representation of the Metropolitan Union on the Asylums Board, that an order had been issued increasing the number of elected managers by nine. Information as to the expenditure of the Asylums Board was already furnished by the managers to the guardians, and, prior to each half-yearly audit, the ledger accounts of the managers were open to the inspection of any ratepayer or owner of property in the metropolis.

Belfast Royal Hospital.

Mr. Sexton called attention to the claim of the Belfast Royal Hospital to a grant from the Treasury owing to the extraordinary demands made upon the institution as a result of the recent riots. The Chancellor of the Exchequer said that he would, in consultation with the Chief Secretary and the Attorney-General for Ireland, go carefully into the circumstances of the case; and if it were the opinion of the authorities in Ireland that a special grant should be made from the Treasury to this hospital on account of the expense it was put to in consequence of the riots, he, as Chancellor of the Exchequer, should throw no difficulty in the way of that being done.

On the 13th inst. Sir Michael Hicks-Beach, in reply to a further question from Mr. Sexton, stated that, as present advised, he did not think it would be right to recommend that Belfast and this hospital should be treated exceptionally by getting a Government grant for treating those injured in the riots. There might be a case for such a grant if the constabulary or military had been treated at the hospital, and he would inquire into this point.

The Pollution of the Thames.

In reply to Mr. Lawrence, who asked what steps the Metropolitan Board of Works were taking to remedy the nuisance arising from the pollution of the river Thames by the main drainage outfalls, Mr. Matthews stated that he could not, within the compass of an answer to a question, detail the scientific processes which were being carried out, and which would, it was confidently believed, be found sufficient to prevent the pollution of the river.

Proficiency Certificates in Vaccination.

On the 10th inst., Mr. Ritchie, in reply to Dr. Tanner, stated that the certificates of proficiency in vaccination required as part of the qualification for the appointment of public vaccinator in England could only be obtained at certain educational vaccination stations, which were subject to the inspection of the Local Government Board. Twenty public vaccinators in Great Britain had been authorised to grant such certificates; the stations being at London, Birmingham, Bristol, Exeter, Leeds, Liverpool, Manchester, Newcastle, Sheffield, Edinburgh, and Glasgow. The Board had in the present year been applied to to authorise the grant of such certificates at Dublin, and had expressed their willingness to do so upon certain arrangements being made in order to assimilate the practice with regard to the issue of certificates throughout the United Kingdom. Steps were now being taken for this purpose.

Later in the evening, during the consideration of the Civil Service Estimates, on the vote to complete a certain sum for the Local Government Board, Mr. A. O'Connor, after protesting against the practice of vaccination as inimical to the welfare of the community, proposed to move the reduction of the vote by the sum of £16,500, the amount appropriated in the vote to the payment of vaccination officers. After some remarks by Mr. Ritchie, Dr. Tanner, and others, the amendment was negatived without a division.

The Lunacy Laws.

On the 13th inst., in answer to Mr. Corbet, Mr. Matthews confirmed the previously announced intention of the Government to proceed with legislation on the subject of lunacy. It would be a matter for consideration whether this legislation should extend to Ireland and Scotland.

House-boats.

On Thursday, in reply to Mr. H. S. Wright Mr. Ritchie said the Thames Conservators were empowered under an Act of last year to make regulations for the prevention of the pollution of the river by steam launches or house-boats. They had prepared a bye-law which would render liable to a penalty any person who polluted the river by dropping into it offensive matter. This bye-law, with others, had received the approval of the Queen in Council. In answer to another question by Mr. Wright, the Chancellor of the Exchequer replied that house-boats on the river were not liable to Imperial taxation, and it was not proposed to impose any tax upon them, because the amount which would be collected would be insignificant. Under the bye-laws of the Thames Conservancy, however, it was intended to charge registration fees for house-boats.

SANITARY CONGRESS.—The annual Congress of the Sanitary Institute of Great Britain will be held this year at York under circumstances promising well for its success. The President of the Congress, which will open on the 21st inst., is Sir T. Spencer Wells, and the list of Vice-Presidents includes the names of Dr. Richardson, Dr. G. Buchanan, Sir J. Fayrer, Miss Nightingale, and Professor Humphry, of Cambridge. Sir T. Spencer Wells will give an address, and the sections, which are only three in number, will be—first, under Dr. De Chaumont, "Sanitary Science and Preventive Medicine"; second, under Mr. Baldwin Latham, assisted by Mr. E. C. Robins, "Engineering and Architecture"; and, third, under Mr. W. Whitaker, assisted by Mr. G. J. Symons, "Chemistry, Meteorology, and Geology."

Obituary.

ROBERT FOWLER, M.D., M.R.C.P. ED., M.R.C.S. ENG., &c.

ON August 7th there passed away from the medical profession in London Dr. Robert Fowler, of Old Burlington-street, W., and of Bishopsgate-street, City. Born in Belvidere-road, Lambeth, in the year 1828, and educated first at Merchant Taylors' School and then at the Grammar School, Cardigan, under the present Archdeacon Griffiths of Llandaff, Dr. Fowler was, on leaving school, placed as an apprentice with the late W. M. Noot, Surgeon, of Cardigan. Completing his apprenticeship, he entered as a medical student at King's College Hospital. Here, after due course, he obtained the Associateship of the College, and qualified M.R.C.S. and L.S.A. He then proceeded to Edinburgh University, where in the year 1851 he graduated M.D. After leaving Edinburgh he accepted the post of house-surgeon at Loughborough Infirmary; but after honourably fulfilling the duties for a time he left the infirmary and came to London. Settling in Bishopsgate, City, in the year 1854, although he was then but twenty-six years of age, he soon acquired an extensive and lucrative practice. For many years he held the post of medical officer to the East London Union; but, on the amalgamation of the three Unions into the combined City of London Union, he retired on a pension. Elected soon after a guardian of this union, he held his seat on the board till his death. He always took great interest in Poor-law medical relief, and at one time wrote extensively on the whole subject of Poor-law medical reform. He gave extensive evidence before the Commons' Select Committee on Poor-law Relief, and by so doing he was very materially instrumental in the passing of Hardy's Act. In 1879 he was elected by the City of London Union one of their managers on the Metropolitan Asylums Board. Here he soon distinguished himself for useful work, and on the occasion of the recent scandals in the management of the Homerton Fever Hospital he was very active in promoting the inquiry. Eleven years ago he was elected an examiner of the Society of Apothecaries, and, with the exception of one year, was re-elected every year since. For some time he held the post of librarian to the Hunterian Society, and to him the Society are indebted for the catalogue of their library. In the year 1882 he was selected the Society's Orator, and the oration which he delivered was so able and interesting that, in deference to a widespread request, it was afterwards published in the form of a pamphlet. The title of the oration is, "The Attributes, Professional and Social, of the so-called 'Family Doctor,'" and the author of it was so highly esteemed by the members of the Society that the following year he was elected their president.

Dr. Fowler was so active and industrious, and so desirous of doing good, that during the whole of his career he never allowed any opportunity to pass of performing a public service. In 1870, by a long letter to *The Times*, he drew attention to the celebrated case of the Welsh Fasting Girl, and having made himself thoroughly acquainted with every detail, he published a comprehensive volume on the whole case. The full title of the work is, "A Complete History of the Welsh Fasting Girl, with comments thereon; and observations on Death from Starvation." The work is chiefly interesting to the practitioner of medicine on account of its scientific worth—that is to say, by reason of Dr. Fowler's discussion of the subject of starvation in general; but even to the ordinary reader his remarks are so clear and obvious, that few such persons taking up the work would omit to read his observations on death from starvation.

Dr. Fowler was the author of a Medical Vocabulary, a work which has already reached a second edition. The task, however, will be in due time taken up and completed by his son. In addition to his ordinary literary work, he at one time tried his hand at poetry; and the amusing poem headed "The Parish Leech," and published some years ago under the *nom de plume* of "A Parish Doctor," was really from his pen. His contributions to the medical journals were varied and numerous, and for a long series of years he was an occasional contributor to the columns of this journal. His last literary effort was an interesting illustrated article entitled "On the Discovery of one of the 'Seites' set apart in Whitechapel for a Pest-ground, *temp.* Edward III.," which was published in THE LANCET about a year ago, and afterwards republished in pamphlet form.

CHARLES CHADWICK, M.D., F.R.C.P. LOND.

DR. CHADWICK, whose death occurred somewhat suddenly at Buxton on the 30th ult., was born at Leeds in 1815. He received the major part of his medical education in Edinburgh, and in 1837 took the degree of Doctor of Medicine at the University of that city, becoming a Fellow of the Royal College of Physicians of Edinburgh in 1845, and a Fellow of the Royal College of Physicians of London in 1866. Settling down to practice in his native town, Dr. Chadwick soon attracted attention, and whilst comparatively young was elected physician to the Leeds General Infirmary, an office which he retained for nearly eight years. At the same time he held various lectureships in connexion with the Leeds School of Medicine, an institution in whose welfare and prosperity he took a lively and active interest. To Dr. Chadwick's exertions, too, Leeds is mainly indebted for the hospital which at the present time adorns the town. In the West Riding Medical Charitable Society Dr. Chadwick took a great interest, and of it he was for many years the chief director. He found no labour too great to bestow upon it, and he contributed largely to its funds in money, as well as in time and labour; and when, in consequence of failing health, he was compelled to retire from its active management, the members, in recognition of his services and as a token of their regard, presented him with a substantial gift of silver plate. Dr. Chadwick was president of the British Medical Association in 1869, when the annual meeting was held in Leeds, and afterwards became a vice-president of that body. He was a Justice of the Peace for both the borough of Leeds and for the West Riding of the county of York, and he was also one of the twenty-five patrons of the parish church of Leeds. Some twelve years ago, when removal from Leeds was necessitated by failing health, he took up his residence at Tunbridge Wells, and, although he was known to be suffering from diabetes, the news of his death came upon his friends as a surprise, as in a recent visit to the north of England he manifested a degree of robustness which encouraged the hope that his life might have been prolonged for some time.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 2nd inst.:—

Gibbon, Ernest Henry, Marlborough House, Seaham.
Gillmon, John Charles, Oxonian-street, East Dulwich Grove.
Gregory, Seth, Birchanger-road, South Norwood.
Hughes, Hugh Lewis, Bridge-street, Llanbadarn, Aberystwyth.
Todd, Henry, Mile-end-road.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Goodwin, William Henry Frederic, Westminster Hospital.
Lewington, John Joseph, London Hospital.
McGeagh, William Stewart, St. Thomas's Hospital.

The following gentlemen passed and received certificates to practise, on Thursday, the 9th inst.:—

Brooks, Richard Philip, Tollington-park.
Griffiths, William, St. John's Wood Terrace.
Marks, Robert John, Canyage-square, Clifton, Bristol.
Melland, Brian, Victoria-park, Manchester.
Rusher, John Golby, Pershore, Worcestershire.
Wright, Charles Franklin, Trafalgar-road, Great Yarmouth.

THE annual sermons on behalf of the local infirmary were preached at Bridgwater on the 12th inst.

THE Municipal Council of Milan has contributed the sum of £400 to the Pasteur International Institute.

THE Sanitary Committee of the Bolton Corporation have decided to invite the members of the Sanitary Institute to hold their annual congress at Bolton next year.

AT a meeting of the City Commission of Sewers on the 14th inst., Dr. Sedgwick Saunders, the medical officer of health, stated that the deplorable state of the river Thames near Purfleet arose through the experiments in deodorising sewage now being made by the Metropolitan Board of Works, which experiments, in his opinion, were worse than useless, and were only serving to lull the public into false security. Some eight million gallons of sewage out of the 160 millions daily discharged into the river are being experimented on at, it is reported, a cost of £3000 per week.

THE MAYORALTY OF WOLVERHAMPTON for the ensuing jubilee year has been offered by resolution of the Borough Council to Mr. Vincent Jackson, F.R.C.S.E., surgeon to the Staffordshire General Hospital, who has written to the present Mayor accepting the nomination.

SHEFFIELD SCHOOL OF MEDICINE.—The Winter Session 1886-7 will commence on Friday, October 1st, at 5 P.M., when the introductory lecture will be delivered in Firth College by Dr. W. S. Porter, physician to the Public Hospital and Dispensary and lecturer on Physiology. The prospectus and all information may be obtained from Arthur Jackson, secretary.

A PARKES MUSEUM FOR PARIS.—The Paris Municipal Council have decided to open a Hygienic Museum, in which the microscopic effects of allowing water to stagnate, the skin to remain dirty, and bad air on the blood will be shown, as well as other causes of disease. Lectures on the laws of health will be delivered in connexion with the exhibition.

BUTTER SUBSTITUTES.—The Bill to amend the law relating to the trade in butter substitutes, brought into the House of Commons by Sir Joseph McKenna, imposes a maximum penalty of £20, or one month's imprisonment, on any person importing, manufacturing, or offering for sale, margarine or oleomargarine without due branding of the name on all packages. The penalty is increased to £50, or six months' imprisonment, for a second offence. Margarine or oleomargarine factories are to be registered and inspected.

PRESENTATION.—At the half-yearly meeting of the governors of the Wolverhampton and Staffordshire Hospital on the 14th inst., Dr. Millington, who until recently held the position of senior honorary physician, was presented with a life-size portrait of himself, painted in oil, a silver salver, and tea and coffee service, in testimony of the valuable services he had rendered to the institution for the long period of thirty-two years. It has been arranged that the portrait shall be hung in the board-room of the hospital.

THE DISPOSAL OF TOWN REFUSE.—On the 14th inst. the members of the Preston Town Council inspected a refuse destructor which has just been erected in that town at a cost of £6387 exclusive of the site, the purchase-money of which was £12,000. The destructor consists of eight furnaces, each of which will consume seven tons of refuse in twenty-four hours. The furnaces have been in operation a few days, and the inspection was considered to be perfectly satisfactory.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of the members of this Association on the 9th inst., Dr. Vacher, the medical officer of health for Birkenhead, read a paper entitled "When Infectiousness begins and when it ends in Scarlatina, Measles, Small-pox, Mumps, and Diphtheria." With regard to the first point, Dr. Vacher pointed out that there was danger from infection from the moment the patient became infected, and, as to the time when the infectiousness terminated, that this was determined by the time it took for the complete elimination of the morbid products thrown off by the patients.

PARKES MUSEUM.—During next month the following lectures and demonstrations will be delivered at Margaret-street, Regent-street:—October 4th: Introductory lecture on General History, Principles and Methods of Hygiene, by Dr. G. V. Poore. 6th: Water-supply, Drinking-water, and Pollution of Water, by Professor Corfield. 8th: Drainage-construction, by Professor H. Robinson. 11th: Sanitary Appliances, by Mr. Gordon Smith. 13th: Ventilation, Measurement of Cubic Space, &c, by Professor F. De Chaumont. 15th: Scavenging and Disposal of Refuse, by Mr. Percy Boulnois. 18th: Food (good and bad), Milk, Sale of Food and Drugs Act, by Mr. C. E. Cassal. 20th: Infectious Diseases and Methods of Disinfection, by Dr. R. Thorne Thorne. 22nd: General Powers and Duties of Inspectors of Nuisances (Method of Inspection), by Mr. J. F. J. Sykes. 25th: Nature of Nuisances, including Nuisances the abatement of which is difficult, by Mr. J. F. J. Sykes. 27th: Sanitary Law—General Enactments, Public Health Act, 1875, Model Bye-laws, by Dr. Charles Kelly. 29th: Metropolitan Acts, Bye-laws of Metropolitan Board of Works, by Mr. A. Wynter Blyth.

BRIDGE-END ASYLUM.—At the meeting of the Merthyr Board of Guardians on the 11th inst. attention was called to the fact that, although the majority of the 800 patients at the county asylum at Bridge-end were Welsh, and a number of these were unable to understand English, none of the medical officers understood Welsh. Owing to this circumstance, it was hinted that patients remained longer in the institution than was necessary, and it was unanimously resolved, in view of the erection of a new asylum building at a cost of £100,000, that it is desirable that officials conversant with both the English and Welsh languages be engaged.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

COTTERELL, EDWARD, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer to the Stoke Lyne District of the Bicester Union.

EVANS, C. W., M.B.Lond., M.R.C.S., has been appointed Visiting Medical Officer to the Bakewell Union Workhouse, vice Chas. Evans, deceased; and Certifying Surgeon, under Factories and Workshops Act, for Bakewell District.

FERRIER, DAVID, M.D., F.R.S., Professor and Physician at King's College Hospital and the National Hospital for the Paralysed and Epileptic, has been appointed Physician to the British Home for Incurables, Clapham.

KINGDON, E. C., M.B., C.M.Edin., late Assistant Medical Officer to the Middlesex County Asylum at Colney Hatch, has been appointed Assistant House-Surgeon to the General Hospital, Nottingham.

LOWRY, J. H., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, Imperial Maritime Customs, Pakhoi, China, has been appointed Medical Officer, Imperial Maritime Customs, Kiungchow, Hainan, China, vice Dr. E. A. Aldridge, transferred to Wuku.

PAGET, CHARLES E., M.R.C.S., L.R.C.P.Lond., has been reappointed Medical Officer of Health for the Westmoreland Combined Sanitary District, for a second term of three years.

PAYNE, WILLIAM ARTHUR, B.A.Oxon., M.R.C.S., L.S.A., has been elected House-Surgeon to the Richmond Hospital, Surrey, vice John Williamson, M.B., resigned.

SMITH, PATRICK BLAIKIE, M.D., C.M.Aber., has been appointed Assistant Physician to the Aberdeen Royal Infirmary.

SWANN, ALFRED, M.D., M.R.C.S., &c., has been appointed Certifying Factory Surgeon for the Batley District, vice Stockwell, deceased.

TROUTON, GARDINER, M.B., B.Ch.Univ.Dub., has been appointed House-Surgeon to the Cumberland Infirmary, vice G. Francis Smith, M.R.C.S., L.R.C.P., resigned.

WILLIAMS-FREEMAN, JOHN P., M.B.Dur., M.R.C.S., L.S.A., has been appointed House-Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital.

Births, Marriages, and Deaths.

BIRTHS.

BOSWELL.—At Saffron Walden, Essex, the wife of Henry St. George Boswell, M.B., C.M., of a daughter.

BROCK.—On July 7th, at Urlar, Rouxville, Orange Free State, the wife of George Sandison Brock, M.R.Ed., C.M., of a son.

CANE.—On the 7th inst., at The Gables, Belvedere, Kent, the wife of Howard Cane, M.D., L.R.C.P.Lond., of a son.

DONALD.—On the 28th ult., at Ambleside-avenue, Streatham, S.W., the wife of David Donald, M.D., C.M., of a daughter.

EDGAR.—On the 5th inst., at Settle, the wife of James W. Edgar, M.D., (prematurely), of a son.

FINLAY.—On the 3rd inst., at Lower Berkeley-street, Portman-square, W., the wife of David W. Finlay, M.D., F.R.C.P., of a daughter.

GALLOWAY.—On the 4th inst., at Epping, the wife of Arthur Wilton Galloway, M.R.C.S., L.R.C.P.Lond., of a son.

MURPHY.—On the 7th inst., at Holly House, Sunderland, the wife of Dr. Murphy, of a daughter.

NORRY.—On the 3rd inst., at Telford-park, Streatham-hill, S.W., the wife of William Augustus Norry, M.B., M.R.C.S., of a daughter.

OLIVER.—On the 8th inst., at Consett Hall, co. Durham, the wife of Thomas Oliver, M.D., of Eldon-square, Newcastle-upon-Tyne, of a son.

OWEN.—On the 11th inst., at Wattham's Dene, Twyford, Berks, the wife of Owen Owen, Brigade-Surgeon, retired, of a daughter.

POTTS.—On the 12th inst., at Vicarage-villas, Willesden, N.W., the wife of W. A. Beevor Potts, M.R.C.S., L.S.A., of a daughter.

SHANN.—On the 6th inst., at Micklegate, York, the wife of Henry Chas. Shann, M.R.C.S., of a son.

SHAPTER.—On the 7th inst., at Barnfield-crescent, Exeter, the wife of Lewis Shapter, M.D., of a son.

SPENCER.—On the 12th inst., at Albion-road, Stoke Newington, the wife of E. R. Spencer, M.R.C.S., L.R.C.P., of a son.

STOKES.—On the 8th inst., at Rose Park Lodge, Upper Tooting, S.W., the wife of F. A. Stokes, L.R.C.P., M.R.C.S., of twins (boys).

WALKER.—On the 10th inst., at Hurworth-on-Tees, the wife of Charles Edward Walker, M.B., M.R.C.S., of a son.

WORNUM.—On the 13th inst., at 6, College-terrace, Belsize-park, Hampstead, N.W., the wife of George Porter Wornum, M.R.C.S.Eng., of a daughter.

MARRIAGES.

BULL—GARDE.—On the 7th inst., at St. Mary's, Shenley Mansel, by the Rev. John Wood, Vicar of Old Wolverton (Rural Dean), William H. Bull, F.R.C.S., of St. Oswald's House, Stony Stratford, second son of W. J. Bull, Solicitor, of Oswestry, to Emma E. Cherry Garde, youngest daughter of the late Edward Hoare Garde, Esq., of Balunacurra House, co. Cork, and sister of the Rev. J. H. Garde, Rector of Shenley Mansel, Bucks.

JAMPBELL—HIRST.—On the 9th inst., at St. Chad's, Saddleworth, Colin George Campbell, M.R.C.S., of Uppermill, Saddleworth, to Annie Ethel, only daughter of Ben Hirst, of Tamewater House, Saddleworth, Yorkshire.

COLLINS—COPELAND.—At St. Mary's Church, West Rainton, by the Ven. Archdeacon of Durham, assisted by the Rev. Hugh McNeile Minton-Senhouse, M.A., brother-in-law of the bride, Surgeon M. J. Collins, R.W.I.M.S., eldest son of the late M. J. Collins, Solicitor, of Cork, to Esther, fourth daughter of the Rev. G. D. Copeland, B.D., Rector of W. Rainton, Durham.

DAVISON—VIVANCO.—On July 24th, at St. John's Church, Buenos Ayres, by the Right Rev. the Bishop of the Falklands, assisted by the Rev. Austin West, M.A., Rector of St. John's, and by the Rev. Lennox Robertson, M.A., James Thomas Richard Davison, M.D., youngest son of the late Robert Davison, Esq., of Monte Video, to Ernestine, fourth daughter of Hilarion Vivanco, Esq., of Tigre.

GREENSILL—BRETTELL.—On the 9th inst., at the Parish Church, Dudley, James Heynes Greensill, M.R.C.S., L.S.A., of Parkstone, Dorset, to Ellen Blanche Brettell, eldest daughter of Thomas Brettell, of Dudley.

HALLIBURTON—DAWE.—On the 2nd inst., at All Saints, Gordon-square, W.C., by the Rev. E. G. Hall, W. D. Halliburton, M.D., to Annie, daughter of James Dawe, of Antony, Cornwall. No cards.

JOHNSON—WELCH.—On the 31st ult., at St. George's, Kidderminster, Thomas Johnson, M.R.C.S., L.R.C.P., to Beatrice, youngest daughter of John Welch, of Kidderminster.

JOSHUA—MURRAY.—On the 9th inst., at St. James' Episcopal Church, Dollar, by the Rev. H. K. Maskew, the incumbent, Francis William Joshua, L.R.C.P., L.R.C.S.I., of Great Malvern, son of William Joshua, F.L.S., of Cirencester, to Elizabeth Agnes Murray, of Dallarbeg, Dollar, eldest daughter of the late John Edwards Murray, sometime of Quartertown-park, Mallow and Rock Lodge, Youghal, co. Cork.

KELLIE—DUNLOP.—At Southfield, Dunbar, by the Rev. R. Buchanan, Geo. Jerome Kellie, Surgeon, 4th Regiment of Cavalry, Hyderabad Contingent, to Eliza Catherine, third daughter of the late Dr. Jas. Dunlop, of Abbey Lands, Dunbar.

MORRIS—NUTT.—On the 4th inst., at Emmanuel Church, West Dulwich, Clarke Kelly Morris, M.R.C.S.E., L.S.A., of Blackheath, son of Edwin Morris, M.D., F.R.C.S., of Spalding, to Mabel Josephine, daughter of the late D. Nutt, of 270, Strand, and stepdaughter of the late D. W. Logie, of Rosendale Hall, West Dulwich.

NOAKES—ASHMORE.—On the 8th inst., at All Saints, Margaret-street, by the Rev. A. J. Noakes, brother of the bridegroom, S. S. Ashmore Noakes, L.R.C.P., M.R.C.S., of Nice, and St. Winifred's, Windsor, to Harriette Paley, eldest daughter of the late Major Ashmore, 16th Regiment, of Bath.

TURNER—MCDOUGALL.—On the 7th inst., at St. Mary Abbot's, Kensington, Francis Charlewood Turner, M.D., to Mary Colenso McDougall.

WALKER—BRIDGE.—On the 2nd inst., at the Parish Church of St. John, Clapham-rise, Charles Rotherham Walker, M.D., to Lilla Gertrude Mary, third daughter of the late Alexander Bridge, M.D., F.R.C.S., of Argyll-place, W.

WALLACE—VACHELL.—On the 9th inst., at St. Andrew's Church, Bath, Samuel Wallace, L.R.C.P.Ed., L.R.C.S.Ed., of Cardiff, to Emily Harriett, youngest daughter of the late Dr. Vachell, of Cardiff.

WELLER—SEVERNE.—On the 2nd inst., at Dringhouses, York, Charles Joseph Weller, M.R.C.S., L.R.C.P.Lond., to Ellen Frances Louisa, daughter of Captain Severne, late of Dringhouses.

DEATHS.

BAIN.—On the 31st ult., at Brighton, Alexander Gordon Bain, R.N., Surgeon (retired), aged 49.

GRANGER.—On the 11th inst., at his residence, Alveston Lodge, Durdham Down, Bristol, Frederic Granger, M.R.C.S., L.S.A., in his 89th year.

HOLL.—On the 11th inst., at his residence, Derby-villas, Cheltenham, Harvey Buchanan Holl, M.D., M.R.C.S., aged 65.

JELLY.—On the 14th inst., at Buxton (suddenly), Fred. A. Jelly, M.B., C.M., the beloved son of Wm. Jelly, M.D., F.R.C.P.Lond., late of Valencia, Spain, aged 29.

LEWIS.—On the 13th inst., at Loughton, Essex, William Thomas Lewis, M.R.C.S.Eng., L.S.A., in his 58th year.

MILLER.—On the 31st ult., at Beaumont-villas, Spring-grove, Isleworth, George Miller, M.D., formerly of Emsworth, Hants, and Sidmouth, Devon, in the 76th year of his age.

MOINET.—On the 6th inst., at Edinburgh, Francis Walter Moinet, M.D., F.R.C.P.E.

STEPHEN.—On the 11th inst., at Carlsbad (of cholerine), William H. G. Stephen, M.B., C.M.Edin., L.R.C.P.Lond., youngest son of the late William Stephen, of Inchbroom, Morayshire, aged 24.

THORNTON.—On the 7th inst., at Hinxton Grange, Saffron Walden, Eleanor Philippa, the beloved wife of J. Knowsley Thornton, M.B., C.M., of 22, Portman-street, London, W.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

We cannot undertake to return MSS. not used.

THE HOSPITAL FOR WOMEN AT LIVERPOOL AND THE NEWSPAPERS.

OUR opinion is asked as to the propriety of medical men carrying on controversies on medical matters in the daily papers. As a rule, the practice is one to be deprecated most strongly. In this particular case, however, it must be admitted that there is some excuse for a departure from the rule. The questions involved have been made public; they have been tried in a court of law. The interest of the hospital, too, and its management are involved by the publicity given to statements in the course of the trial. Any attempt to suppress newspaper discussion would be misconstrued, and would operate adversely on the hospital. Undoubtedly, the sooner medical men withdraw from the newspaper discussions of these topics the better, provided the public is assured that sound rules of professional conduct are laid down, and security has been taken for their being well observed. Voluntary hospitals would collapse without such precautions.

W. V., L.R.C.P.E.—Our correspondent cannot now register without obtaining a diploma. The last day for registration on the ground of "being in practice before ... using of the Act" expired on July 31st, 1879. There is one Dr. S... to this rule—viz., if a person was apprenticed to a dent... London; ...loner and paid a premium prior to the passing of the Act he is ... permitted to register as a dentist.

Mr. Robert Hamilton.—Dr. Diver's book, "A Young Doctor's Future," published by Smith, Elder and Co., might be of service.

Rodney should apply to some such firm as Moore and Co., 125, Houndsditch.

"TREATMENT OF STOMATITIS."

To the Editor of THE LANCET.

SIR,—In response to your correspondent, "M.B.," regarding the treatment of stomatitis, I should suggest the following, which I have never found to fail with cases that have come under my notice. First have recourse to mel boracis, to which add a little pot. chlor., and paint the affected parts with a camel-hair pencil three or four times a day. Should the above not suffice, after a fair trial use the sulphurous acid together with the above, which may also be applied with a camel-hair pencil. However, I think the better plan is to use the acid with a spray, because the affected parts are more easily reached in that manner. Be most particular about the diet, and give some mild tonic, to which add pot. chlor. I have every reason to believe that if the above is carried out, the result will be found most satisfactory.

I am, Sir, yours truly,

Aug. 30th, 1886. M.D.

TOUTING FOR PRACTICE IN NORTH LONDON.

M.B.Edin. sends us two bad specimens of touting. One in the form of a visiting card left at the house of a patient of our correspondent, and having on it, "DR. T——, Surgeon and Accoucheur, Willoughby House, Willoughby-road," and said to have been left at the other houses in the road. The other a handbill announcing the opening of a practice at Andover House, Devonshire-road, Holloway, by a registered physician, surgeon, and accoucheur; fees charged strictly moderate for cash, &c. Really, this is too bad. What are our corporations about to allow such practices by their licentiates? Our correspondent should forward the documents he sends us to the bodies from which these parties obtained their diplomas.

M.A. & D.D. will see by our answer to other correspondents that we have resolved not to continue at present the discussion on the recognition of foreign degrees. That some such degrees must be recognised is clear; but whether "useful work among the poor," any more than among the rich, will be done by men with low degrees we very much doubt.

Mr. M. R. Edwards.—We have no knowledge of any such society as that mentioned.

Mr. Bedford Fenwick.—The paper is marked for insertion.

Dr. Arthur H. N. Lewers.—Yes.

"UNQUALIFIED ASSISTANTS."

To the Editor of THE LANCET.

SIR,—I have read with interest a letter in your issue of the 4th inst. in reference to the employment of unqualified persons as assistants and locum tenens. A great deal has been written on the subject, without, I regret to say, so far, making any apparent change in such a decided abuse. That the system of employing unqualified assistants is extensively carried on not alone in the Midland counties, but throughout England, I have had ample and varied opportunities of knowing. I am at present engaged, and have been from time to time for nearly three years in different parts of England, as locum tenens, and have also held two or three assistantships. I am therefore in a position to give some information as regards the abuse complained of. One or two instances of my experience may perhaps be of interest.

Shortly after I qualified I sought an engagement as assistant, and was engaged to take charge of a branch practice in London. At this branch was an unqualified person, who had had the management of the practice for four or five years, with only an occasional visit from the principal. When I entered on my engagement it was arranged that this unqualified man and I were to live together. I was led to expect that he would attend to such duties as dispensing, &c.—duties fitted for an unqualified person. I soon learned, however, that I was only nominally in charge of the practice; that this ignoramus was really the person invested with the management of it, and that I was, so to speak, his assistant. His salary was double that which I received; he was looked upon by the patients and general public as the owner of the practice, and was usually addressed as "Dr. ——." Of course, I was looked down on as nobody, and on one or two occasions he even consulted with a qualified practitioner, this gentleman being under the impression that he was consulting with Dr. ——. Having for a time submitted to this state of things, I gave this unqualified person to understand that I would not submit any longer. This elicited some hot words, with the result that I had an interview with the principal, in which I informed him that either his reliable unqualified deputy or I should leave. The principal having evinced an unwillingness to part with this distinguished representative of unqualified practitioners, I accordingly decided to leave, and left in a few days without the usual month's notice. I know of many other cases in which unqualified assistants are employed, and entrusted with the lives of hundreds of people, the principal only putting in an occasional appearance—once a week, or perhaps [illegible] often. The generality of unqualified assistants have never [illegible] hospital, can scarcely tell the heart from the liver, and [illegible] passed a preliminary examination. On the other hand, [illegible] unqualified assistants (they are, indeed, "few and far between") [illegible] have taken out all their lectures and hospital practice, and are really hard-working students, but are through pecuniary difficulties unable to qualify.

I am, Sir, your obedient servant,

Bath, Sept. 6th, 1886. JAMES J. O'BRYEN, M.D.

MECHANICS AT THE PRELIMINARY EXAMINATION.—A CORRECTION.

IN the answer addressed to "Student" in our issue of the 4th inst., p. 477, the date of the regulation of the General Medical Council respecting the above should have been given as Oct. 1st, *1885*, not 1886.

P. Q. Y.—Certainly so. No qualification is required to enforce a midwifery charge. Even a midwife is worthy of her hire—much more a member of the English College of Surgeons.

Mr. A. De St. Dalmas.—It would be premature to express an opinion of the merits of the invention until some experience has been gained of its utility.

A. P. S.—The question has been repeatedly answered in our columns—e.g., THE LANCET, March 13th, 1875, and July 14th, 1883.

Meg.—Yes, shortly.

A PRESCRIPTION BOOK OF THE ELEVENTH CENTURY.

MEDICINE has her archæology like every other learned vocation, and hardly a year passes without adding to her treasure-trove. In one of the precious MSS. contained in the Capitular archives of Ivrea, in Piedmont, Prof. Piero Giacosa has found a book of receipts which remounts to the eleventh century. The professor discourses learnedly on this book, pointing out, amid the scarcity of medical writings at that remote date, the importance of a document which adds to the proofs—authentic, if rare—that the ancient Græco-Latin tradition of medicine was still preserved, and that it may have given origin, without the intervention of Arabian medicine, to the famous school of Salerno. The MS. in which the book is inserted belonged to Warmund, Bishop of Ivrea, famous even in the first years of the stormy eleventh century for his love of science and literature. Before the prescriptions comes a group of receipts for writing with gold, for making gold ink, and for illuminating parchment. Then follows a catalogue of maladies, thirty-two in number, more than half of them relating to the eyes, while the remainder have reference to the head, the ears, the throat, the kidneys, and so forth. Each malady has its remedy—one or more,—the majority belonging to the vegetable kingdom, though the animal world supplies not a few. Among the latter we have fat of eels, raw flesh, the gall of a great variety of animals, such as the eagle, the cock, the hyæna, the hare; then goat's dung, hartshorn, serpents' skins, worms, &c. The vegetable remedies include aloes, camphor, cassia, lettuce, honey, opium, sundry aromatic herbs, rue, linseed, mustard, and so on. Finally come a few chemical and inorganic remedies: orpiment, lime, nitre, sulphur, French soap, &c. According to Prof. Giacosa the medicines are mostly derived from Dioscorides and Pliny. He also finds a correspondence, in the matter of arrangement, between the prescription book of Ivrea and the work of Lucius Apuleius Platonicus on the virtues of herbs—a work of which the compiler of the prescription book availed himself as a guide, and of which the Chapter of Ivrea doubtless possessed a copy now lost. The original part of the prescription book betrays a scientific turn of mind in advance of the age as to the conception of disease and the *modus operandi* of remedies. The author signs himself "Petrus Magrus"—probably a fictitious name, it having been the frequent habit of early mediæval writers on medicine to assume the surname "magrus" (lean), an epithet, according to Prof. Giacosa, which implies a not very lucrative practice. The importance of the professor's discovery, as we have said, lies in its demonstration that in Italy the Græco-Latin tradition in medicine was never lost. In fact, in the Ivrea MS. there is mention of but one remedy due to the Arabs—to wit, camphor. This drug, isolated among the others, proves that while in the eleventh century the Arabian pharmacopœia was not unknown, it had not yet, as a whole, taken root in Italy.

M.B. Lond.—The subject being newly introduced into the examination its scope is not sufficiently defined to warrant the giving of precise advice as to reading. Carpenter's "Mental Physiology" and Maudsley's "Physiology of the Mind" are works of considerable reputation, and would probably be useful.

E. C.—We do not give medical advice.

CHOREA AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—I am looking anxiously for some comment, by someone better able than myself to judge, upon the treatment of the case of acute chorea in St. Vincent's Hospital, Dublin, reported in your issue of Sept. 4th. A child of ten years of age was given sulphate of zinc for fourteen days, in doses which gradually increased to thirty grains four times daily, together with a nightly draught of ten grains of chloral and thirty grains of bromide of potassium. On the ninth day considerable epistaxis and paralysis of the sphincters of the bladder and anus occurred. The circulation gradually failed through the succeeding days, and death took place on the fifteenth day.

I am, Sir, yours obediently,

September, 1886. A GENERAL PRACTITIONER.

DISPUTE AT TREHERBERT.

WE cannot undertake to give any opinion on such a serious and complicated dispute as this on the strength of an entirely one-sided statement. Our correspondent would do well to seek the judgment of a third party on the spot, before whom all facts could be laid.

Sigma.—It is not usual for a house-surgeon to be allowed beer money. In most cases he is provided with sufficient alcoholic beverages, and where this is not done he has to provide himself with them at his own cost. In one hospital, we believe, there is an allowance of a shilling a day, but this is exceptional. The question suggests too much the idea of bargaining with servants as to their "allowance."

A Constant Reader.—The question is a legal one, and we cannot speak positively; but we think our correspondent has a claim on the guardians or the relieving officer.

THE RECOGNITION OF FOREIGN DEGREES.

M.D., Wales, M.D. New York, &c.—We must believe that the Medical Council will be careful in the degrees which it recognises. Our correspondent "M.D." does not say what university it is that requires seven years' study of medicine. The profession must make due representations to the Medical Council when it enters on the grave duty of recognising foreign degrees. Such letters as that of "Nemo" will be more useful later on, especially if shorter. The discussion on the recognition of American degrees and their value must for the present close.

H. J. W.—We cannot at the moment indicate a book which would quite fulfil the requirements of our correspondent; but Cassell's Domestic Medicine might answer the purpose.

Mr. J. W. Orr should consult Mr. Henry C. Burdett's book on Cottage Hospitals.

"THE MEDICAL REGISTER."

To the Editor of THE LANCET.

SIR,—With reference to the complaint of Dr. Britton *re* the Medical Register, surely it is time the profession refused to submit longer to the scandalous manner in which names are removed from the Register. Being about to travel, I sent a notification of the fact to the registrar, enclosing a stamped envelope for acknowledgment (as I was aware that the funds of the Medical Council did not admit of the expense incurred in acknowledging a communication from a registered practitioner). I received an acknowledgment, saying my (then) present address would be retained on the Register. I happened by chance to be in England when the circular referred to by Dr. Britton reached me, and I was able to reply to it. Now, Sir, if I had left England one week earlier, I conclude my name would have been removed from the Register, as, owing to my somewhat erratic movements, it would have been quite a chance whether the communication from the registrar had ever reached me, and I should have been absent from England probably twelve months. A qualified practitioner pays an exorbitant fee for the privilege of being registered, and receives the following benefits:—He helps to pay the Medical Council enormous fees for the time they waste in framing new rules and regulations for the profession at one meeting which they usually annul at the next. The names of registered practitioners are removed from the Register whenever, in accordance with the most arbitrary and ridiculous rule of the Council, the registrar can do so, whilst no steps whatever are taken to expose and stop the practice of numerous unregistered and unqualified persons who style themselves doctors, who impose on the public and bring great discredit on the profession. I am, Sir, your obedient servant,

Sept. 7th, 1886. REGISTERED.

Mr. H. Bedwell.—There is no evidence that we are aware of in favour of the belief.

IRON IN ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—On May 16th, 1884, you inserted a letter in your columns which referred to the value of iron in septicæmia. In the closing sentence of that communication I mentioned the use of that drug in the treatment of enteric fever. I have recently used the perchloride in five-drop doses in two cases of that disease, and have been much pleased with the result. The temperature fell to the normal in from eight to twelve days. The iron, sweetened with glycerine, was given every two hours. The diet was strictly a milk one. I am, Sir, yours truly,

Clayton-le-Moors, Aug. 26th, 1886. C. R. ILLINGWORTH, M.D.

M.B.—Has our correspondent considered that there are already two London candidates well to the front?

Mr. J. H. Bell.—THE LANCET, Nov. 3rd, 1883.

"THE USE OF COCAINE IN CIRCUMCISION."

To the Editor of THE LANCET.

SIR,—Dr. Hett's last letter reduces the controversy between us practically to two issues:—1. If there be no phimosis, is a redundant prepuce in the slightest degree prejudicial, either to the child or to the adult? 2. Is the compulsory cleanliness procured by its excision any sufficient warranty for the performance of circumcision? My own impressions lead me to answer both questions in the negative. Dr. Hett, of course, takes an opposite view; it is for others to judge which is right. It is sufficient for me to have pointed out that congenital phimosis can be easily remedied by a much simpler and safer procedure than the one now almost universally in vogue.—I am, Sir, yours faithfully,

Norfolk-terrace, W., Sept. 7th, 1886. HERBERT SNOW.

THE CONTAGIOUS DISEASES ACTS.

To the Editor of THE LANCET.

SIR,—May I be allowed to draw attention to the following words, spoken last week in the House of Commons by Lord C. Beresford:—"The large increase in the sick-list in the Navy was due to the abrogation of the Contagious Diseases Acts and to the campaign recently undertaken." It is quite refreshing to read such words coming from a man like Lord C. Beresford, and protesting as they do against the short-sighted legislation which removed the protection of these Acts from our garrison towns and seaports.—I am, Sir, your obedient servant,

Charlotte-street, W., Sept. 13th, 1886. H. DE MÉRIC.

"SEPARATE" QUALIFICATIONS.

THE following circular, obviously for wide distribution, sets the subject of separate qualifications in a new light:—

"122, Southwark Park-road, S.E., August, 1886.

"Dr. Rugg presents his compliments to the inhabitants of this neighbourhood, and begs to inform them that he has commenced practice at the above address. Dr. Rugg holds *separate* diplomas in every branch of his profession—i.e., as a physician, surgeon, apothecary, and accoucheur. He has had a large experience of surgical cases, gained during the Franco-Prussian War, and later as medical officer in the Australian mercantile marine. He therefore hopes that by careful and conscientious attention to the duties of his profession, and by combining his mature experience with the most moderate charges, he may be enabled to gain the confidence and patronage of his neighbours. Dr. Rugg would further state that having received an extra degree in diseases peculiar to women and children, offers them special attention."

Then follows a tariff.

Enquirer.—Our advertising columns contain all the information we have upon the subject.

Dr. H. Snow's paper will appear shortly.

"A NEW AND IMPROVED CLAMP FOR HÆMORRHOIDS."

To the Editor of THE LANCET.

SIR,—Returning from a happy little holiday, I regret to find I have given pain to Mr. Benham; He should bear in mind that when we offer anything to the profession, as both he and I have done with our clamps, we must be prepared to accept criticism, even though it be adverse. In my own practice I have had every reason to be satisfied with the instrument which I devised for myself in preference to his, and even Mr. Allingham's. Practically my instrument proves perfectly efficient and reliable. Mr. Benham's experiment at the maker's was made with an imperfect and rejected clamp—rejected for the reason that it permitted play between the collar and shaft. A perfect instrument was shown by me when I read a paper at the recent meeting of the British Medical Association here, and it met with a reception quite satisfactory to

Yours faithfully,

Brighton, September, 1886. CHARLES J. SMITH.

Scalpel.—Our last week's issue contains the information required.

Mr C. H. Eyles.—Soon.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Simeon Snell, Sheffield; Sir James Sawyer, Birmingham; Sir William Smart; Mr. W. J. Baker, Kashmir; Mr. Leeming, Kendal; Dr. F. E. Pearse, Frome; Mr. A. de St. Dalmas; Dr. Whitla, Belfast; Mr. Holderness, Windsor; Mr. De Méric, London; Mr. Foulerton; Dr. Hingston Fox, London; Mr. W. Fraser, Ashburton; Mr. R. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Introductory Address

DELIVERED AT

ST. THOMAS'S HOSPITAL,

At the Opening of the Winter Session 1886-87,

BY J. S. BRISTOWE, M.D., LL.D., F.R.S.,

SENIOR PHYSICIAN TO THE HOSPITAL.

MR. TREASURER AND GENTLEMEN,—At the request of my colleagues I appear before you to-day to give the introductory address. I need scarcely say that I deeply appreciate the honour which they have done me, and the privilege it confers upon me of delivering myself as I please on whatever subject I may choose as suitable for the occasion; yet I must confess I would gladly have declined the honour and foregone the privilege had I dared. For, as we are constantly reminded by our critics, we orators of the 1st of October rarely say anything particularly new or particularly worth hearing; and it requires some exercise of moral courage for one who acknowledges that he has nothing new or important to say, and who finds himself for the third time in this unhappy position, to brave the adverse criticism which he feels that he shall deserve, and which has been passed upon him over and over again by anticipation. On the other hand, gentlemen, for reasons which I will briefly state, I have always been a consistent advocate of the maintenance of the custom which we are met this day to honour. It is admitted that the duties of the lectureship are difficult of adequate fulfilment; but if difficult, so much the more is success worth achieving, and at any rate the mere endeavour to do one's best is a wholesome experience (I am saying this for the benefit of my younger colleagues). The occasion is one which, as I believe, most old pupils regard with interest; and certainly it never fails to attract, besides new faces, many old friends whom it is a pleasure to greet. The introductory speechifying, moreover, however poor many of the addresses may be or may be thought to be, is made the occasion by the daily papers of drawing the attention of the public to the large hospitals and to the important educational work which is being systematically carried on in them and in the medical schools associated with them. Lastly, the oratorical display of October 1st is a time-honoured institution which links the present with the past, and on which respect for our predecessors and veneration for what is old should restrain us from laying violent hands. I felt it, therefore, my duty to accept—and I accepted readily, but not without misgiving—my present responsibility.

I have alluded to the fact that this is the third occasion on which it has fallen to me to give the introductory address. The first was eight-and-twenty years ago, and my lecture was delivered in the grand old hall of the hospital in the Borough before an audience of ladies and gentlemen (for ladies at that time were invited to be present), and prior to the distribution of prizes, which then also took place on the 1st of October. I was a young man then, and felt it a high honour to be invited by my older colleagues to represent them on the occasion; and, like a young man, I did represent them in a speech of such eloquence and floweriness that now in a calmer and more critical period of life I can scarcely understand how it was I had the presumption to deliver it or even to write it; and so full of admirable advice, that it might have been in this respect the joint production of the Archbishop of Canterbury and my friend Mr. Mac Kellar. Nevertheless, it was kindly received, and if any felt the amusement in hearing it which I felt in recently perusing it, they did not show it.

My second lecture was given four years later. In the interval vast changes had occurred. The old Borough Hospital had been sold to a Railway Company, the institution had just found a temporary home in the Surrey Zoological Gardens, and what the future was to be was a problem awaiting solution. Crude sanitary notions were at that time rampant; sanitary reformers inveighed against the iniquity of retaining establishments for the treatment of the sick in towns, and the enforced removal of St. Thomas's was hailed by them as a glorious opportunity for translating their theories into fact at the expense of one of the largest and richest metropolitan hospitals. Unfortunately, too, the treasurer for the time being, and some of the more influential governors, were largely under the influence of the prevailing sanitary craze, and also were inclined to transport the hospital wholly or in part into the country. The plan which most commended itself to them was to erect and maintain a small receiving house or hospital for acute and urgent cases in London, and to build a large hospital some miles away in the country, to which convalescent and chronic cases, and, in fact, all patients who were not likely to be injured by the journey, should be conveyed. The views of the governors had not been submitted to the medical officers for consideration, nor had their collective opinion been sought in any way; nor, again, had the medical officers (not accurately knowing what was gong on) held any meeting to discuss and consider the state of affairs. I need scarcely say that the position was a very difficult and critical one, and the prospect exceedingly gloomy. The hospital and school, both of which had been in abeyance for a few months, opened simultaneously on Oct. 1st. The inaugural ceremony, including the distribution of prizes, attended as before by ladies, took place in a large tent erected for the occasion. My address, I admit, presented occasional outbreaks of grandiloquence quite worthy of my former self, but I am pleased to say that on the whole my style had become much more sober than it was in my earlier essay; nor did I again venture after so short an interval to inflict a sermon on my younger auditors. The occasion, in fact, was unique, and I gladly availed myself of the opportunity it afforded me to discuss the future of the hospital and school, arguing as strongly as I could in favour of retaining them wholly in London, and refuting as vigorously as I dared the views (so far as I understood them) of the treasurer and his supporters. I cannot pretend that my lecture had any direct influence; but it was, I believe, the first distinct public expression of opinion adverse to the views of the sanitary crotchet-mongers, who, if they had had their way, would have ruined our school and converted our great hospital into a mere sanatorium. Subsequently, other men of greater influence and greater ability than myself took up the matter energetically from the same point of view as I had done, and before long common sense was triumphant, and the danger which had seemed imminent was averted. Few persons now know how much we are indebted to Mr. Simon and the late Mr. Whitfield for the acquisition of the magnificent site on which the hospital now stands.

My third appearance occurs under very different circumstances from those which attended my first two lectures. I was then young; I am now, I prefer not to say old, but at any rate no longer young. I was then at the bottom of the hospital staff; I am now at its summit. I then lectured to students whose younger sons are probably listening to me for the first time to-day; the troublous times have passed, and we are now, and have been for some years, in the sunshine of assured prosperity.

What should be the subject of my discourse on the present occasion? I have already uttered more good advice than I ever knew how to follow, and I do not care to furbish up my old lecture. I scolded the authorities at an important crisis in the history of the hospital, but there is no crisis now and no occasion of quarrel. Even if there were I would avoid it. You may perhaps agree with me, gentlemen, in thinking that the fact that the dates of my three addresses correspond to three important periods in the history of our hospital and school suggests, as the obvious answer to my query, that my present address should be mainly retrospective.

The first seventeen years of my professional life, during which I was successively student, teacher, and physician, were passed in connexion with the hospital in the Borough—the hospital of Meade, Fordyce, Elliotson, and Robert Williams; the hospital of Cheselden, the two Cline, Travers, and Green. It is not unnatural, therefore, that I should still feel affection and veneration for that ancient and ennobled building, and should look back wistfully to the many happy and instructive hours spent within its walls. At the time at which I became a student, the school of St. Thomas's had just emerged from that cloud of failure and disaster (the causes of which I need not enter upon) under which it had lain for many years, and though the entries were still few,

the school on the whole was extremely well managed, and the teachers as a rule were exceptionally good. The hospital, of which an excellent model is preserved in our central hall, was one of the largest and best appointed in the United Kingdom. The greater part of it dated from the early years of the last century, and bore a close resemblance to the older part of Guy's. The old wards were not perhaps exactly the kind of wards that one would erect nowadays; but they were roomy, well-ventilated, and healthy, and answered their purpose. Two new wings, abutting on the High-street, had been recently erected, and it was intended that all the ancient part of the hospital should (as funds allowed) be taken down, and replaced by blocks on the same plan. The new wings were handsome structures, and the wards the noblest I have ever seen. Had the reconstruction been completed, St. Thomas's in the Borough would have been, I think, even a grander hospital than its grand successor, though possibly its arrangements might not have so well fulfilled all the sanitary requirements of this fastidious age. The school buildings were compact and well arranged, with a magnificent lecture-theatre, and an excellent museum, library, dissecting-room, and chemical laboratory.

Among the physicians, surgeons, and other teachers were many men of high eminence. Robert Williams, the author of the classical work on "Morbid Poisons," and one of the most philosophical physicians of this or any age, was the senior physician in my first year, and died in the course of it. I only have a vague recollection of seeing him occasionally cross one or other of the hospital squares. Next to him was Dr. Burton, whose name is identified with the discovery of the blue line on the gums in connexion with plumbism. He was, as far as my memory serves me, a quiet, amiable, gentlemanly man, and much liked; but he died of cholera in the epidemic of 1849, and I never, therefore, became very well acquainted with him. Dr. Barker and Dr. (now Sir) Risdon Bennett were also members of the staff, and before long were joined by the late Dr. Peacock. It was to these three able physicians mainly that the students of the period to which I am now referring owed their training in clinical medicine. Many an old student will recall the Dr. Barker of those days, twirling a quill pen windmill-like between his finger and thumb as he walked from ward to ward. I think most of us were a little bit afraid of him; but we all acknowledged his great qualities as a physician, his intimate acquaintance with morbid anatomy, his remarkable accuracy of diagnosis, and his simplicity and directness of treatment. Very few of those who wished to learn medicine failed at one time or another to attend his clinique. Dr. Bennett, again, is not likely to be forgotten by those who studied with him at that time. He, too, was recognised as an admirable physician, and as one who gave special care to the therapeutical and dietetic treatment of disease. There was never a more painstaking, accurate, and methodical physician than Dr. Peacock. He took the notes of all his cases in great detail, and generally dictated them to his clerks. His teaching, therefore, though excellent in quality, was perhaps a trifle dry and unattractive; nevertheless, it was very highly appreciated. Among the surgeons Joseph Henry Green took the lead. He enjoyed an immense reputation, and I believe deserved it. He was of lofty stature and commanding presence, with a handsome intellectual face. He was a man of rare endowment and wide culture, and an admirable surgeon. He was a consummate orator. I did not know him at his best; for though he did his work in the hospital and school, he had ceased to take much interest in it. His lectures were the lectures which he had delivered without change for years. In the hospital visits he was always accompanied by his assistant, Mr. Solly, who did most of the duties under the eye, and liable to the correction, of his superior. John Flint South was a man of a very different stamp. He was kind-hearted, but hot-tempered and crotchety, and delighted to put on a roughness and not unfrequently a coarseness of manner which those who knew him could pardon on account of his many excellent qualities, but which to strangers and patients was often offensive. But he was a most industrious man, and performed all his duties with remarkable thoroughness and conscientiousness. I suppose people now rarely consult his great edition of Chelius's Surgery, of which his own notes formed by far the larger portion, and I am inclined to think by far the more valuable. It would be impossible in the limits of a brief address to speak of all the members of the staff. But I must not overlook Samuel Solly, Le Gros Clark and John Simon. Solly was a brilliant and enterprising surgeon. But he was more than that, for he wrote a work upon the anatomy of the brain which had and deserved a high reputation; and he was a landscape painter of no mean skill. Of Le Gros Clark and John Simon I should like to say much more than I dare. Suffice it for the moment that to these two great surgeons and to South and Solly, probably more than to any others, students were indebted for their surgical education.

Although there was abundant opportunity of learning medicine and surgery in the wards and in the out-patient rooms, students were not required, as they are at the present time, to take clinical appointments, and most of the more valuable posts that are open to them now did not then exist. The clinical clerkships were got for asking, and those who did not ask were not appointed. There was no such post as that of house-physician, but all medical duties in the absence of the physicians and surgeons were performed by the apothecary and his assistant. The dresserships were more sought for, and indeed they were of remarkable value, for the dressers enjoyed much more freedom in dealing with patients and in taking responsibility in the emergencies of practice than they are allowed at the present time. But house-surgeoncies were instituted in my own early days (I was one of the first to fill the post), and curtailment of the privileges of dressers began to take place.

We were provided with good teachers. Members of the staff were responsible for the systematic lectures on surgery and medicine, but, in addition, Dr. Marshall Hall lectured on nervous diseases, and Dr. Gregory discoursed on the exanthemata. But it was, I think, in the anatomical and physiological departments that the teaching was most systematic and best. We had no practical physiology in those days, but the systematic course of lectures was efficiently carried out. Richard Grainger had been associated with his elder brother for some years in teaching anatomy and physiology in the Webb-street School, and had been imported into St. Thomas's three years before I joined it. He was an excellent physiologist, one of the best of his day, and his lectures were singularly instructive, clear, and attractive. He was a striking illustration of the fact that a man who is in earnest may be a first-rate lecturer, in the sense of being able to make his meaning clear and to command the attention of his audience, without being in any sense an orator or even a fluent and consecutive speaker. Mr. Grainger was a tall, gentlemanly, quiet, amiable, and amiable-looking man, who took a great interest in his work, as well as in his pupils, who, in return, held him in the greatest affection. I may perhaps recall the fact that latterly much of his time was given to sanitary investigations, and that he was one of the pioneers in the field of public health. Mr. Le Gros Clark was the lecturer in anatomy; and those who know how he speaks now may judge how well and pleasantly he lectured then. Perhaps in relation to this I may venture to recall a little incident of my student days. I recollect that when I went into the anatomical theatre to hear my first lecture I had no notion until the lecturer entered the room what kind of man he was, and I have to acknowledge that I was so far attracted by the personality of the lecturer that, though I was a fairly industrious student, I proceeded to spend my time in taking his portrait in my note-book, instead of paying due attention to his discourse.

I shall not recall all the excellent men who at one time or another taught in the dissecting-room. But in my second year a gentleman became chief demonstrator who, I believe, had previously for a short time occupied the same post, and who continued chief demonstrator for more than thirty years. I speak of George Rainey, who was in the fulness of his powers, I think, during the period to which I am now specially referring. There were men at the hospital of higher intellect, of wider culture, of more imposing presence, and of greater refinement than he; but there was not one whose lessons were more highly appreciated, who had greater influence among the students, or who stands out more prominently among the memories of those days. He was a small, spare, ill-dressed, untidy man, with a bald head, auburn hair, a ruddy face, which in form, features, and expression bore a close resemblance to that of John Stewart Mill, and a weak, husky voice. He passed his time almost wholly between the dissecting-room and a small apartment with a bay window looking into the dissecting-room from above, where the chief part of his microscopical work was done. It was in this room that most of those fine injections for the microscope with which his name

is identified, and of which our museum contains a choice collection, were made; and it was here that he carried out most of those inquiries which brought him reputation as a physiologist and a thinker. Possibly some here present may call to mind one occasion when in the midst of a winter session he obtained leave of absence for six weeks. It was naturally thought he was out of health and wanted change of air. But he passed the whole of the time (excepting the nights) in his den above the dissecting-room, where he could be seen from below deeply engaged in some physiological investigations. His demonstrations were very clear and simple, and largely done by putting questions to those whom he was teaching. But the most interesting feature about the man, and that which chiefly explains the great influence he had over his pupils, was his habit, usually about luncheon time, and later in the afternoon when the daily work was drawing to a close, of sitting in front of the dissecting-room fire and entering into conversation with such pupils as happened to congregate around him. The conversations were on all kinds of topics. But, no matter how they began, they generally before long diverged into discussions concerning science, morality, or religion. A favourite method with him was to fix upon one man, to ply him with questions on the Socratic principle, and then (as often happened), having led him into contradictions, or having made him display his utter ignorance of the subject he was talking about, or having induced him to express views or sentiments which were absurd or reprehensible, to lay bare the unhappy victim's errors and inconsistencies, to overwhelm him with a torrent of chaff, sarcasm, and logic, and to wind up by expressing his own views with a manner and in language which were singularly impressive. Many a student retired from such encounters a good deal crestfallen, but few, if any, showed resentment, and many I am sure were benefited by them.

The celebrated Dr. Thomas Hodgkin had been imported from Guy's Hospital to be the demonstrator of morbid anatomy at St. Thomas's, but he remained only a short time, and had left before I entered. The growing importance of pathology, however, was fully recognised, and it was as a pathologist with clinical duties that Mr. Simon shortly afterwards was introduced into St. Thomas's Hospital. I recollect well the introductory address he delivered in the Grand Hall of the Hospital before the governors, the staff, and the students, on the occasion of his appointment, and its striking eloquence. It is needless to say that whatever Mr. Simon undertook to do, he did with all his strength, and admirably. His lectures on general pathology were always eagerly attended, and were valuable not only for what they taught directly, but for their suggestiveness, and for the impulse they gave to pathological work in the hospital. Among others who lectured at one time or another during this period were some men of assured eminence, and some who were then comparatively unknown, but have since achieved greatness. Among the former were Mr. Thomas Taylor and Dr. Dundas Thomson, distinguished chemists; among the latter, Dr. Gladstone (now a well-known member of the School Board, and a chemist of the first rank as an investigator and discoverer) and Mr. Huxley.

Any picture of the old St. Thomas's would be incomplete which did not include a sketch of the apothecary and medical secretary. There was no more striking figure in the institution than Mr. Whitfield, the third and last of his name who had filled these important posts. He was then a handsome man in the prime of life, and occupied a position which gave him immense influence. He was the apothecary, and that meant, not only that he was at the head of the drug and dispensing department, but that he was the resident medical officer, and exercised control over patients, over house-surgeons and dressers, and over nearly everybody and everything else, and that he shared with the physicians the medical fees. He was the medical secretary, and in that capacity had more authority than anyone else over the medical school and all its arrangements. He was the depository of all the unwritten rules and traditions of the hospital and school. Moreover, he was in fact, though not in name, the treasurer's prime minister. He was thus the most powerful subject in the hospital kingdom. Nor was he the man to let any advantage or influence which he possessed slip from his grasp. As a rule, he no doubt exercised his legitimate and his usurped powers for the benefit of the place, at any rate for what he thought its benefit, and took an active part in introducing useful reforms. But there is also no doubt that he was instrumental in introducing changes of which the staff did not approve, and which many of us thought and think were detrimental in their effects. He was a man of much liberality and kindness of heart, and ever a real friend to the student and all who were in need.

In some important respects the times to which I am referring were times of transition; and not only were great changes actually in progress, but the foundations were being laid of improvements which have since been effected. In my early days the nursing at St. Thomas's, like that at all other hospitals, was, to say the least, discreditable. The sisters were, for the most part, respectable women, if not trained nurses, and some were women of remarkable ability and fitness. But the nurses generally were slovenly, dirty, and disreputable, which is not to be wondered at when it is borne in mind that they not only nursed the patients, but scrubbed the floors, purchased and cooked their own food, and slept, many of them, outside the hospital. But after a few years the treasurer of that time, the late Mr. Baggallay, with the aid mainly of Mr. Whitfield and our present excellent matron, cleansed the Augean stable, and gradually introduced the system of nursing, which has become perfected with time and now prevails. The reconstruction of the nursing department led, in the course of a few years, to further far-reaching arrangements. For when, shortly after the Crimean war, Miss Nightingale had decided that the national testimonial which had been presented to her should be devoted to the establishment and maintenance of a school of nurses, she, on account of the recognised excellence of our nursing arrangements, entered into negotiations with the governors, which resulted in the establishment of the Nightingale School in connexion with St. Thomas's—a school which for more than a quarter of a century has provided skilled nurses for hospitals and infirmaries throughout the British dominions, has helped to develop and still further improve our own nursing, has been the parent of many similar institutions, and still flourishes in our midst. As I have already stated, the house-surgeoncy was instituted within my recollection. The creation of this office foretold the creation of the correlative office of house-physician. But, though the importance of such an appointment was fully recognised, it was not possible to make it until the retirement of Mr. Whitfield should leave the authorities free to deal with the clinical portion of his duties; and that was not to take place for a good many years. And lastly, the medical and surgical registrarships, appointments valuable for the hospital and valuable for those who hold them, were created towards the end of this time. It may be interesting to recall the fact that the first registrar was my colleague Dr. Ord; the second, my colleague Dr. Stone.

It will be acknowledged, I think, gentlemen, that St. Thomas's in the Borough during the time I knew it was a great and growing institution, and that the survivors of those who were then connected with it, and their heirs, are justified in looking back upon it with pride. The hospital itself was a grand hospital. As I have shown, among the physicians and surgeons were men of the greatest eminence in their profession; among the lecturers and teachers men whose teachings were unsurpassed. I am bound also to acknowledge that, though we were not always on such good terms as were desirable with the treasurer and the governors who acted with him, these gentlemen had the good of the hospital and school at heart, and did much in many ways, and much successfully, to promote their interests and advancement. The school, too, was successful. Students had excellent opportunities afforded them, and, on the whole, were well taught; and many men who have since achieved eminence were turned out by us in those days. Our numbers, too, had been gradually increasing, so that latterly we were treading on the heels of our successful rival, Guy's. When I delivered my first address in 1858 there was no suspicion of the fate that was impending; everything was prosperous, and prosperity seemed assured. A few domestic troubles occurred, indeed, about this time; but they were temporary troubles affecting the staff and teachers, and not the students, and could have had little, if any, injurious effect on the progress of the school. In 1862 the hospital became the property of a railway company, and for some months hospital and school were in abeyance.

When the crisis came it was a subject of serious consideration among those who were in authority whether the hospital should remain dormant until a new permanent hospital was erected on a new site, or whether in the meanwhile it should go into lodgings. By the adoption of the former plan much money would have been saved, which

would have gone towards defraying the cost of the new buildings; by the adoption of the latter the continuity of the beneficial functions of the hospital would be secured. I think the governors did right to adopt the latter alternative. But it was also a serious question among the members of the medical and surgical staff and the lecturers whether, even if the hospital should continue its functions, the medical school should be maintained. For some thought that the maintenance of a failing school would be attended with no credit or advantage; and everyone knew that, as in order to keep the school together the expenditure would have to go on as before, there was not only a strong probability that the surplus for division would prove scarcely worth dividing, but a possibility that the lecturers and teachers might have to put their hands into their pockets to pay for the privilege of teaching. It was decided to continue the school; and, again, I think the right course was taken. I may mention, however, that the latter anticipations were in the main justified; for on looking through my memoranda for the purposes of this address, I find that for seven years of those passed in our temporary abode my average yearly income from the school was just £16 10s., and in one year amounted to the magnificent total of £12. I was lecturing on physiology with Dr. Ord.

The site acquired for the temporary hospital and school was the old Surrey Zoological gardens, which had ceased for some few years to fulfil their original functions, and in which there had subsequently been erected a large hall for music and dancing, where also Thackeray lectured and Spurgeon preached. With no little skill the building was converted into a hospital of three floors, of which the lowest one was devoted, half to the purposes of a ward, half to the out-patient department, and of which each of the upper two floors constituted one magnificent ward holding upwards of eighty patients. The hospital contained about half the number of beds the old hospital had contained. It was designed only for temporary occupation, and its plans and arrangements had of course to be made conformably to the capabilities of the building to be adapted. Nevertheless, the arrangements were really good; the wards were very imposing, light, airy, and convenient, and they remained sweet and healthy to the last. The infectious cases were accommodated in the giraffe-house. The museum, library, dissecting room, and lecture theatres were distributed about the grounds, some occupying the monkey-house and other former abodes of beasts or birds. The school buildings, though they had been hastily prepared and were somewhat rough in character, were fairly convenient, and no one had much reason to complain of them. But the charm of the place was the beautiful and large garden in the midst of which the hospital and school were placed, with its pretty walks, its avenues and copses, its flower beds and lawns, and its picturesque lake of one or two acres or more in extent.

By this time many changes had taken place in our staff of medical officers and lecturers, and many others occurred before we found ourselves in the building in which we are now assembled. Green and South had retired from the surgical staff, and Grainger from the physiological lectureship, and, among others, Dr. Brinton had been added to our number. Before we left the Surrey Gardens Barker and Bennett, Solly and Le Gros Clark, had all taken farewell of us, and Brinton had died. I may add that few of the later vacancies thus created were immediately filled up; not, however, because suitable applicants were not forthcoming, but partly because a large staff was not needed for the work of the hospital, and partly because it was thought best that the inauguration of the new hospital that was preparing for us should be made the occasion for strengthening the staff by the addition to it of a careful selection of men of eminence or of promise, whether educated in our school or attracted from other institutions.

There are two men whose names are identified with the later history of the old hospital and the earlier history of the temporary hospital of whom I may venture to speak. Dr. Brinton became connected with the school, as Mr. Grainger's coadjutor in the chair of physiology, at a time when Mr. Grainger was beginning to find his strength failing and unequal to the work required of him. He was a man of much ability and brilliancy, an eloquent and effective lecturer, and, as a physiological lecturer should be, an excellent draughtsman. After a few years he was appointed one of the physicians, and at once took a leading position as teacher. His career unfortunately was a short one, and he died while quite young of kidney disease. The other was a man whom I have not yet named, and who, I daresay, has long slipped out of the memory of many here who were once familiar with him. I speak of Edmund Montgomery, who for several years was our demonstrator of morbid anatomy. I think, however, some may manage to recall that tall, slim, handsome young man, with his profusion of crisp, curly, dark hair; with his British name but German accent, for he had been brought up from infancy in Germany among Germans, and when he came to England a few years before he joined us knew little or nothing of the English language. Some of us who were intimate with him knew that he possessed a depth and striking originality of thought, an extent of knowledge, and a command of language which casual acquaintance would probably never have suspected of him. It must be more than twenty years since he left us, and nearly as many since circumstances took him to the wilds of Texas, where he has since resided, leading (not from choice) the precarious and hard existence of a backwoodsman. It will surprise most, and I hope gratify many, of those who were his friends to learn that among his rough, uncouth, and uncongenial surroundings, in spite of continuous daily toil and penury, he has continued to pursue his philosophical studies, and that his papers published during the last few years, discussing with exquisite eloquence profound metaphysical problems, have secured for him at length a foremost place amongst American, and I believe European, philosophers.

Although our migration to the Surrey Gardens, and our sojourn there, were in many ways of serious injury to most of us, although our labours there were carried on under many discouragements and with much inconvenience, although for the second time within the memory of some among us the school had become unprosperous, and although we looked forward to the better days which we saw approaching, I must acknowledge that I look back to our nine years' sojourn in the Surrey Gardens with much more pleasure than pain. There was much good fellowship between all those who were banded together to carry on the work of the institution. The few pupils we had were of more than average merit; they were, I think, content, and certainly were loyal. And there are few more pleasing recollections than those of the academic shades haunted by the studious and meditative, of the grassy lawns alive with cricketers and others who indulged in athletic exercises, and of the frozen lake gay with its crowds of skaters.

The scene once more changes. In 1871 Her Majesty opened the magnificent hospital within the walls of which we are now assembled—a hospital, as far as I know, unsurpassed, and which, whatever its faults may be, and despite all the adverse criticisms of native faultfinders, is the admiration of almost every foreigner that visits it. We turned our backs on the old Surrey Gardens, over which the tide of time has since swept, carrying away with it everything of interest and beauty that adorned its surface, and leaving only a sediment of bricks and mortar; and we entered on our new career with the commencement of the winter session. The hospital, which was now practically completed, had been three years building. During this time arrangements (in which the medical officers had had no unimportant share) were carefully made for strengthening, by the infusion of new blood, the staff, which had been undergoing attenuation through the successive retirement of some of its most experienced and ablest members, and for effecting many improvements in the hospital and school. Among those who were invited to become members of the staff were, on the surgical side, Mr. (now Sir William) Mac Cormac (who indeed joined us ere we left the Surrey Gardens), recommended to us by his brilliant services during the Franco-Prussian war, and by his recently-published "Notes and Recollections of an Ambulance Surgeon"; Mr. Francis Mason, one of Sir William Fergusson's favourite pupils; and Mr. Henry Arnott, who has since left us for the Church, but whom we selected on account of his scientific promise;—on the medical side, Dr. Murchison, whose reputation was even then world-wide; Dr. John Harley, who had passed a distinguished career at King's College; and Dr. Payne, who had already made a reputation for himself as a pathologist; and, lastly, in the ophthalmic department, Richard Liebreich, at once oculist, artist, and musician. It will probably still be allowed, as I think was acknowledged at the time, that the selection was, on the whole, well made, and that the addition of these to a still larger

number of able and distinguished men, already fellow-workers for years, constituted a strong and many-sided staff. Among the beneficial reforms introduced into the hospital were those relating to the resident medical appointments. The long-delayed retirement of the apothecary, who, however, retained his medical secretaryship, made it possible to put the drug and dispensary departments under the care of an educated pharmaceutical chemist, and to bring the arrangements for the care of the medical patients, during the absence of the physicians, into harmony with the corresponding surgical arrangements. I will not discuss details; but all who know anything about the hospital, are aware that the plan of having a resident assistant-physician and a resident assistant-surgeon, who enjoy supreme control in the absence of their superiors over the medical and surgical patients respectively, house-physicians and house-surgeons, who are responsible under these rules for the specific care of groups of patients, and clinical clerks and dressers at the bottom of the scale, who perform various subordinate but necessary duties in respect of the patients and make records of their cases, has answered admirably in practice; that the scientific interests of the medical officers, the educational interests of the pupils, and the sanatory interests of the patients alike have been more and more advanced; and that, while no doubt the nursing of the hospital has been undergoing gradual improvement under the direct and indirect influence of the Nightingale School, the relations between the nursing department on the one hand, and the medical students and others who work in the wards on the other, has become more and more friendly and pleasant. Indeed, the experience at St. Thomas's has shown in the most striking manner that a large medical school and a large nursing school may be carried on concurrently in the same institution, not only without jealously and without quarrels, but with the maintenance of the most cordial relations and to their mutual benefit. Among the clinical improvements, it must not be overlooked that the obstetrical has advanced like other departments, and that the specialties, more particularly perhaps those relating to the eye and throat, have been developed with singular success.

As regards the school, old lectureships and demonstratorships were rearranged, and new lectureships and demonstratorships were created; a redistribution of appointments was effected, and the newly added members of the staff had freely allotted to them such posts as seemed best suited to their abilities and their lines of work. It would be impossible within the limits of time at my disposal to discuss all the changes that were made. Moreover, many further changes have occurred between that time and the present. I may, however, refer to two or three matters. A few years ago practical physiology as a course for medical students was undreamed of; but a department of practical physiology was provided for in the new school, and has been, and is being, conducted with much success. It is only within the last few years that the pathological importance of microbes has been discovered and bacteriology has come to be recognised as an important part of medical study. Thanks to the energy and scientific spirit of Mr. Ballance and Dr. Theodore Acland, a bacteriological laboratory has been established, and is in work. It is well known that the museum of St. Thomas's Hospital has always been peculiarly rich in pathological specimens, and that it contains a series of preparations which are of great historical interest, notably Sir Astley Cooper's collection, including many of those from which the illustrations for his works were taken. The museum was much damaged by its two removals and during its sojourn in the Surrey Gardens; but since it has again found a suitable home, its importance and value have increased year by year, and now, in its way, I should think it is almost unrivalled. We are indebted for the progress, largely to the enlightened liberality of the treasurer and governors, but directly to the admirable labours of two successive curators: Professor Charles Stewart, who was with us for many years, and who was a year or two ago, much to our loss, elevated to the curatorship of the museum of the College of Surgeons; and Samuel Shattock, who now occupies the post, and has signalised his brief tenure of office by the most splendid work, and of whom I may mention especially that during the last few months, with the aid of Dr. Stone and Mr. Plowman, he has rearranged, renovated, and enlarged the Museum of Materia Medica, which, now that it is completed, is probably the finest, most perfect, and most serviceable museum of the kind in existence.

Year by year, gentlemen, during the fifteen years we have occupied our present site, our school, which had been so often and so seriously checked in its career, has increased in usefulness and prosperity, until once more it occupies a leading position among the metropolitan schools of medicine. Nor can I see any cloud in the horizon—any reason why our success should not be maintained in the future. But while the school grows and prospers those who contribute to its progress drop out one by one, and one by one new comers fill the places thus vacated. Fifteen years is a short time—at any rate seems short to those whose journey of life approaches completion, and for whom the abyss into which all must finally plunge is already within easy distance. Yet many changes have occurred even in this short time; and not only have we had losses amongst those who were with us from the beginning, but some of those who joined us later have disappeared from our midst. Some have died; some have left us from age or from ill health; some have transferred themselves to other spheres of usefulness. Our late treasurer, Sir Francis Hicks, under whose reign the present hospital was built, and to whose sagacious energy we are indebted for the carrying out of most of the improvements which I have discussed, died after a short illness nine years ago. Mr. Whitfield passed away a year earlier. Poor old Rainey, whose laborious and useful career among us had extended over so many years, worked with us for a time at this hospital; but he was falling into ill health, and probably few of those who only knew him here could form any conception of what kind of man he had been. He retired on a pension some years ago, and died but recently. Peacock and Murchison are both dead; and it is only within the last few months that poor Frank Mason, whose genial temper and kindness of heart had won for him the warm affection of all his colleagues and of everyone who knew him, whose musical accomplishments were our admiration and delight, and whose eminence as a surgeon was universally recognised, was, to our infinite loss and grief, snatched away by death, in the prime of life, in the fulness of his powers, and when there seemed for him the promise and the assurance of a long and prosperous career. But great though our sorrow is when those we love are removed from among us, Time, the healer, brings its compensation in the hallowed memories that remain when the sting of loss is no longer acutely felt. And irreparable though our loss may seem when eminent colleagues and great teachers depart, they are yet not wholly lost to us, for their names, their examples, and their works survive and add accumulating lustre to the school which they adorned.

I have now completed, however inadequately, the task which I had set before myself; and it only remains for me to give, on behalf of myself and colleagues, a cordial welcome to you who come among us to-day for the first time; to advise you to do your duty, and work systematically at your studies, for you have much to do and little time to do it in; and to urge you here and in the future to show yourselves worthy heirs of those proud traditions which are the common heritage of all who join our ancient hospital and ancient school; and lastly, to thank you, Mr. Treasurer, and you my audience, for the kind patience with which you have listened to my address.

ON BASIC TUBERCULOUS PHTHISIS.

BY PERCY KIDD, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN AND PATHOLOGIST AT THE BROMPTON HOSPITAL.

(*Concluded from p. 617.*)

Cases where the Physical Signs were at first confined to the Base. Post-mortem: Oldest Disease at the Apex.

1. G. W ---, aged twenty-one, engineer, admitted in August, 1883. Family history of phthisis very marked. Winter cough for three years. Continued cough and symptoms of phthisis for two months. At right posterior base, dulness, bronchial breathing, and scanty subcrepitant rales; at left base a few similar rales. Gradual extension of disease, and death from pneumothorax one month later.

Necropsy.—Lobular caseous infiltration of right upper lobe, with a small cavity at the apex, which had perforated the pleura. Lower parts of lung showed a massive catarrhal pneumonia of a greyish pink colour, marked with small yellowish spots. Left lung showed scattered nodular

disease only. The disease was evidently oldest in the right upper lobe.

2. E. B——, aged thirty-four, female, admitted in July, 1883. Winter cough for two years. Slight hæmoptysis in the summer of 1882. Cough worse since her confinement in March, 1883, and several attacks of hæmoptysis. At right posterior base dulness and crepitation; in the left interscapular region some crepitation also. The diagnosis at first was "chronic pneumonia," but was soon altered to "phthisis." The patient died in November, 1883.

Necropsy.—The right lung contained a large apex trabeculated cavity with several small cavities in upper lobe. The lower parts were studded with tuberculous nodules, but contained no cavities. The left lung showed similar but less advanced disease, with one small cavity at the apex only.

3. H. N——, aged thirty-seven, female, admitted in September, 1883. She had pleurisy thirteen years ago; cough and expectoration for nine months. At the right posterior base there was slight dulness and subcrepitant râles. Gradual extension of disease, and death from pneumothorax in March, 1884.

Necropsy. Right upper lobe entirely excavated. A large cavity at the apex of the lower lobe. The rest of the middle and lower lobes was studded with caseating nodules, and contained a few small cavities. The left apex contained one small cavity, and was very fibroid and studded with some old dry caseous nodules; the rest of the lung was spongy, and contained a few tuberculous nodules. There was one small cavity in the lower part of the upper lobe. The oldest disease here seemed to be situated in the right upper lobe.

Cases where the Physical Signs were most marked at first at the Base, but were present also at the Apex. Post-mortem: Oldest Disease at the Apex.

1. T. M——, male, aged fifty-two, admitted in October, 1884. His mother died of phthisis. The patient had been ailing for three months, and had had cough, expectoration, &c. At the left posterior base, dulness, bronchial breathing, and subcrepitant râles; a few similar râles at the left apex also. The disease extended gradually, and the patient sank.

Necropsy.—Pleura over left lung much thickened along the posterior border; left upper lobe fibroid posteriorly, and studded with caseous nodules; at the apex a large trabeculated cavity; anterior parts spongy, but contained some tuberculous nodules; lower lobe fibroid at its apex, and contained a small cavity; remainder of lobe spongy and studded with a few nodules. Right lung emphysematous; it contained a few scattered nodules, most abundant at the upper parts. Disease most advanced and oldest at the apex of left upper lobe. Old disease also at apex of lower lobe.

2. E. M——, female, aged forty-three, admitted in February, 1886. Had suffered from occasional winter cough for some time; for the last nine months continued cough and expectoration. Physical examination revealed contraction of the left side; dulness throughout, most marked at posterior base; breath sounds weak over front and at posterior aspect of apex, with increased vocal resonance. Behind, at the base and lower interscapular region, there were intense cavernous signs, amphoric breathing, and gurgling râles. On the right side the breath sounds were exaggerated. The case was thought to be possibly an empyema communicating with the lung, or fibroid disease of the base and bronchiectasis. The patient died suddenly from profuse hæmoptysis.

Necropsy. The apex of the left lung contained a very old cavity, with dense, blackish, fibroid walls, and the pleura in this region was very much thickened. The bronchus leading to the cavity was greatly constricted by the fibroid growth. The lower lobe contained numerous cavities of more recent date, and the lung was studded with numerous nodular caseous masses. A ruptured pulmonary aneurysm was found in one of the cavities in the lower lobe. The right lung was spongy, but contained some tuberculous nodules.

A consideration of the foregoing cases will show, I think, how easily an erroneous estimate of the proportion of basic to apical phthisis might have been framed if the clinical investigation had not been supplemented by post-mortem examination. To Cases 1 and 2, which I described first, six or seven others might have been added in which the clinical evidence of basic phthisis was fairly strong, and the number of basic cases then would have appeared to be at least eight in a total of 412, or about one in fifty. The fact that physical signs of disease are at first limited to the base, or are more marked here, does not prove that the disease has originated in this position, and does not preclude the existence of older lesions in the upper parts of the lung. In making post-mortem examinations of cases of phthisis it is not uncommon to find that one lung is apparently healthy, whereas, on making the usual sections of the organ, deeply seated nodules or even cavities are discovered, surrounded by healthy lung. Such lesions are usually not recognised, and often cannot be detected during life. The existence of cavities of considerable size in the apex of the lung may be masked by other conditions—e.g., great thickening of the pleura, rigidity of the walls of the vomica, or, what is still more important, narrowing or obliteration of the bronchus leading to the cavity. It must be remembered that cavities and other diseased conditions of the apex are much more likely to escape detection than similar lesions of the base. At the lower part of the lung the respiratory current is extremely vigorous, owing to the proximity of the diaphragm and the greater range of expansion possessed by the chest walls in this region. On the other hand, the circulation of air in the apex is much less forcible, as the result of its greater distance from the diaphragm and the comparatively unyielding nature of the upper part of the thorax. If, in addition to these natural disadvantages, the elasticity of the apex is impaired, there must be a corresponding weakening of the respiratory current in this part of the lung. When excessive secretion accompanies such a transformation of the apex, as is so commonly the case, we have the effects of obstruction of the bronchus superadded to the diminished expansion of the lung tissue, and there may be no auscultatory signs to help us beyond weakness or absence of the respiratory murmur. This condition is more likely to be produced where there is a permanent obstruction of the bronchus in question from surrounding fibrous contraction or from other causes, which need not be discussed here.

It remains now to account for the presence of marked physical signs at the base in those cases where old apex disease gives no evidence of its existence. The physical signs are probably the result of a congestive or inflammatory condition associated with œdema, and at times with partial collapse, of the lung. The lower lobes are known to be specially prone to such affections, and the lungs of persons that are already the subjects of tuberculosis are more liable to intercurrent congestions than healthy lungs. The presence of scattered tuberculous nodules might of course give rise to a localised congestion, but I do not think it is necessary to assume the existence of actual tuberculous lesions at the base in all such cases. This view receives some support from the analogy of pleuritic effusion in phthisical patients. Clinical and post-mortem experience would seem to show that such pleurisies are by no means invariably tuberculous. It is difficult to see why the disease departed from its usual order, and selected the base as its starting-point in Cases 1 and 2. As far as could be ascertained, there had been no previous affection of the lung that could have impaired the vitality of the base in either case, though such an explanation is naturally suggested at first. In both instances the patients stated that they caught cold some few months previously, and never recovered from the effects of it. It may be that the initial affection was a simple congestion or pneumonic attack of the base, which prepared the soil in this region for tuberculous infection. I cannot believe, however, that this is the whole explanation; for on this supposition basic phthisis should be of more frequent occurrence than it actually is. It would be admitted, I think, that a history such as this is not uncommonly given by phthisical patients, in whom it is the rule to find the disease limited to the apex at the outset. It is worthy of note that both the cases described were men. Dr. Pollock (*loc. cit.*) mentions that of the sixty-four cases in which he found the base most affected fifty were males.

The special incidence of phthisis on the apex of the lung has yet to be adequately accounted for. It is unnecessary here to enumerate the various explanations that have been suggested, none of which are entirely satisfactory. There is certainly much evidence in favour of the view that phthisis, in most cases at least, is the result of the entrance of a virus into the lung through the respiratory passages, though it is probably an indispensable condition that the lung shall be in some way prepared for the reception of the

Solly Le Gros

poison. If this be so, it is not unlikely that the phthisical proclivity of special regions of the lung will be found to depend, in part at least, on certain peculiarities of the corresponding bronchial tract. In his monograph on 'Pulmonary Hæmorrhage," Dr. Reginald Thompson makes a remark which I think suggests one factor in the case. In speaking of the respiration of the upper lobe, he says (p. 23), "The bronchial tubes of this lobe, which are not altered in size, remain permanently open, and do not filter the air in the same way as the bronchial tubes of the lower lung." If we compare the slight expansion of the upper lobe which takes place in ordinary respiration with the free expansion and contraction of the lower lobes depending on the immediate action of the diaphragm, assisted by the elasticity of the lower thoracic walls, we must acknowledge the truth of Dr. Thompson's statement. The bearing of this fact on the direction most likely to be taken by particles inhaled into the air passages is obvious.

In conclusion, it may be said that the cases which have been related show that the diagnosis of basic phthisis is not so easy as would appear to be the case at first sight. There are several diseases of the base which cannot always be distinguished from tuberculosis by the ordinary methods of examination. Without attempting to discuss the diagnosis of these various diseases, I would strongly urge the importance of a routine examination of the sputum in all such cases. I could quote instances where a most unexpected light was thrown on the case by this means. True basic tuberculosis is extremely rare; I believe it is even rarer than it is commonly thought to be; whereas the base is specially prone to other affections. I would suggest that the question which has been discussed not only possesses pathological interest, but has also a distinct bearing on the prognosis of certain cases. Keeping in mind the extreme rarity of primary basic tuberculosis, we may reasonably hope that a given case of localised disease of the base is not tuberculous, and if we fail to discover tubercle bacilli in the sputum on repeated examination, our hope becomes almost a certainty. But inasmuch as non-tuberculous disease of the base may be complicated by the supervention of tuberculosis, as in four of the cases that have been described, it is well to examine the sputum at intervals, even when we are satisfied in the first instance as to the non-tuberculous nature of the case, especially if the patient's progress be unsatisfactory. It may be said that the prognosis of chronic disease of the base is generally unfavourable, and this is true up to a certain point; but if tuberculosis can be excluded, a more hopeful prognosis may generally be given.

Brook street, W.

SOME REMARKS ON THE OPERATIVE TREATMENT OF CHRONIC OBSTRUCTION OF THE SMALL INTESTINE.

BY R. L. KNAGGS, M.A., B.C. CANTAB., F.R.C.S. ENG.

THOUGH intestinal obstruction has been brought prominently forward of late years at the Societies and in the journals, the operative treatment of chronic obstruction, when the small intestine is the seat of the disease, has attracted but very little notice. This may result from a feeling that was expressed in 1868 by Dr. Fagge, that "contractions[1] are *par excellence* the cases in which an operation must necessarily fail." But a study of Dr. Fagge's own cases—sixteen in number, three of which were hopeless cases of malignant disease—shows that there were no less than nine in which modern surgery might have interfered, otherwise than by a palliative enterotomy, with some prospects of success. It is true post-mortem records may appear to lend themselves to surgical ideas with much greater ease than the cases themselves would have done, but, after making some allowance for this, there would still remain a considerable proportion not beyond the surgeon's aid. This fact alone is sufficient to justify exploratory laparotomy in all cases of obstruction from contractions which are not obviously hopeless.

But though exploration is not unfrequently undertaken, it seems generally to end in an attempt to obtain relief by enterotomy only, or further action is altogether abandoned. Now, though this operation in the majority of cases can only be expected to be palliative, it occasionally proves to be of greater value, as will be seen from cases quoted further on. Its *modus operandi* is probably to relieve the distension above the obstruction—a condition which in not a few is sufficient to cause complete occlusion of the intestinal canal; and when by this relief the channel is once more opened, the intestinal contents are enabled to pursue the normal course, care in diet and medication being quite sufficient to prevent a fresh accumulation taking place. But these cases can hardly be considered to be free from the danger of a fresh obstruction occurring at future dates; though, should that happen, the reopening of the old wound would probably be all that was needed for their relief.

So few cases of operation bearing upon this form of obstruction have been recorded during the last seven years that the following are all that have been obtained from the different available sources.

1. Mr. Sidney Jones[2] records a case of chronic obstruction resulting from localised peritonitis, consequent upon ovariotomy performed four years previously. Enterotomy was performed after abdominal section, the artificial anus being 29 in. from the ileo-cæcal valve and the intervening coils, and the cæcum "being matted together by glandular and inflammatory infiltration." The patient survived three weeks.

2 and 3. Dr. Malins[3] records two cases in which obstruction occurred from adhesions of the intestines from pelvic inflammation. In one laparo-enterotomy was performed with success, and the artificial opening closed spontaneously, the natural passage becoming restored. In the other the same operation was adopted, but first some adhesions were separated. When reported, the bowels acted weekly, and the artificial anus, though diminishing, had not closed.

4. Mr. Treves[4] records the case of a woman upon whom he operated for obstruction three months after the reduction of an inflamed hernia. Laparotomy was performed, and a distended coil was found adherent in a bent position close to the femoral ring. The adhesions were broken down, and the case did well.

5. Mr. Meredith,[5] at the Clinical Society, recorded the case of a woman in whom intestinal obstruction set in a week after ovariotomy, which had been complicated with general adhesions. Laparotomy was performed early, and two separate coils of intestine were found kinked and obstructed by the traction of two separate omental bands. These were released, and the patient was in good health six months after.

In these few cases enterotomy has certainly played a successful part, but such success is exceptional and cannot be held to justify the employment of enterotomy in the hope of its being a curative procedure. The attempt to remove the obstruction by the separation of adhesions alone was made in two cases, but one, being an example of acute obstruction, perhaps hardly comes within the scope of this paper. No record of resection of the intestine for this condition, except Koeberlé's case (*vide infra*) has been found; and yet it is particularly applicable, as Mr. Treves has pointed out, for those cases where the obstruction is due to the effects of a contracted mesentery.

In Dr. Fagge's forty-ninth case[6] the cause of the obstruction "was found in a mass of rounded tubercles in size from that of a pigeon's egg to a nut. These formed collectively a mass as large as a small fist, situated in the mesentery close upon the intestines, and the surrounding inflammation, which appeared to have been long passed, had by contraction produced much puckering, shortening, and thickening of the mesentery, and so complete a stricture of the intestine that scarce room was left for the passage of a small quill." Here is a case in which resection seems to be specially indicated; whilst in the preceding one (Dr. Fagge's forty-eighth case), though several feet of bowel were implicated in the obstruction, which was also due to disease of the mesenteric glands, the same operation might also have been found possible; and in considering the propriety of resection in any particular case, it may be remembered that as much as two yards of small intestine have been successfully removed by Koeberlé.[7]

Cases may occasionally present themselves in which relief

[1] The term "contractions" includes several pathological conditions—such as matting of intestine, kinking by traction of adhesions &c., adhesions compressing the gut, and shrinking of the mesentery. Though "contractions" practically comprise all cases of chronic obstruction of the small intestine, three of Dr. Fagge's cases affected the large intestine.

[7] Treves on Intestinal Obstruction, p. 477.

may be afforded by some exceptional method, which the condition of the parts will suggest. Such would Dr. Fagge's fiftieth case seem to have been. In this, "three feet from the cæcum a portion of small intestine, not more than an inch in length, was pale, empty, and contracted. Opposite the constricted point the mesentery contained a group of enlarged strumous glands, the largest the size of a walnut, filled with chalky matter. It appeared as if these glands, more particularly the largest, had by their growth and increase drawn a portion of mesentery backwards to the spine, and thus, by expanding the two layers of the serous membrane and widening the base of the peritoneal ligament, had acted like a broad ligature." Here, though somewhat contracted, the channel was not completely obstructed, and it is possible that the less serious operation of enucleation of glands might have removed both the obstruction and the disease. Now, although a fair proportion of cases of "contraction" might be satisfactorily treated either by enterotomy, which might lead to cure, or by division of adhesions, or by resection, or possibly by some other method which particular conditions might suggest; yet there will be met with cases in which the second and third plans can hardly be entertained because of the large amount of bowel implicated, or the intimate nature of the adhesions between the matted bowel and other parts, or perhaps for other reasons.

In the *British Medical Journal* of Feb. 13th and March 13th, 1886, cases of pyloric stricture are recorded by Mr. A. E. Barker and by Mr. T. H. Morse of Norwich, in which it was attempted, in one case with success, to open a fresh path for the passage of alimentary matters by uniting an opening in the jejunum with an opening in the stomach. This idea, apparently new to English practice, is capable of a much wider application, and it is probable that it may be found of use in dealing with certain cases of contractions not amenable to the two methods just alluded to, and yet in which enterotomy, with its attendant discomforts and probable evils, should be avoided if possible. It must be remembered that in the latter operation, in these cases, the small intestine may be opened, either of necessity or by accident, high up; and that if the fæcal fistula does not close, the whole or a part of the contents of the intestine are discharged from the body in a very imperfectly digested state.

Quite apart, then, from other discomforts which are likely to be present, the results of malnutrition will not be long delayed, and the patient may die of inanition as the result of an operation undertaken in the hope of saving his life. If, however, a connexion can be made between the intestine above and the intestine below the obstructing coil or coils, a fæcal fistula is avoided, and the absorbing power of the intestine below the obstruction is still utilised. Moreover, in some cases the coils constituting the obstruction may be rendered useful; for the distension above them, being relieved entirely at the operation, would be prevented from again taking place, and the passage through the obstruction might possibly be reopened and kept patent. The intestinal contents, having a choice of two ways, would probably make use of both, and in the event of any renewal of obstruction occurring, or should the original track remain impervious, the artificial deviation would become the regular channel. It might act either as a safety valve, as a colotomy wound has been known to do, or it might replace entirely the normal canal. By this operation extensive division of adhesions between coils, and between coils and the parietes, might be avoided, and less risk would be run of fresh adhesions forming and a similar state of affairs resulting. The obstruction would be overcome without interfering with its cause—a point of considerable importance, and one which hitherto has only been accomplished by enterotomy, to which there are grave objections. Lastly, it is interesting to note that Nature has herself solved the difficulty in this very way, though in Nature's cure there existed imperfections that art might hope to avoid. The case referred to is the well-known one recorded by Mr. Birkett.[8] In this case a loop of small intestine contained in a strangulated inguinal hernia, which had been reduced, was found to have become adherent, and narrowly constricted at the site of the neck of the sac. A communication had formed between the adherent coils above the constriction, and this communication had served as the channel for the passage of the contents of the small intestine. Death was caused by extravasation of fæces through the breaking down of some of the adhesions.

(To be concluded.)

Dolly Le Gros.

TROPICAL ABSCESS OF THE LIVER.[1]

BY SURGEON A. TOMES,
INDIAN MEDICAL SERVICE.

THE term "tropical" applies to those large, usually single, but frequently multiple abscesses of the liver which are met with in persons who reside in the tropics, or who have been subjected to tropical influence at some period of their lives, and which are the result of a parenchymatous inflammation of the organ induced mainly by such influence. The disease is now so well known and recognised as an independent affection that further definition is unnecessary. On the average, hepatitis causes every year 1600 admissions to hospital, from 70 to 80 deaths, and from 160 to 200 invalidings, in the British army in India, consisting of 56,000 men. This heading includes many cases of "liver" that do not go on to suppuration, but the deaths are to be attributed to abscess.

In the Bengal army, with a strength of from 35,000 to 38,000, the average annual admissions for the five-year period 1877-81, for liver-abscess alone, amounted to 63. Broadly speaking, the admission-rate for hepatitis in the army in India is over 28·9 per 1000 of strength, the invaliding rate 3·03, and the death-rate 1·13, the admission-rate for abscess in Bengal being 1·8 per 1000. All parts of the peninsula are not equally unhealthy in respect of hepatitis. The Madras Presidency comes first and Bengal follows. In 1883 the mortality was distributed thus:—Madras army, 1·72 per 1000; Bengal army, 1·06; Bombay army, 0·82.

It is open to doubt whether army returns fairly represent the liability of Europeans generally, irrespective of class or occupation. The proportion of admissions to hospital for hepatitis to total admissions is 2·1 per cent. in the army. What it is in civil life I have not been able to ascertain. Nor have we the means of determining the liability according to class. My own impression is that no great difference obtains, if any, in respect of class or occupation. Cases of abscess are constantly being reported from civil practice, and for every one so recorded there must be many that we hear nothing of, while every case is recorded in the army.

The next question is, to what extent is the native of the country liable? It was formerly supposed that he enjoyed almost complete immunity. Everyone who has had experience in native practice must be aware that this is not the case. That hepatitis is far less common in the natives than in foreigners is strikingly shown by the accompanying figures for 1883.

	Admissions per 1000.	Deaths per 1000.
British army (51,673)	1692 = 28·9	63 = 1·13
Native army (114,830)	173 = 1·5	21 = 0·18
Native gaols (88,174)	87 = 1·0	19 = 0·22

While in British military hospitals the proportion of admissions for hepatitis to total is 2·1 per cent., in native military hospitals it is only ·16 per cent., and in native gaols ·09 per cent.

My experience leads me to believe that the disease is not necessarily so rare among natives in civil life as these returns show it to be in the army, and that its prevalence varies according to season and locality. I am of opinion, too, that liver abscess in the native has a somewhat different mode of origin, being exclusively due to climatic influence, and independent of habits of life. It occurs in the native as a late result of general constitutional decay from prolonged malarial poisoning. The subjects have invariably been exposed for a long period to malarial influence, and are the victims of a profound cachexia. In Europeans, on the other hand, the liver appears to be excited to inflammation under short exposure to local influence; more than 50 per cent. of the cases occur during the first four years of residence. The attack may be of a splenic type in the European, but it is low and insidious in the native. It is a more serious affair in the latter, and the mortality per cent. of those treated is higher. In a vast country like India climates of every degree of unhealthiness are to be found; and malarious districts, from topographical or meteorological causes, are subject to changes in the intensity of the endemic incidence. A notable example of such a phenomenon has occurred during the past ten or fifteen years in Bengal. Since 1870 a portion of that

[1] Read before the Middlesex Hospital Medical Society.

province has become decidedly more unhealthy from malaria. A kind of epidemic wave passed over the tract from north to south-west, involving in its course the district of Midnapore. The result of the invasion is that the inhabitants now bear the impress of the noxious influence in a marked degree, in the shape of enlarged spleens, anæmia, bowel complaints, and cachexia generally. Dispensary records also show an increase in admissions for liver abscess coincident with the increased prevalence of fever. While civil surgeon at Midnapore, I treated there, in the three years 1882-84, no less than twenty-one cases, all in natives. Local practitioners informed me that in former times the disease was practically unknown.

In Europeans the greatest liability occurs between the ages of twenty and forty-five. Abscess has never yet been met with in any person, native or European, below fifteen, and it is rare above fifty. In childhood it is absolutely unknown. Among Europeans men are more liable than women.

British Army in India, 1883. Hepatitis.

	Admissions per 1000.	Deaths per 1000.	Admissions per cent. of total admissions.
Men (54,000)	39	1·41	2·1
Women (2200)	15·5	·91	1·8

The disproportion is still more marked as regards abscess itself. In Waring's 300 cases 9 only were in women, and out of 82 cases reported in various journals 2 only were in women. On the other hand, out of 23 cases in Europeans and Eurasians treated at the Presidency Hospital, Calcutta, as many as 15 were females. The proportion of females to males among the British-born population in India is 1 to 7. I have reason to believe that owing to the exclusive climatic mode of origin in natives there does not exist the same difference in liability of the sexes as in Europeans. Among my 21 cases, mostly dispensary patients, 3 were females; and bearing in mind that the population of females to males attending dispensaries in Bengal is about 1 to 6, this, as far as it goes, does not indicate any very great irregularity.

Authorities are agreed that suppurative hepatitis in Europeans in the tropics is mainly due to the effect of climate. But intemperance, over-indulgence in animal and highly spiced foods, and indolence, are spoken of as predisposing causes in the individual; while exposure and chills are frequently noted as exciting causes. I am quite disposed to admit that chill or exposure starts the attack in many instances; this is clearly the mode of origin of many of the reported cases. But have we sufficient evidence of the part the other conditions play in the production of the disease? The great difference in the liability of the two races is attributed to the variation in the nature of diet and drink, but it may equally be due to difference in degree of acclimatisation. The great reduction in liver diseases in the army is as likely due to improved sanitary arrangements and protection against climate as to the steadier habits of the men. I am inclined to think that the "intemperate" theory, at all events, has been made too much of. An examination of reported cases throws very little light on the subject, because complete histories are so rarely given. It is a significant fact, however, that out of 425 cases of hepatic abscess, including Waring's 300 and others from the journals, the subjects were said to be intemperate in 50 instances only. Whatever influence personal habits may have, the fact remains that, quite independently of any of them, when an inhabitant of temperate climates goes to reside in the tropics, there is a tendency for his liver to become disorganised, though fortunately this actually occurs in a relatively small proportion only. This applies to the dark races as well. Natives of mountain regions in India, on taking up their abode in the steamy plains of Bengal, are said to become liable to hepatic abscess. Change of climate affects hill cattle in the same way. Imported horses suffer to a large extent; the death-rate from hepatitis among troop horses in India amounts to 2 per 1000 (Collins).

What is the particular element or combination of elements in a tropical climate that induces hepatic disease? It cannot be heat alone; liver abscess is least common in such parts as the Punjab, Central Provinces, &c., where there is greatest heat. Nor is it malaria alone, for the disease is unknown in malarious parts of the temperate regions of the world. The distribution of hepatitis according to district points to a combination of moist heat, dampness of subsoil, and concentration of malaria as the condition most favourable to its production. Still there is something over and above this in the climate of India that we do not understand. An exactly similar combination exists in the West Indies, though the disease is not so frequent there (in the proportion of 1 to 4).

Dr. Budd's now obsolete theory of the dependence of tropical abscess upon dysentery only requires a passing notice. It is unsupported by clinical observation, statistics, and post-mortem examinations. Dysentery being a disease caused by similar conditions of climate, very frequently complicates liver abscess, and a very serious complication it is, but there is no causal relation between the two. Their concurrence in the same individual is a pure coincidence. It is important to remember that the signs and symptoms even of the hepatitis that precedes it, and of the abscess itself, are apt to be ill marked and insidious; they often escape notice, or some or all of them may be absent. It has been estimated that they are well marked in 8 per cent. only, while the abscess runs a perfectly latent course in 13 per cent., even in Europeans. Instances are on record where the subjects were engaged in their usual occupations up to the very last. Soldiers have been on full duty up to a few hours of death by the bursting of an abscess internally. In one case an abscess burst while the man was actually on duty. The signs which if a given case of hepatitis lead to suspicion of suppuration are: The enlargement of the liver, which loses its uniform contour and develops more particularly in some one direction so as to form a bulging; localisation of pain and tenderness; pleuritic or peri-hepatitic friction; rigors, chills, sweats, and most important of all the temperature. Several apyrexial cases are on record, but I cannot conceive suppuration occurring without the temperature being affected at some time or other. A careful scrutiny of the temperature range, auscultation, and bilateral measurements of the chest are called for. The temperature must be taken every hour, so that a complete reading for the twenty-four hours may be obtained. Subjects of liver abscess are frequently also suffering from malarial fever. A want of periodicity and a resistance to quinine will indicate hepatic origin.

By combined statistics the mortality of unrelieved hepatic abscess is found to be about 90 per cent. Death occurs with or without rupture. About one-half of all abscesses that are left alone remain intact. Spontaneous evacuation through the lungs occurs in about 20 per cent., less than half of which recover. Out of 33 cases that recovered spontaneously (Waring's and others), 16 burst into the lungs, 8 into the intestine, 1 into the stomach, and 2 ended apparently in spontaneous absorption. The extent to which an abscess will develop is surprising. The contents are sometimes to be measured rather by quarts or gallons than by ounces. The whole organ may be converted into a bag of pus. In one case 17 pints were found at the post-mortem examination. I have myself removed as much as 80 oz. at a single operation; while 200 oz., 400 oz., and even 1000 oz. represent the aggregate amounts removed by successive tappings by others. These enormous collections are mostly seen in natives, who are apt to apply for treatment only at too late a stage of the disease.

Solitariness is a character of tropical abscesses, but they are often multiple. In Waring's 300 cases they were solitary in 62 per cent., multiple in 37·8 per cent. Multiplicity is explained by the mode of origin. The disease begins as multiple foci of softening. The foci coalesce as they increase in size. If the areas coalesce into one, a single abscess results; if they combine in groups, the abscesses will be multiple.

(To be concluded.)

TWO CASES OF ABDOMINAL SECTION.

BY A. S. UNDERHILL, M.D., M. CH., S.S. CERT. CAMB.,
SURGEON TO THE GUEST HOSPITAL, DUDLEY.

RECENTLY I have had two cases in which I performed abdominal section, and as these—although fatal—possess points of clinical interest I venture to record them.

CASE I. *Rupture of a Tubal Pregnancy.*—M. I ——, aged twenty-two, married eighteen months, one miscarriage at eighth week, a florid, healthy-looking woman, had catamenia regularly till seven weeks ago, when she was suddenly seized with acute pain in the abdomen, referred chiefly to the region of the right ovary, which continued for about

ten days, leaving her fairly convalescent at the end of two weeks. As she was feeling stronger, she walked for some little distance, but on her return home was again seized with the acute pain over the right ovary, became perfectly blanched, staggered to a sofa, and was profoundly collapsed for about twelve hours; from this condition she very slowly recovered, and still referred all her pain to the right side of the lower abdomen. On vaginal examination I found the os and cervix uteri œdematous and very tender, but unlike what is usually found in commencing pregnancy, the uterus was fixed and deflected to the right; posteriorly there was a tender semi-solid mass; abdominal percussion—as far as could be ascertained on account of the tenderness gave a duller note than normal from the groin to the umbilicus on both sides. Her condition during the next twelve days was very unsatisfactory. She had a recurrence of peritonitis, and suffered most distressing pain. Her pulse was never under 140, and her temperature averaged 103° F. Neither herself nor relatives would consent to any operative interference. On the fourteenth day her symptoms became aggravated, and as she would evidently sink before many hours elapsed, permission was given for abdominal section.

On opening the abdomen in the mesial line about a pint and a half of very dark-coloured serous fluid gushed out. On the right side the uterus was bound down by adhesions and coagula to the brim of the pelvis. The right broad ligament was a mass of coagula, the Fallopian tube being much thickened and enlarged; the left broad ligament was encased in coagula, but it was impossible to recognise the Fallopian tube; the intestines at the lower part of the abdomen were matted together by inflammatory adhesions. To appearance and touch much of the coagula resembled placental tissue, but nowhere could I find a trace of an embryo. I removed as much of the coagula as possible without injuring the intestines, thoroughly washed out the cavity with warm water, and inserted a glass drainage-tube into the pelvis. She rallied well from the operation and suffered little pain. On the eighth day, however, she died, obstinate constipation and vomiting being the predominant symptoms.

In my opinion the patient had a right tubal pregnancy; the first attack of peritonitis killed the ovum, which burst after the exertion of walking, and so caused the hæmatocele. If at this time consent had been obtained for the operation her chances of recovery would have been more promising; but on the fourteenth day fresh bleeding took place and handicapped the operation, from which she had not sufficient strength to rally. Under similar circumstances I should not hesitate to advise an early operation, as I think I might promise a fair relief from pain and a probably favourable result.

CASE 2. *Cystic Degeneration of both Ovaries with an old Hæmatocele.*—M. C——, aged forty-two, married, with six children, nine months ago was attended by a midwife, who delivered her after a very severe labour. Some weeks afterwards, not feeling strong and suffering great bearing-down pains and pain in defecation, she consulted a medical man, and was treated by rest in the recumbent position and tonic medicine, but not feeling much better she was admitted under my care into the Guest Hospital. I found the uterus retroflexed, but fairly movable on the sound. Posteriorly, in Douglas's pouch, there was a tense swelling, somewhat caudate in shape and very painful on pressure. Per rectum it was more defined; over both ovarian regions there was considerable tenderness, so much so that it was impossible to ascertain their condition. She could not walk or stand without much bearing-down pain, and she had occasional attacks of obstinate vomiting; the temperature was normal. Permission to explore the abdominal cavity could not be obtained; I therefore treated her with morphia suppositories and mild aperients, keeping her entirely in bed, considering that hers was a case of pyosalpinx very full coming on after delivery. As she did not obtain the relief she anticipated, she left the hospital at the expiration of three weeks, but returned after two months, during which time she had had no cessation from pain, and had lost 12 lb. in weight.

As the patient was now quite unable to do anything, and was evidently becoming worse, after consultation I performed abdominal section, and found the right ovary considerably enlarged and full of cysts; the left ovary was also in a state of cystic degeneration, and bound down firmly in the recto-vaginal cul-de-sac. On removing it, a small cyst which was adherent burst its contents being lost in the pelvic cavity. On rectal examination, directly after its removal, the caudate swelling could still be felt, tense and firmly adherent, evidently an old hæmatocele, which had become partially absorbed, and was now organised. In both instances the Fallopian tubes were intact. I thoroughly washed out the pelvic cavity with warm water; and as hæmorrhage was very slight, I did not resort to drainage. She passed a fair night, but never completely rallied from the shock, and died twenty-eight hours after the operation.

No post-mortem examination was allowed, but I examined the wound, and found that there had been no bleeding; the stumps of the appendices were healthy-looking, and, as far as I could ascertain, there was no appreciable cause for her death except exhaustion. Had she consented to the operation when it was first proposed, I feel assured that her life would have been saved. I have twice operated on more seemingly unpromising cases with favourable results, but this patient was of a depressed, nervous temperament, and greatly dreaded the operation, making her on this account a very unfavourable subject. The case was of interest on account of its diagnostic difficulties, as the swelling was in shape, position, and history typical of what is usually found with pyosalpinx.

Tipton, Staffs.

A CASE OF RAPID PLEURAL EFFUSION TREATED BY ANTISEPTIC INCISION.

BY ALBERT WILSON, M.D.

THE following case is of interest, as it shows the advantage of an incision made during the early stage of pleural effusion before it had become a case of empyema. In fact, the effusion was so large and so rapid, and the dyspnœa and cardiac depression were so great, that the case would never have reached the stage of empyema if prompt operative treatment had been delayed.

The patient, Mrs. B——, aged thirty-five, was first seen by me on March 3rd, 1886. She complained of breathlessness and increased cough, and she had been ill nearly a week. There had been no rigors; the pulse was 140, small and weak; the expectoration was mucous, slightly rusty; respiration 40; temperature under the tongue 102°. On examining the chest, the left base was dull on percussion. The front of the chest was normal in all respects. Auscultation: At the right base there were moist râles and crepitations; at the left base there were no respiratory sounds audible; vocal resonance was increased over the right base, whilst it was ægophonic over the left base; vocal fremitus was increased over the right base, but absent over the left. The absence of vocal fremitus decided the diagnosis as pleurisy and pneumonia.

March 4th.—The dulness is higher posteriorly, and in the axillary line there is also dulness in front from the left side when she sits up. The first sound, which is weak, is loudest behind the sternum. Temperature 101°; pulse 140; respiration 46.

5th.—General condition worse and increased effusion. Absolute dulness at and below the third rib in front, and from a line parallel with the fourth dorsal vertebra behind. The right chest is normal, except for cardiac dulness over the fourth right costal cartilage. The apex of the heart is now almost under the right mamma. There is a total absence of respiratory sounds all over the left chest, both back and front, except above and just below the clavicle. Œgophony is well marked at the angle of the left scapula, the vocal resonance is altered in front, vocal fremitus is absent on the left side, and there are moist sounds over the right base. Temperature 101°; respiration 48; pulse 140. The pulse tracing shows a very small wave, due to the feeble cardiac impulse and the contracted arteries. Operative treatment was now imperative. Being a disciple of Lister, I did not feel justified in opening this large cavity without the spray, as it was a small foul room, and the impure air entering the pleural cavity would be very dangerous and certain to cause suppuration. Further, to wash out the cavity, which I had allowed to become septic, would be an unnecessary labour for me, and a needless and rather dangerous entertainment for the patient. I preferred prevention to cure. I made an incision between the seventh and eighth ribs posteriorly to the axillary line. Clear serum poured forth in abundance; more than five pints were

Solly. Le Grow

collected and about a pint was wasted. Air entered the chest freely. When I introduced my finger through the ribs, I could not reach the lung for at least half an hour after the incision was made. When the lung did expand the surface of the pleura was found to be quite rough. A tube four inches long was inserted downward and backwards, and I applied a small dressing of boracic lint soaked in mercurial solution. Within an hour the heart sounds were to be heard under the left breast. Friction was heard posteriorly as soon as the pleural surfaces were apposed. The friction gradually appeared from above downwards, as the expansion of the lung was very gradual, and when I left it had not fully expanded at the base, which I proved with my finger. The pulse tracings, taken every few minutes, were very interesting. Before the operation it was a slight deviation from a straight line, being so feeble. Soon after the operation the pulse wave expanded, getting larger and fuller until there was a full, sharp, apex systolic wave with a marked dicrotic wave, showing low arterial tension, due to the relaxation of the arteries and the removal of the pressure on the heart and main vessels.

6th.—Temperature 101°; pulse 120; respiration 32. The wound was dressed under the spray. There was a free serous discharge through the tube, and air enters with inspiration. The physical signs of pleurisy are well marked.

7th.—Temperature 101°; pulse 120; respiration 26. Wound dressed and tube removed. I inserted my finger to feel the pleura. It felt rough and spongy, like the placenta. I passed my finger round, separating the adhesions of the two surfaces, and it reminded me of a case of placenta prævia. It was the adhesion of the surface that determined me to remove the tube.

8th.—Temperature 101°; pulse 108; respiration 26.

10th. Temperature 100°; pulse 98; respiration 24. Wound dressed. Very little thin serous discharges. Physical signs normal over both lungs. I could not trace the cause of the slow fall in temperature. The patient, though very weak, is doing well, considering that she was at death's door before I operated.

15th.—Temperature 99°; pulse 90; respiration 20. Wound dressed and healing satisfactorily. Before the operation I measured each side of the chest from the anterior to the posterior mesial line just below the mammæ. The right half was 16 in., the left 17½ in. To-day, five days after the operation, each side measures 16 in. alike. The spine is perfectly straight, and the left chest is not shrunken. These results could not be attained by aspiration, however skilfully done. The patient was soon restored to perfect health.

Leytonstone.

A CASE OF SUPPOSED FRACTURE OF NECK OF SCAPULA.

By G. Y. EALES, M.R.C.S. Eng., L.R.C.P. Ed.,
HOUSE-SURGEON, TORBAY HOSPITAL; LATE ASSISTANT DEMONSTRATOR OF ANATOMY AT ST. GEORGE'S HOSPITAL; AND SENIOR ASSISTANT-SURGEON, SIRHOWY IRONWORKS.

LAST September R. B——, aged fifteen, a spare, delicate-looking lad, came to me with an injury to the left shoulder. He was playing with several boys, butting at each other with folded arms, when he was knocked over and fell on his left shoulder. On examination I found the following points of observation:—1. Considerable bruising of the deltoid. 2. The acromion process prominent, with depression underneath, and outer third of the deltoid flattened. 3. Arm lengthened about an inch and a half, and drawn away slightly from the side. 4. A rough object high up in the axilla in the neighbourhood of the neck of the scapula. 5. Humerus rotated freely and smoothly, and with but little pain. 6. A round projection in front and below the shoulder, which proved to be the head of the humerus on rotating that bone. 7. On raising this projection upwards, outwards, and backwards, crepitus was produced; the contour of the shoulder was restored, with disappearance of the deformity. 8. Slight increase of vertical measurement around the joint. 9. Great freedom of passive motion, with but little pain.

Owing to the bruising I was unable to manipulate the coracoid process; I therefore put the arm up with a pad in the axilla, with the elbow raised and bandaged to the chest. Five days afterwards, the bruising and swelling having partially subsided, I took off the bandages and found the same condition of things as when I first saw him, but much more plainly. On raising the head of the humerus all the symptoms disappeared, accompanied by loud bony crepitus audible to the bystander; and on removing the reduction force all the above-named symptoms again appeared. I was struck with the ease and comparative absence of pain with which the fracture could be reduced, also the readiness with which it became displaced on removing the reduction force. The rough object in the axilla was now more distinct, and disappeared on reducing the fracture, and was apparently the scapular neck. I now noticed also that the coracoid process did not appear to move on reducing the fracture.

Remarks.—The noteworthy features of the case were (1) the ease with which the fracture could be reduced, together with the ensuing deformity on removing the reduction force; (2) the great freedom of passive motion; and (3) the striking resemblance to dislocation into the axilla. With regard to this latter, the lengthening of the arm, the freedom of passive motion, and the easy reduction of the deformity in the way I have mentioned were sufficient to exclude simple dislocation into the axilla. The other lesions which this injury simulates appear to be (1) dislocation of the humerus into the axilla, with fracture of its neck; (2) separation of the epiphysis of the humerus; and (3) dislocation of the humerus into the axilla, with fracture of a portion of the glenoid cavity of the scapula. The lengthening of the arm and the movement of the head of the humerus on rotation are against the first two. Holmes, in his System of Surgery, states that it is the opinion of most modern writers on surgery that a simple fracture of the anatomical neck of the scapula never occurs, and that Malgaigne has shown that the symptoms of the supposed lesion are identical with those of dislocation of the humerus into the axilla, with fracture of a portion of the glenoid cavity of the scapula. In another place Holmes admits that the two lesions are indistinguishable during life. I hardly dare to express an opinion in the face of such high authority; but why should not a simple fracture of the anatomical neck of the scapula occur as readily as the more complicated injury? because the force to produce either must be of the same nature and very considerable. It appears to me that the symptoms of this case are so analogous to those quoted by Dr. Lotzbeck of Munich[1] and that recorded by Spence,[2] and bearing in mind the fact of the coracoid process being apparently stationary, that I feel justified in saying that in all probability this was a case of fracture through the anatomical neck of the scapula.

The lad having passed from my care and observation for treatment by another surgeon, I am unable to give any details of the progress of the case, but I afterwards ascertained that he eventually gained very good use of the arm.

Torquay.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

WEST LONDON HOSPITAL.

ABSCESSES OF THE NECK AND BEHIND THE PHARYNX, ALMOST CAUSING DEATH FROM SUFFOCATION.

(Under the care of Mr. WAINWRIGHT.)

ABSCESS at the back of the pharynx is a very formidable disease, as is illustrated by this case, and requires the most prompt surgical treatment. The chief danger is that of suffocation, either from œdema of the glottis or the mechanical effect of the swelling. In this case the relief afforded by incision of the external abscess made it probable that the post-pharyngeal abscess communicated with it, but the subsequent progress of the case negatived this view.

[1] See New Sydenham Society's Biennial Retrospect for 1867-8, p. 340.
[2] Edinburgh Medical Journal, 1863.

Simple incision with a guarded knife is usually sufficient to relieve the symptoms; but occasionally tracheotomy may be required, as in a case which was recently under our observation, where the flow of pus from the abscess was so copious as to stop respiration. For notes of the following case we are indebted to Mr. R. Lake, house-surgeon.

On May 10th, 1886, an adult, G. H——, was admitted into the hospital suffering from attacks of dyspnœa. His voice was low and harsh, his face very anxious, and the breathing distressed, with frequent attacks of dyspnœa. On examination of the neck a large fluctuating swelling was found beneath the trapezius on the right side, and on looking into the mouth the pharynx was found bulged out on that side and pushed towards the left. There was much swelling in the right submaxillary region. He gave the following history: The swelling with pain began six weeks previously, and there had been gradually increasing dysphagia, so that for the last seven days he had only been able to swallow fluids. He had had syphilis five years previously, and some months ago a general eruption of rupial character broke out, from which he is still suffering.

An incision was made into the abscess under the trapezius, with antiseptic precautions, and about two ounces and a half of pus let out. This relieved the breathing, and it was hoped that the other abscess would be emptied through this. He was given ice to suck.

May 4th.—At 1.30 A.M. he had become much worse; the breathing stopped entirely for a few moments, and it required artificial respiration to bring him round. An examination was now made with the laryngoscope, and there was found to be a large amount of œdema of the right side of the pharynx and tongue, and a swelling on the same side involving the whole of the right side of the pharynx, and projecting beyond the middle line. This was incised, and about two ounces of fetid pus escaped. The symptoms were at once relieved, and when the patient spoke it was with a voice which was now full and clear.

12th.—A mixture containing ten grains of iodide of potassium was ordered, and he was placed on a diet of meat, and allowed stout. He was able to take solid food for the first time during nine days.

14th.—The incision in the pharynx had closed, and so was reopened, two ounces of glairy fluid escaping.

17th.—The dose of iodide of potassium was increased to twenty grains.

20th. Much better. There is only slight discharge from the incisions.

27th.—The abscesses are quite healed, and the eruption on the body is rapidly improving under large doses of iodide of potassium.

STROUD GENERAL HOSPITAL.

TWO CASES OF EXTERNAL URETHROTOMY.

(Under the care of Mr. STORRY.)

CASE 1.—Walter W——, aged twelve, was admitted on Feb. 26th, 1886. The boy gave a history of having fallen, some sixteen months ago, on some stone steps, the sharp edge of one step having caught him in the perineum. There was at the time of the accident considerable bruising and swelling of the perineum, and blood issued from the meatus on attempting to pass urine. He was unable to micturate, and a medical man was consequently sent for, who passed a gum-elastic catheter, and repeated this operation in a week's time. From this time up to the date of his admission the boy had not sought further advice.

On admission, the urine passed in drops, the boy crying out and straining severely; he complained also of a smarting pain at the back of the perineum. Several attempts were made by Mr. Storry and the house-surgeon to pass an instrument, but without success. External urethrotomy was therefore decided upon, and on March 2nd the patient was etherised with one of Clover's small inhalers; and before operating Mr. Storry tried again to pass a catheter, but this was impossible. Mr. Wheelhouse's grooved straight staff, with the beak turned up as a blunt hook, was passed down to the stricture; the urethra was opened upon the staff, and the sides of the divided urethra being held apart with forceps, the small probe-pointed director was after considerable difficulty passed into the bladder. The strictured portion of the urethra was then divided, and the tapering probe-pointed gorget introduced above the director into the bladder; a No. 8 silver catheter was passed through the meatus upon the gorget into the bladder, and the catheter tied in. This catheter was left for ten days, when a No. 9 silver was passed, the perineal wound having healed by this time. After this a No. 8 silver was passed daily, which after a time was changed for a No. 9.

The boy was discharged on April 12th, a No. 10 silver catheter being passed the same morning. He was told to return in three or four days, but failed to do so until a fortnight afterwards, when a catheter could not be then passed, so he was readmitted for a day or two, and was taught to pass for himself a No. 7 gum-elastic catheter.

July 19th.—He passes easily a No. 7 gum-elastic catheter every morning before going to work at a stick-mill in his neighbourhood.

CASE II.—Thomas W——, aged sixty, was admitted April 7th, 1886. The patient had gonorrhœa in the year 1855. He was for three months under treatment. He says "it gathered" at the time in three different places in the spongy portion of the urethra. After this he had no other attendance until 1886 when he suffered from retention and œdema of the penis and scrotum, and was admitted as an in-patient of this hospital. He then had catheters passed. For three years, at the least, he has had a fistula in the perineum and one at the inner part of the right thigh, and for two years he has had another fistula by the side of the frænum preputii.

On admission, the last three inches of the spongy portion of the urethra was of a cartilaginous hardness. Urine came only from the three fistulæ, none by the meatus. There was a deep cicatrix involving the lips of the meatus, through which a No. 1 silver catheter could be passed about a quarter of an inch.

April 13th. The patient was placed under ether and a way into the urethra was attempted by the meatus, but a very fine probe only reached about a quarter of an inch. An attempt was then made to get at the urethra by means of the fistulous opening by the side of the frænum preputii, but this failed also. An incision was now made in the central line of the perineum through tissues which cut like cartilages, and after great difficulty the proximal end of the urethra was found, but after half an hour's searching the distal end could not be seen or reached. Mr. Storry then prolonged the incision in the left lateral lithotomy line and entered the bladder. The hæmorrhage was very slight. The patient was then taken back to bed, the urine for four or five days passing by the lateral incision. Several attempts were made to pass a catheter by the meatus, and at last one was passed about four inches.

27th.—The house-surgeon was successful in passing a No. 9 silver catheter, after having introduced several smaller ones through the meatus into the bladder. This was tied in for twenty-four hours, and the following day a No. 4 silver was passed and tied in, but this had to be removed on account of the pain and irritation it caused. For three days no instrument was passed; but on the 4th of May a No. 8 silver was passed pretty easily; a day or two later it was passed again, and the patient himself was instructed to pass a No. 5 gum-elastic for himself. The wound in the perineum by this time was healing rapidly, and no urine flowed by the fistulæ.

June 7th.—The sinus on the inner side of the thigh was laid open and scraped; the incision in the perineum has nearly healed, and the patient passes for himself a No. 6 gum-elastic easily.

21st.—The sore on the inner side of the thigh has healed, the fistula by the side of the frænum also is closed, and there is only occasional slight weeping from the perineal fistula. The patient was discharged to-day, being able to pass for himself easily a No. 7 gum-elastic catheter.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.

CASE OF SPONTANEOUS CURE OF OVARIAN TUMOUR.

(Reported by Mr. C. H. CALLANAN, clinical assistant.)

MARY C——, aged twenty-nine years, was admitted on May 21st, 1886, suffering from ovarian tumour, which caused her great inconvenience, and had been undermining her health for some months past. She had been married two years, but had no family. Three months ago she consulted Dr. Duke, of Steevens's Hospital, for a swelling over the right ovary. It was excessively tender and painful, and gradually increased in size unt it extended over the

abdomen. Steevens's Hospital being closed, she was taken into the Mater Misericordiæ Hospital, and seen by Dr. More Madden, the obstetrical physician, who considered the case one for immediate operation, in consequence of the delicate state to which the woman was reduced in a short period and the intense degree of pain caused by the tumour. A few days after her admission the patient was seen in consultation by Dr. More Madden, Dr. Duke, Mr. P. Hayes, and Dr. Boyd, all of whom agreed that the case was one for ovariotomy, the diagnosis being a thin-walled, globular, well-marked multilocular ovarian tumour. The abdomen then measured 43½ in. in girth. Being close on the menstrual period it was decided not to operate until this should have passed, and it was accordingly postponed until June 15th, tonics being administered to increase the woman's strength. She was up and going about the ward, but on June 9th she took to her bed, complaining of intense abdominal pain. After some hours the pain was followed by incessant diarrhœa and profuse diuresis, which lasted four days. At the expiration of this period the abdomen was found to have considerably decreased and no trace of the tumour was discernible. The patient was again seen in consultation by the before-mentioned gentlemen, including Dr. Byrne. All concurred that spontaneous rupture of the cyst had taken place, with effusion of the ovarian fluid into the peritoneal cavity, its absorption thence, and evacuation by the bowels and kidneys. After this the patient gradually improved. An examination was made on June 16th. Some fluid was still discernible in the peritoneal cavity, but the abdominal pain and soreness were greatly reduced. To relieve the pain and help the absorption, an ointment made up of extract of belladonna and mercurial ointment was rubbed over the abdomen, and a mixture of iodide of potassium given, which she had been taking some time previously. The patient remained in bed about fourteen days, recovering both health and strength. The abdominal swelling had gone down to 29 in. The woman finally left the hospital on July 15th, and was again seen after a week, when she was in excellent health and spirits, being about to take a journey to the country.

ST. JOSEPH'S HOSPITAL, VICTORIA, BRITISH COLUMBIA.

ANEURYSM OF THE INNOMINATE ARTERY; SIMULTANEOUS LIGATURE OF THE COMMON CAROTID AND SUBCLAVIAN ARTERIES; HEMIPLEGIA; DEATH.

(Under the care of Mr. E. A. PRAEGER.)

S. B——, a Frenchman, aged sixty, applied for advice on Jan. 26th, 1885, giving the following account of himself. Family history very good. Has never had any serious illness. Had gonorrhœa years ago, but never had syphilis. Has been a gold miner and has done a great deal of "packing" goods to and from the mines. Two years ago a heavy weight fell on his chest. Shortly afterwards he noticed a swelling on the right side of the chest, between the first and third ribs. The swelling has gradually increased in size. Feels an oppression when he draws a long breath. Has a cough, which has only existed the last month or two, and expectorates a little bright blood occasionally. When he walks fast or goes upstairs, he experiences a feeling which he describes as "like palpitation of the heart, under the swelling." Sometimes when walking in the street he is seized with dizziness and inability to breathe, and has to catch hold of anything at hand to prevent himself from falling. Complains of constant pain at the back of the right shoulder and in the chest, under the swelling. Has a constant numbness in the right arm and hand, and says the pain is so bad that he is unable to sleep at night.

The patient's condition on examination was as follows:—Muscular, but not fat. There is an expansile pulsating tumour extending from the right sterno-clavicular articulation to the second intercostal space. The first and second bones of the sternum and the sternal ends of the corresponding ribs are bulged forwards. A loud rasping bruit is distinctly audible all over the upper part of the right side of the chest. Pulsation in the right radial is hardly perceptible; strong and regular in the left. On pressure being made over the subclavian artery the symptoms are modified. Heart sounds normal. The man was ordered fifteen grains of iodide of potassium three times a day and a low diet. This treatment was continued for some weeks without benefit. At the request of Mr. Praeger the patient was carefully examined by Surgeon-Major Harrison, A.M.D., and Staff-Surgeons T. Canning Hickey and J. Lyon, R.N., who concurred in the diagnosis of aneurysm of the innominate artery.

The man was so anxious that operative measures should be adopted for his relief, although the immense risk attending surgical interference was fully explained to him, that with the consent and valuable assistance of the gentlemen above-named, it was determined to ligature the common carotid below the omo-hyoid and the subclavian in the third part of its course. He was accordingly admitted into hospital, and, on March 26th, chloroform having been administered by Dr. Hickey, an incision parallel with the anterior border of the sterno-mastoid was made through the skin and superficial fascia. The deep fascia having been scratched through with the finger-nail, the artery was reached. At this stage the patient vomited, which caused slight delay, but eventually the aneurysm needle, threaded with strong carbolised gut, was passed from without inwards around the artery, and it having been ascertained that nothing but artery was included, the ligature was applied and pulsation in the temporal artery was found to have stopped. Neither the jugular vein nor the pneumogastric nerve came into view. The wound was sponged with carbolised water and drawn together with silver wire sutures. The patient's shoulder being depressed, an incision was then made in the usual way by drawing down the skin and dividing it on the clavicle. While making this incision the patient vomited, and two small superficial veins (which it was the intention to avoid) were accidentally cut across, and caused great difficulty in securing them. A second incision was then made upwards at right angles to the first, and the deep fascia having been torn through with the finger-nail, the subclavian artery was felt for, and the aneurysm needle, threaded as before, passed around it, and the ligature applied. Pulsation was found to be wanting in the radial artery. The brachial plexus was felt, but the subclavian vein was not seen. The edges of the wound were brought together with silver wire, and the arm having been enveloped in cotton-wool, the patient was removed to bed. Pulsation in the tumour was hardly perceptible. The patient soon rallied from the shock, and complained of pain in the neighbourhood of the operation wounds only. 9 P.M.: Very feeble pulsation was felt in the right radial, none in the temporal, strong and regular on the left side. Temperature in the left axilla normal, in the right 96°. He was perspiring profusely. A subcutaneous injection of a quarter of a grain of morphia was given.

March 27th.—Slept fairly well, but has been vomiting and retching violently. Temperature normal in both axillæ. Pulsation in tumour very much diminished, no bruit. Pulsation in right radial rather stronger than last night; hardly perceptible in the right temporal.

28th.—Temperature normal in both axillæ. Pulse 92. Very much stronger in the left than in the right radial. Not properly established in the right temporal. Pulsation in the tumour hardly perceptible.

29th.—Temperature normal. Pulse 72. Feeble in left radial; more so in right. Has difficulty in swallowing; complains of pain in his head; cannot protrude his tongue properly; his speech is thick and he appears deaf. Pupils contracted.

30th.—During yesterday the left side of the face became paralysed, and during the night the left side became hemiplegic. Temperature normal. Pulse 84, becoming stronger in the right radial, but not so strong as in the left. Still complains of pain in the head. Is quite conscious; converses sensibly, but with thick utterance.

April 1st.—Operation wounds have healed by first intention; hyperæsthesia of left side.

May 3rd. Less hyperæsthesia; passing large quantities (several pints) of urine of low specific gravity (1005); acid, no albumen.

Aug. 10th.—The quantity of urine has steadily diminished under ergot. Complete loss of sensibility and motion in the left side.

Feb. 20th, 1886.—Has continued in much the same state; eats and sleeps well; has recovered sensibility, but not power of movement in the left side.

March 10th.—Caught cold a few days ago; had bronchitis, followed by exhaustion, to which he succumbed to-day—a year, less a few days, from the date of operation.

Remarks by Mr. PRAEGER.—I greatly regret that, owing to a mistake on the [redacted]pital porter, no post-

mortem examination was obtainable. The diagnosis arrived at was that the aneurysm was innominate, possibly subclavio-innominate, but that the aorta was not involved. Judging from the rapidity with which circulation was re-established in the right arm, it is probable that the first part of the subclavian, with the thyroid axis, was abnormally dilated. On several occasions previous to the operation, the patency of the vessels to the brain had been tested by making pressure on the right and left carotids together and singly, and after reading the article, written by Mr. Barwell, on this class of cases, this was considered one suitable for operation. Although the patient subsequently became hemiplegic (probably from failure in re-establishing the cerebral circulation), the symptoms of aneurysm gradually subsided, and there is little doubt that the operation succeeded in prolonging his life.

Reviews and Notices of Books.

An Introduction to General Pathology. By JOHN BLAND SUTTON, F.R.C.S. London: J. and A. Churchill. 1886.

IN this handsome and well-illustrated volume we have not only to welcome the work of a new writer, but, what is equally gratifying, to receive in it an abundance of new facts added to the pathological store. When, at Mr. Hutchinson's suggestion, the Pathological Society of London undertook to investigate more thoroughly than had ever before been attempted the diseases of animals, and had obtained with this object the co-operation of the Zoological Society, the services of Mr. Bland Sutton were secured, and in the main the facts recorded in the work before us have been gathered by him in the course of his five years' steady and unflagging pursuit of the objects which the Pathological Society had in view. The Transactions of that Society have been enriched by many communications from Mr. Sutton; but we venture to think that this further publication, which embraces so considerable a range, will astonish even the members of the Society, who have already been witnesses of the thoroughness and zeal with which he has pursued his researches. The gist of the contents of the volume was given by the author in his Erasmus Wilson Lectures at the College of Surgeons last spring; but it is needless to say that the topics there treated have received fresh illustration and considerable expansion here. The work is divided into five sections: the first, dealing with aberrations of nutrition, illustrates the subjects of hypertrophy and atrophy, correlation and degeneration; the second treats of inflammation and its results; the third is devoted to the cystomata; the fourth to neoplasms; and the concluding section reviews the subject of evolution as influenced by pathological processes. To adequately treat of such subjects in respect to the animal world, the writer must be as much a naturalist as a pathologist, and undoubtedly the present author presents just this combination. Such chapters as those on correlation and on the cystomata exemplify this, whilst the predominant idea of the work is the explanation of pathological facts by means of the evolution hypothesis.

Although for the most part the work consists of an aggregation of original observations upon facts of pathological interest in the animal world, there are not wanting pages in which the author shows that he possesses to a marked extent that great gift of generalisation which is so essential in the collation and comparison of individual facts. Perhaps the best instance of this is to be found in the chapter upon Inflammation, where Mr. Sutton boldly assigns a *rôle* to the ubiquitous leucocyte which far outstrips the conception of Cohnheim. For whereas that much-lamented observer and acute thinker was content to attribute the phenomena of inflammation mainly to deterioration of the delicate tissue of the vessel wall, Mr. Sutton, by a skilful use of the most recent discoveries of intercellular digestion and the phenomena of tissue-resorption as observed in the metamorphosis of the amphibian, sees in the white blood-corpuscle an active (we might almost say a combative) body which is stimulated to increase and multiply for the purpose of resenting injury and preventing the intrusion of foreign matter into the living organism. The conception is one which dazzles as much from its simplicity as from the ideas to which it gives rise, opening up suggestions in the direction of explaining the nature of so-called specific inflammatory neoplasms, and capable even of extension into the wider field of all new formations. Great as has been the dignity of the leucocyte hitherto—indeed, its amœba-like characters long since fascinated some naturalists, who endowed it with a special individuality,—it has certainly never been assigned so wonderful a *rôle* as Mr. Sutton would fain have us admit it to possess. We may nevertheless commend the study of this chapter as one full of suggestiveness to those who desire to extend our notions of pathological processes a little beyond their mostly too confined limits.

The chapters devoted to the Cystomata are full of interesting facts well marshaled. They go far to fill up a distinct lacuna in our knowledge. Indeed, the subject has never been adequately treated hitherto in any English text-book; for Virchow's classical description in his great (but unfinished) work on Tumours is not available to the English-reading student. Again, thanks to many observers, and largely to the author of this book, very material additions have been made to the subject, especially as concerns cysts in connexion with the reproductive organs; so that we venture to think that subsequent writers will be under great obligation to him for what he has done in this direction.

As to the chapters on Neoplasms, it must suffice here to say that Mr. Sutton is an ardent adherent to Cohnheim's doctrine of "tumour-germs," and that he adduces very numerous instances of various kinds of new growth in all varieties of animals which bear largely on that doctrine. Especially to be mentioned are the examples of teratomata, where, again, we find many new paths opened up, and advantage taken of the knowledge afforded by embryological research. Indeed, the book is one which will well repay careful study; and the fact that it is the product of one of our younger pathologists is encouraging, not only because it is written in the true scientific spirit, but because it is of good augury for many future contributions from the same source.

Il Clima di Roma. Conferenze fatte nella Primavera del 1885, inaugurando l'Istituto d'Igiene Sperimentale della R. Università di Roma. Con una Carta Topografica e Geologica dell' Agro Romano, e cinque Tavole illustrative. Per CORRADO TOMMASI-CRUDELI. (*The Climate of Rome.* Lectures delivered in the Spring of 1885, at the opening of the Institute of Experimental Hygiene in the Roman University. With a Topographical and Geological Map of the Agro Romano, and five illustrative Plates. By Dr. CONRAD TOMMASI-CRUDELI.) Rome: Hermann Loescher and Co. 1886.

MEDICAL climatology has made advances of which the importance could not be better appreciated than by comparing the present work with that published on the same subject by Sir James Clark half a century ago. Dr. Tommasi-Crudeli comes to his task equipped with accomplishments which were hardly considered as within the medical province in his distinguished predecessor's time. Himself an original authority in physiology and pathology, he possesses a knowledge of the earth's crust, its flora and its fauna, the waters that permeate it, the winds that sweep it, such as more than fulfil the Hippocratic ideal. So qualified, he has made a special study of the climate of Rome, and the results of his successive monographs on the subject are revised and condensed in the present volume.

When we talk of the Roman climate we cannot dissociate the theme from its distinctive characteristic—the malarial

poison. What is this poison? Till the researches of Tommasi-Crudeli and Klebs, published in 1879, the most plausible answer was that of Dr. Léon Colin, who defined it as an "intoxication tellurique," an earth-poison generated by the surplus vegetative energy of an abnormally fertile soil, whose fecundity was very partially absorbed by the scanty sprinkling of herbage that overspread its surface. Cultivate this soil, render to this vegetative energy its appropriate pabulum, and you provide the antidote to malaria. Such, stated with extreme brevity, was the theory of Léon Colin, embodied in a work of great ability, which, appearing as it did at the outbreak of the Franco-German war, encountered a public too preoccupied to give it the study it deserved. Tommasi-Crudeli combats this theory. He denies that the Roman Campagna possesses anything like the exuberant fecundity with which it has been credited. Its really fertile tracts are few and far between, rarely compensating the agriculturist for his labour as, indeed, was well known to ancient husbandmen. Then, again, if the poison were gaseous, as Léon Colin's theory implies, the malaria-surcharged atmosphere ought to be at its maximum at noon-day, when the exhalation from the soil is greatest; but, on the contrary, the localities in which malaria is most pronounced reach their maximum of danger in the morning and evening—those periods of the day when the difference of temperature between earth and atmosphere renders the ascending aerial currents most powerful and most apt to transport the material of the poison. That material, according to Tommasi-Crudeli, is a living ferment, encountered equally on the mountain and the plain, in dry soils and in humid. Its existence was suspected and unscientifically described as long ago as the decline of the Roman Republic by the agriculturist Varro, and its nature and form are defined by Tommasi-Crudeli as a "Schizomêtès bacillaris." For its development it requires a temperature not lower than 20°C. (a moderate degree of humidity) and the immediate contact of the atmosphere with the soil it infects. As the absence of a single one of these conditions prevents the development of the malaria, so certain localities exhibit at times a natural suspension of the poison. In winter, for example, the fall of temperature below the required 20° causes a thermic suspension; the loss of the necessary humidity under prolonged drought causes a hydraulic suspension; and the interposition of sheets of water or of a thick matting of turf on the laying down of a pavement, by preventing the immediate contact of the atmosphere with the infected soil, produces an atmospheric suspension of the malaria. All this argument is worked out with great clearness and force of style in the fourth and fifth lectures, which may be recommended to the teacher or lecturer as models of what academic exposition ought to be.

The various modes of clearing the Roman climate of malaria are examined in much detail, and cannot but interest the practical hygienist who has to deal with similar problems elsewhere. One striking demonstration, in which Tommasi-Crudeli's proficiency as a classical scholar and archæologist comes into play, is that of the immunity from malaria enjoyed by Rome, under the *régime* of the Antonines, whose system of cuniculur drainage, whereby the hydraulic suspension of the poison was attempted, was at once ingenious, laborious, and—but for its premature discontinuance—efficacious. Beautifully executed illustrations of the process supplement the author's exposition, and are the next best thing to a personal visit to the spots where excavation has brought the works to light. Other specimens of his power of evoking and rewarding attention are his criticism of Lancisi's doctrine of the causal relation of stagnant water to malaria—the "palustral prejudice," as he calls it,—and his exposure of the same eminent physician's fallacies on the influence of forest-planting as a protection from the poison in its alleged transport by the wind. But on these subjects we have already, in other departments of the journal, summarised the author's conclusions, and we refer to them now as having received his latest touches in answer to the animadversions of recent critics. Notwithstanding its localised theme, the book leaves no vital phase of meteorology untouched, so that its publication in an English dress would be a genuine boon to the profession at home and in the colonies. Messrs. Loescher, we may add, have done their part most creditably. The excellence of the plates and of the maps, particularly the fully-detailed and finely-coloured geological and topographical chart of the Agro Romano, are quite in keeping with the almost sumptuous finish of the paper and typography.

Chemistry of the Carbon Compounds; or, Organic Chemistry. By Professor VICTOR VON RICHTER, University of Breslau. Authorised Translation from the Fourth German Edition, by EDGAR F. SMITH, Professor of Chemistry, Wittenberg College, Springfield, Ohio. London: Henry Kimpton. 1886.

LET us begin by admitting that Professor Smith has done good work in translating Professor Richter's well-known text-book. It was wanted, for, alas, German is still an unknown tongue to many, and we have no English equivalent to Richter. The translation, and we may add the printing, of the American edition are excellent, and any faults we may find are personal to the German author. Fault-finding, however, is not our primary duty here. Organic chemistry is now such a huge growth that no ordinary text-book can adequately represent it. Of late real knowledge has been gained of the constitution of carbon compounds, and the rapid growth of the so-called organic chemistry has been mainly due to this study, and to the development of a symbolic notation by which its results are expressed, and indeed constantly anticipated. A structural formula is at once an explanation and a prophecy, for when once we know the structure of a compound, its synthesis generally follows as a matter of course. The artificial production of alizarin is a case in point. If we knew the structural formula for morphine we should probably be able to prepare it without the assistance of the poppy. Now, Professor Richter's book of over 700 pages, much of it printed in small type, is mainly devoted to classification and structure. An immense number of compounds are included, and the most modern views of their constitution are stated. The book covers the whole range of organic chemistry, and we have only to look it over to realise the enormous extent of the science. Short descriptions generally very short, and even meagre—are given of each compound, and the general effect of the whole is that of a *catalogue raisonné*, rather than of a manual for practical use. The book is extremely valuable as an adjunct to others, but alone it would be useless to anyone. Of experimental detail there is very little indeed, and condensation is carried so far that in some cases it would be hardly possible even for a trained chemist to carry out the operations alluded to in the text. Nevertheless, every chemist will use it, and will only regret that it was not twice as large as it is. We are glad to see that the trimethylene and tetramethylene groups, so important as intermediaries between the paraffins and the benzene series, receive fair recognition.

THE FEMALE MEDICAL AID ASSOCIATION.—At Simla, on Sept. 29th, a meeting of the above Society was held, under the presidency of Lady Dufferin. An account was given of the useful work done by the Association, and an appeal made for funds to warrant a widening of the scope of its operations, in honour especially of the Queen's jubilee next year.

Abstracts
OF
INTRODUCTORY LECTURES
DELIVERED AT
MEDICAL SCHOOLS OF LONDON AND THE PROVINCES
AT THE
Opening of the Session 1886-87.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. WADHAM,
SENIOR PHYSICIAN TO THE HOSPITAL, AND DEAN OF THE MEDICAL SCHOOL.

AFTER welcoming his audience, and especially the new students, Dr. Wadham described the additions and improvements which had been made in the school premises, the increased facilities which had been provided for the study of physiology, and the appointment of Dr. Delépine as special physiologist. Those who knew him, and had already worked under his supervision, would, he said, recognise in his name a guarantee as to the efficiency with which this subject would now be taught, and would find that, for practical work and teaching purposes, the physiological laboratories of the school would be as complete as the most exacting students could require. He then alluded to the competition which was taking place between the medical schools of London and the system of offering entrance scholarships, saying that bold advertisements and offers of pecuniary advantages were superseding the attractions which formerly hung like a halo round the names of men of reputation and experience, and that the old feeling which made a man regard his school as his *alma mater* was threatened with extinction; that students were being bribed to enter the schools; and that there seemed to be a growing tendency to make medical education, like medical advice had long become, a gratuitous gift to all who sought it. He warned the students that the medical profession was comprehensive and difficult beyond most others, that it required for its study more than average abilities and energy, and that, in order even to master the scientific portion of it, they would have to make use of their brain as well as their memories. In advising them as to their conduct, he said: "Remember the oft-repeated boast of Mephistopheles, 'how little beyond devilish opportunity is needed to make men sin,' and keep out of the way of temptation. Above all, neither forget nor be ashamed of the religious and moral principles in which you have been reared; these are the connecting and preserving bonds of civil society, the source of all good and much happiness, and our best comforters in those days from which no man can expect wholly to escape, when the clouds obscure the sun, and all seems dark and desolate before him. You will require them also as safeguards against the temptation to idleness, and perhaps worse, by which, in common with all young men living in large towns, you will find yourselves constantly surrounded dangers against which neither the care nor the advice of others can shield you, and which can only be avoided by the possession of those good principles which, I trust, have been bred in your bone and burnt into your blood as the richest heritage your parents could give you."

In referring to the difficulty students experience in passing their numerous examinations in the four years supposed to be sufficient for that purpose, the lecturer said, "As a rule, I should say that this is only done by students of exceptionally good abilities and memories, and only by such of them as have the good fortune not to fail in any of their examinations. It would, I think, be better to recognise this fact and extend the period of study for at least another year. This would be fairer to parents, who are now systematically deceived as to the length of time their sons have to remain at the schools, and would be a decided relief and advantage to the latter. The authors of the conjoint scheme appear to have some inkling of this, for they invite students to present themselves for examination in several subjects immediately after registration [illegible] Solly. Le Gros [illegible]rds, they invite, but do not compel, them, before entering the medical schools, to study chemistry and physics, and pharmacy and materia medica, in the latter case putting the horse behind the cart, and asking students, before they know anything of disease, to come and be examined as to their knowledge of the medicinal action of the agents used for its relief. The effect of this regulation is either that students are crammed in these subjects beforehand, or else have to commence their studies with an amount of work which they ought to get through in their first year, and which they can only accomplish by a process closely allied to cramming here. In this manner they learn an innumerable number of facts, but have no time to assimilate or coördinate them. They acquire information, but not knowledge, not even the knowledge of how to put this information to practical account. This information they deliver over to their examiners as much as possible in the very words in which they received it from their teachers, and, unless gifted with very good memories, forget it immediately. To borrow a very old illustration, it is as if sheep were to vomit up the very grass itself which they have cropped and swallowed, to show how much they had eaten, instead of concocting it into wool and milk. The regulation is also unfair to the schools, for it obliges them to maintain a staff of teachers upon subjects which students are allowed, if not encouraged, to study elsewhere. Unless a student by the end of his first year is successful in passing his examination in all these subjects, with the addition of elementary anatomy and physiology, he has either to sacrifice his next winter session in getting them up, or else to study higher anatomy and physiology, and to dissect, at a time when his mind is busy with some or all of these subjects. In either case the result is that he falls behind with his work, and probably takes nearer six than four years to obtain his qualification to practise. It is true that an attempt has been made to bring the examinations within the capacity of students by issuing synopses as to the range of most of the subjects, and allowing them to take them up one at a time. The privilege has also been lately granted of allowing students to postpone until the second stage of their examination the subjects of pharmacy and materia medica. By this arrangement the student, even without being once rejected, has to appear nine times before his examiners in order to obtain the double qualification under the conjoint scheme. These synopses, however, are either so obscurely worded as to render their meaning difficult, or else some of them are of such a nature as to be only imperfect guides to students, and can hardly be said to bind the examiners at all. For instance, in the case of the synopsis relating to elementary physiology, we find that although the varieties of connective tissue which have to be learnt are fully marked, yet those of epithelial, muscular, and ner[illegible] tissues are not mentioned. The teacher is there obliged to demonstrate all the varieties of these in order to cover the whole ground. This brings us to the fact that at the end of his first year a student is supposed to know all the elementary tissues of the body and their varieties, with the exception of a few varieties of connective tissue. It seems, also, an anomaly to tell the unfortunate first-year student—as he is told in the synopsis—that the anatomical knowledge required of him is merely an acquaintance with the bones and the attachment of the muscles to the bones of the upper and lower extremities, and at the same examination to ask him to enumerate the principal changes which the food undergoes in the mouth, the stomach, and intestines, to explain, in fact, the function of organs with which he is anatomically unacquainted—a subject about which he can know nothing except as an effort of memory. This, I suppose, is the necessary consequence of dividing into two parts the examination in that which is really one science—a proceeding no more reasonable than it would be to divide astronomy into two sciences, one teaching the figure and size of the heavenly bodies and the other their movements.

"If I have detained you so long with all these details, it is because I consider that some reform is needed in the present system of examinations, and that the studies of the first-year student should be made less burdensome. These synopses should also be made clearer and more definite, should indicate all the questions that can possibly be asked, and, in addition to being a guide to the student and teacher, should be binding on the examiners. I believe, however, that the best reform would consist in an extension of the period of study; and in obliging the student to pass an

examination in such subjects as chemistry and physics, and pharmacy and materia medica, excluding therapeutics, before he enters a medical school, or, at least, before he commences the study of human anatomy and physiology. If animal and vegetable biology were substituted for pharmacy and materia medica, which latter concern the chemist more than the physician, and therapeutics were included in the examination in medicine, it would, I believe, be a better arrangement, an improvement in the student's education, and facilitate his subsequent studies. I also think that the examinations in elementary anatomy and physiology might with advantage be abandoned. These repeated examinations worry the student and interrupt his work, and are merely tests of his progress which might be much better carried out by the school authorities. Should the conjoint board ever take this view of the subject, they would find the materials for teaching ready to their hand at the London University, in the arrangements of some of the larger schools, and in that which we, in common with some of the smaller schools, have made with the Normal School of Science at Kensington. In this manner students would have time and facilities for studying and understanding subjects which they now only get up by memory for examination, and a check would be put to the pernicious system of cramming, without which no ordinary student can now get through his examinations in the time allotted to that purpose. The period of study being thus prolonged, the expense of medical education would be apparently increased. This increase, however, would be more apparent than real, for the intelligent student from choice and the dull one from necessity invariably occupy more than the conventional four years in acquiring even the rudiments of their profession."

In speaking on the subject of the discipline of medical students, and the proposal to attach colleges to each of the medical schools, the lecturer said: "I believe that in the treatment of the subject the public have not used the wisest method of arriving at a just conclusion. They have placed theory before experience, and the visionary before the practical, and in forming their opinion have been influenced more by their feelings and sentiments than by their reason and judgment. Many, too, who have written on the subject have evidently had no intercourse with students, and are ignorant of their disposition and feelings. At present I have neither read nor heard any argument in its favour which my own knowledge and experience do not enable me to refute. Few men have seen more of students than I have. I have known them living under the roofs and protection of their parents; in small parties under the care and supervision of gentlemen of upright character and having a full sense of their responsibilities towards them and towards their parents; and I have known them living in lodgings free from all control. I can honestly say that the last of these students were as a rule quite as good as the first, and that my experience of the result of associating students together has been anything but encouraging to an extension of that system. So far as my experience goes this tends far more to idleness and gossiping and card-playing than to habits of industry and study; and not unfrequently in these small coteries the evil influence is stronger than the good. Some of those who have proposed the foundation of these establishments have probably done so from an amiable desire to secure for the medical student the advantages of the collegiate system as it exists at the two Universities, and probably in ignorance of its many drawbacks even there. They have, however, overlooked the fact that these colleges exist as the result of past liberality and benevolence, and that the authorities by whom they are managed are supported by funds derived from the same source. Here they would have to be built and managed upon such conditions as would make them successful mercantile enterprises, and this I hold to be impossible except at an expense to students greater than their parents would be prepared to pay. The fact is also ignored that the most important factor in the success of the University system is, not that the students themselves are much controlled, but that the authorities possess the power of controlling and suppressing throughout a considerable district many of the temptations to idleness and dissipation and vice which exist, unchecked and uncontrollable, in this metropolis. What advantage would there be in 'gating a student in this town at ten or nine, or even eight in the evening? Long before that hour, if so disposed, he would find time and opportunities to commit all the sins in the Decalogue, and a good many indiscretions outside it. The success and character of a student depend much more upon his early training than upon any other circumstance. If his parents have brought him up to be industrious, in the principles of virtue and honour, and with a love of truth, he will succeed and prosper in whatever situation he is placed, and the earlier he is encouraged in habits of self-reliance and independence the better he will be fitted to withstand the temptations and accept the responsibilities inherent to his profession. If, on the other hand, his parents have failed in their early duties towards him, no amount of supervision or discipline to which he can be submitted here will compensate for their neglect. They will reap as they have sown, and he will go to the bad under whatever system he is placed. Much of this outbreak of anxiety for the welfare of medical students is due to a still-existing delusion that the morals and conduct of medical students are worse than those of other young men. On this subject I will read you a passage from an address given to the students of this hospital thirty-six years ago by Sir Benjamin Brodie. After advising the students as to their conduct he said: 'Gentlemen, I offer you this advice, not because you are medical students, but because you are young men. I do not believe that you are more in need of such admonition than others of the same age. I know not what medical students may be at other schools, but as to those belonging to this school, with which I have been so long and so intimately connected, I feel it but just that I should express my sincere conviction that there was always as large a proportion of young men diligent in the pursuit of knowledge and decorous in their general conduct as is to be met with in any class of society.' That which Brodie said so many years ago I can now repeat; for if in these times of constant change we are in danger of losing some of our traditions, we still hold fast to that which is comprised in the motto, so brief and yet so comprehensive 'Manners make the man.' It is probable that, as the outcome of this discussion residences of some description capable of accommodating a few of the first-year's students will be established in connexion with some of the schools. Such an establishment would doubtless serve as an attractive advertisement and be a kind of harbour of refuge into which a parent might steer and anchor a troublesome youth, in the hope of finding for him there a more skilful pilot than he himself had proved. But that such establishments will ever be popular with students or have a beneficial influence on their moral training, or on their medical studies, I, for reasons already stated, have no belief. It is with students as with every living product of creation a case of the survival of the fittest; and in the inevitable contest many of them will disappear.

My task is finished. I have spoken to you of subjects having only a passing interest. I might have addressed you from a higher standpoint, and told you of the endless potentialities of the science and art you are here to study the science of life, the art by which that life is prolonged and preserved; that science has many problems to be solved and many secrets to be revealed; that art is yet in its infancy, and has many triumphs and rewards for those who shall carry it forward on its conquering course. They who have wrested the secrets of creation from the antediluvian rocks, or subdued the forces of the elements around us to the purposes of man, did not rest content with text-books or the words of the teacher. They went to them only to learn to read. They studied their real tasks with unceasing industry in the book of nature herself. Is less required from th se who would read the mysteries of life? You learn here the alphabet and the primer. If you would go further and learn those deeper lessons which enable you to grapple with the enemies of life, with pain, disease, and death, you must read with your own eyes, you must reason with your own brains, you must feel with your own hearts, and your lives must be devoted to the profession into whose ranks you have this day entered as students."

KING'S COLLEGE

INTRODUCTORY LECTURE BY DR. GEORGE JOHNSON, F.R.S., EMERITUS PROFESSOR OF CLINICAL MEDICINE AT THE COLLEGE.

DR. JOHNSON began by referring to the death of Mr. H. Royes Bell, one of the most esteemed members of the surgical staff of the hospital, who, not long since, was suddenly called away, to the great grief of all who knew him. Then with reference to the three great subjects of anatomy, physiology, and chemistry, to which the student's attention has first to be directed, he said it need not be

insisted on that a knowledge of the structure and functions of the human body is an essential foundation for the practice of medicine and surgery. It may not appear so obvious, but it is not less true, that some knowledge of chemistry is absolutely necessary for every practitioner. In addition to its great practical utility, a diligent study of the facts and laws of chemistry will prove an invaluable means of mental training and discipline. Observation, memory, and the reasoning faculty are all exercised and strengthened by a thorough study of that delightful science. Referring next to the various classes of physicians, surgeons, general practitioners and specialists, the lecturer maintained that the only safe foundation for specialism is a thorough knowledge of disease in general, and he illustrated this by reference to diseases of the eye and the larynx. There are, he said, few, if any, special departments of practice which have so indisputable a *raison d'être* as ophthalmic surgery; but there are few diseases which afford so many and such striking illustrations of the close relationship between various tissues and organs and the dependence of apparently local structural changes upon remote, and often general, constitutional states as those which affect the eye. Thus, in one case, impaired vision may be seen to be caused by degeneration of the retina, the result of Bright's disease of the kidney; in another, blindness may result from mechanical obstruction of a retinal artery by a small blood-clot detached from a diseased valve of the heart; while in yet another, loss of sight may be due to degeneration of the nerve of vision, consequent on the growth of a tumour in the brain. Thus, an oculist unacquainted with diseases of the kidney and heart and brain would often fail to correctly interpret the ocular defects with which he had to deal; while on the other hand, a physician who undertakes the treatment of renal, or cardiac, or cerebral disease, without having acquired the power of inspecting the interior of the eye with the ophthalmoscope, is at manifest disadvantage. Again, the laryngoscope has shown that while in one case loss or impairment of voice may be due to some disease within the larynx, in another, it may be caused by an aneurysm or other tumour in the neck or within the chest pressing on a nerve which supplies the organ of voice; while, in yet another case, the laryngeal trouble is traceable to disease within the brain or spinal cord. A mere laryngoscopist then, whose vision is limited to the larynx, would be incompetent to deal successfully with the diseases of that organ. These and other like facts show that between the various organs and functions of the body there exists, both in health and in disease, a correlation, the recognition of which is of the highest practical importance. The universe is governed by all pervading immutable laws. As the astronomers, relying upon the laws of gravitation and of planetary motion, have discovered a previously unknown planet by observing the disturbed orbit of one previously known; as the biologist, in reliance upon the invariability of organic types, has been enabled from the fragment of a skeleton, or from a tooth, to reconstruct the framework of an extinct reptile or bird or mammal; so the pathologist and the practising physician, relying upon the laws of physiology, which, although modified, are not suspended by disease, have learnt that a disease commencing in one organ may involve widespread structural changes in many other parts. It is obvious, then, that the body cannot be separated into different parts so as to make one of them the exclusive object of study and practice. The lecturer entered a protest against the rapid multiplication of small special hospitals, which are injurious by diverting funds from the general hospitals, of which most of them are sorely in need, and by attracting special classes of patients which in the hospitals connected with medical schools would be utilised for the practical instruction of their students. Reference was made to the value of the various modern aids in the diagnosis of disease, such as the ophthalmoscope and the laryngoscope, and the importance of a correct interpretation of symptoms. A most important duty of the practitioner is to ascertain what in the habits or the surroundings of the patient is the cause of disease, and the frequent and powerful operation of mental influences was next adverted to. Referring to the disobedience of the law with regard to vaccination by a large proportion of the inhabitants of Leicester, Dr. Johnson said, "It is as certain as that the sun will rise to-morrow that at no distant period small-pox will invade the town of Leicester, and as a result there will be such a massacre of the innocents—innocent victims of parental ignorance and prejudice—as will probably carry conviction to Sir Solly Le Gros—or of the House of Commons who lately had the assurance to ask for an inquiry into the practice of vaccination." Briefly referring to the question of medical ethics, the lecturer said that few special rules would be required if all could act upon the comprehensive maxim, "Thou shalt love thy neighbour as thyself." He warned his hearers against the error of supposing that their studies were at an end when they have obtained their legal qualification to practise. The conscientious practitioner must be a diligent student to the end of his days. The man who is too old to learn is too old to practise. "That which Lord Bacon has eloquently said of all knowledge is in an especial manner and degree applicable to the knowledge which it will be the chief business of your lives to acquire and to use for the benefit of mankind—'It is not a couch whereupon to rest a searching and restless spirit, or a terrace for a wandering and variable mind to walk up and down with a fair prospect, or a tower of state for a proud mind to raise itself upon, or a fort or commanding ground for strife and contention, or a shop for profit or sale, but a rich storehouse for the glory of the Creator and the relief of man's estate.'"

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY CECIL YATES BISS, M.A., M.D. CANTAB., M.R.C.P.,

ASSISTANT-PHYSICIAN TO THE MIDDLESEX HOSPITAL, AND THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE lecturer commenced by remarking on the object to be kept in view by one giving an introductory address, and then proceeded to offer a hearty welcome to the students present for the first time, and with whose aspirations, desires, and perhaps misgivings in view of the apparent difficulties before them, he strongly sympathised. "Let me," he said, "greet you as pupils and as fellow-students. Our office is to assist you to decipher the characters, written often legibly, often most illegibly, upon the leaves of that great volume of disease that this hospital constitutes; and as fellow-students we invite you to take your stand with us in its wards that we may study together the ever-new and ever-varying phenomena of disease, all sharing alike the conviction that the moment the consciousness of knowledge received shuts the eye to the access of more, the moment that the baneful idea of finality in such learning infects the mind, and we conclude that there is no more light or truth to break forth than that which we have perceived, that moment does the man who has finished his learning become unfit to be, in any worthy sense, the instructor of others. For in clinical teaching, as in all other training worthy of the name of education, according to the true meaning of that word, the office of the teacher is (perhaps here more than anywhere) so to influence the m of the pupil as to evoke and train his undeveloped pov for the independent observation and induction of the studied facts."

Having spoken of the increased strength imparted to the school by the addition to the teaching staff of Mr. Sutton and Mr. Hern, the lecturer referred to the advantage that would be derived by the students in the proposed residential college—"a building commodious and handsome, occupying the site of those adjoining edifices in whose windows many of you have had the opportunity, during your brief intervals of leisure, of studying domestic life in its apparel, utensils, and casual incidents." In congratulating the new comers on the choice of the medical profession, Dr. Biss said: "The ruthlessness of examining boards within, and the steady pressure of public opinion from without our borders, are forces that are steadily lifting the profession to a higher level of knowledge and skill, coupled with a greater delicacy of thought and work. And a force as strong as either of these is the improved tone of feeling within the profession itself as to the responsibility of its functions and the esteem they merit at the hands of society. The doctor was once expected to ring the servant's bell—in country houses, at least; nowadays, I fancy, the squire and the doctor would both feel equally ashamed to meet on such terms. Little wonder that it should have been so, when the art of healing was regarded as a mere craft rather than as an intellectual and scientific calling, demanding a mind expanded by education, trained to feel and decide for its patients in the direst emergencies of anxiety, pain, and danger. The barber, the leech, the apothecary, the surgeon of ancient days, a man dismal with bones and blood, formed an ascending series,

from which we now see evolved modern physicians and surgeons whose claim to a scientific recognition and a social standing equal to that of any other calling is, happily, justified by facts and, for the most part, admitted at the hands of society. Yet not altogether so: there is not yet that ability that there should be, even amongst educated people, to differentiate the physician from the quack and the surgeon from the bone-setter, and to discern that the advertising pretender or practitioner probably takes the course of displaying his merits to the world, not so much from fear that he might otherwise be unknown, as that if left to the prior recognition of more competent judges it might be decided that there was nothing worth publishing. Nor is the social recognition of our members yet all it should be, though, as to our rank and file, it is a simple statement of fact to say that the medical students and practitioners of modern times are, in point of general culture, knowledge, manners, and gentlemanly feeling, quite abreast of their fellows, who are aiming to fill, or who stand in, the ranks of the Army, Navy, Bar, and Church, while I venture to think that in point of earnestness for work, devotedness, and self-denial in it, they are second to none, and perhaps ahead of all." The lecturer then entered upon a survey of the path of study, and pointed out certain facts, which might, in the absence of personal experience, help his hearers to save time, concentrate their energies, methodise their work, and avoid the pitfalls into which many a student falls. He counselled them to practise from the first day of their course the thrift of time. The curriculum being limited to a minimum of four years, the division of the course of study had been framed so as to meet, stage by stage, the arrangements of the conjoint scheme of the Colleges of Physicians and Surgeons. It followed that no student had any time to lose. It was impossible for him who dawdled through his first year to make up satisfactorily for it in his second. When the second year came it would bring with it its own tale of work, and it was a real misfortune when a man found out too late the disadvantages of dislocating his work from its due relation to the curriculum, and had to grind away at revising for the anatomy and physiology examinations when he ought to have his mind at leisure for the clerkship or dresserships he had come to hold.

The lecturer went on to say that in medical study there was a special faculty that must be trained—namely, the faculty of close, shrewd, thoughtful observation, and the power of correct, inductive reasoning upon the phenomena observed, connecting effects with causes, and drawing true inferences. But that upon which he would ask his hearers to lay supreme emphasis was that in medical studies there was absolutely nothing that could supply the place of the observing faculty. With it all else might follow; without it a man could no more make a truly able physician and surgeon than an ordinary mortal could write Byron's poetry, fashion the sculpture of Praxiteles, or compose the immortal strains of Handel. Jenner observed, what indeed many had observed before, that cow-pox was communicable to man; but it was not till he had patiently carried out the toil of observation and induction for a very long time, and ascertained that it was only in a particular condition of the cow-pox pustule that the virus was capable of efficiently protecting the human constitution, that the magnificent discovery of vaccination was attained. "The noble words of Harvey, spoken two hundred years before, seems almost prophetic of his success: 'Nature herself is to be addressed; the paths she shows us are to be boldly trodden; for thus, and whilst we consult our proper senses, from inferior advancing to superior levels, shall we penetrate at length into the heart of her mystery.' ..... The demonstrative is the most interesting as well as effective method of instruction. Tell a child that heat expands mercury, and such-like facts, he yawns, or thinks of his marbles. Show him a thermometer, let him hold its bulb in warm water and see the index rise, and he is all interest; probably never will forget the fact; and, better still, will shortly apply the observing faculty, thus trained, to the attempted elucidation of something else. This is what makes medical study so charming: the method of demonstration pervades it. If your work is carried on on these lines, your progress will be sound, and you will really be trained, not for examinations merely, but for the more difficult work beyond. But if you substitute books for facts and words for things, you will find yourself in the end far wide of the mark, not having (as has been said) 'at the back of your mind, the change for words in definite images which can only be acquired through the operation of your observing faculties on the phenomena of nature.' I remember hearing one of my old teachers say—and it made a great impression on me—that the most clever clinical note he ever remembered to have heard read to him in the wards by a clinical clerk was found on examination of the patient to be incorrect—pure romance, not fact! Train your senses, then, by observing facts above everything, and you will be as much surprised at how little you can at first see, feel, and hear with certainty in handling cases of disease, as you will afterwards be at how much you can make out with perfect certainty when your training is advanced. ..... Let me venture to advise you to acquire your knowledge of anatomy from the structures themselves more than from books, though books, in their proper place, may not be neglected. Anatomy, however, can never be interesting if it be viewed as the aggregation of detailed facts. It is the grouping of those facts by relations of structure and function, and the generalisations that may be built upon such associations, that cause the subject to teem with interest and facilitate its comprehension. To notice such facts as that all the muscles which have for their function the expression of emotion are supplied by the facial nerve (though some of them in man are ordinarily insignificant and inert, such as the occipito-frontalis or the muscles attached to the auricle, yet in many animals largely subserving that function); or that, as was pointed out by the late Mr. Hilton, the same nerve that supplies a muscle or joint supplies the skin over the insertion of that muscle, or over that joint; or, again, that the nerves which supply muscles enter them at the points where they are the most secure from pressure, well illustrated by the curious fact that the phrenic nerves (literally 'the threads on which our lives hang') pierce the diaphragm, to be distributed upon its *under* surface, where gravitation tends to relieve them of the pressure of adjacent organs,—to note all this not only removes tedium from the work, but greatly assists the burdened memory by classifying in a natural manner the facts it has to carry to the examination table." Having warned his hearers against the danger of depending upon "tips" and "rhymes," the lecturer spoke of the place occupied by Physiology in medical studies. "Let me beg of you," he said, "to form a right conception of what that place is. Physiology is the science of *function*: it does not mean cutting and mounting sections or analysing fluids, important as these things are; that is but anatomy still, the minute anatomy of the tissue, or, if I may say so, of the fluid. It is when you ask, 'What does this muscle do?' 'What does that nerve connected with it do when contraction happens?' 'What is the chemistry of these changes?' 'What their relation to other vital processes?' and questions like to these, that you are studying true physiology. Much as our teaching has improved in this particular, it seems to me that there is room for improvement still. The precious hours of the physiology student are so much swallowed up by section cutting and staining (often so fascinating a thief of time) that the problems of pure physiology are but too little considered with that detailed reflection that they should be when it is remembered that so much of our future work in the treatment of disease depends upon the application of such knowledge. For let us never forget that there are many diseases that, in the anatomical sense, have no pathology. Epilepsy, migraine, diabetes, asthma, and not a few others, wait their complete elucidation at the gates of the medical physiologist. Grateful as I feel for the immense advances of physiology in recent years, and for the enormous advantages to medicine that the labours of such men as Michael Foster and Burdon Sanderson have conferred, I would with all deference venture to record the conviction that, advantageous though it be for some reasons, to study pure physiology—that is, physiology apart from its pathological bearings,—the day must come when the relations of pathological to normal function shall be more habitually studied together, and a fresher development of the science be reached, which, if less "pure" in its ideal, shall be much more complete in its scope, and much more useful to mankind ..... The examinations in anatomy and physiology over, the way is clear to clinical medicine and surgery for a space of two years. This is the period of supreme interest, as of supreme importance; utilise [redacted] it. And that you may do so, allow me [redacted] uscels. Do not be

satisfied with the cases allotted to you, but study every case in your wards, and keep in your own case-book a concise record of each. Make a point of seeing every case, examining it (if there is no reason to the contrary), and forming at least a provisional diagnosis for yourself before the physician's or surgeon's visit, and, if possible, independently of the resident.....Remember, too, that it is the out-patient department, rather than the wards, that supplies you with the class of cases of the slighter disorders and accidents, as also of those functional, subacute, and chronic diseases that will form the staple of future practice, besides presenting to you a far greater number and variety of cases than the wards. The casualty department, too, must not be forgotten. There alone you will see the exanthematous and other rashes, sore throats, and cases of unusual character and sudden emergency, with special frequency and advantage."

The lecturer then offered the students some advice on the kind of books it would be best to read, and afterwards addressed himself to those who were drawing near to the end of their curriculum. "I may perhaps remind you, in the words of Sydenham, 'That the art of medicine is to be properly learnt only from its practice and exercise,' according to which definition your learning is now really about to commence. If, inspired by the philosophy as by the humility of this thought, you address yourself to the work before you, your success is certain—financially I trust, but, better than that, the success of real usefulness in life. Great responsibilities await you; but these are to be met by preparing for them, not by fearing them. And this preparation will be, and ought to be, a daily task: we must always be learning. Disease is no more stereotyped than are any other vital phenomena; and it speaks to us frequently, if I may say so in its *dialects*, which we must be as ready to understand as its ordinary speech. How needful, then, is it that we should carry forward the spirit of philosophical study with us through our daily round, and not degenerate into mere distributors of drugs—a work which the prescribing chemist or the quack can often do as well as we, finding, indeed, his *raison d'être* in our contentment with mere routine, a spirit which our patients too soon catch from us. 'You can always prescribe for him' I once heard advised to a student in a dilemma about the diagnosis, as a hint for his future practice. We may be very sure that it is of this spirit that is born the feeling in the public mind that blind empiricism is the best guide after all—a feeling the extent of which is witnessed by the endless columns of quackery in our daily papers." Alluding to the importance of the movement for the collective investigation of disease, Dr. Biss indicated three lines of inquiry, which, on account of their greater command of material, could be best worked out by men engaged in general practice—viz., (1) the varieties and relationships of the acute contagious disorders; (2) the real value and use of drugs in clinical treatment; (3) the complete examination and estimation of the value of family histories in relation to the etiology of disease. The lecturer concluded by exhorting his hearers to follow the example of the illustrious men whose names adorned the roll of *alumni* of the Middlesex Hospital Medical School.

UNIVERSITY COLLEGE.

INTRODUCTORY ADDRESS BY MR. A. E. BARKER, F.R.C.S., ASSISTANT PROFESSOR OF CLINICAL SURGERY AND TEACHER OF PRACTICAL SURGERY AT THE COLLEGE.

AFTER alluding to the tendency at the present day to disparage the custom of introductory lectures, the speaker pleaded for them that at least they afforded an opportunity of offering to newcomers launched for the first time on the wide sea of London life a hearty welcome on the part of their teachers, and the assurance that in all their difficulties they will have the sympathy of men who have trodden the same path before. If for no other reason than that these addresses helped to promote that personal cordial goodwill between teachers and students which ought to exist, and which is so apt to be tried, or actually to perish, in the hurry of the daily academical routine, they should be maintained and further developed. In University College especially, which gathered strangers from all parts of the civilised world, and where work is so absorbing, every means should be taken [illegible] Solly Le Gros [illegible]dents that they were welcome [illegible] be omitted of drawing closer the social bonds between all its workers. Addresses of this kind might be made of use, too, in introducing students to some of the questions which must sooner or later present themselves to those entering the profession. In this case those present were asked to consider some of the relations of medicine to society and the State, and then to survey the position now accorded to the medical profession by the latter. Two questions were first propounded as bearing especially upon this subject. First, whether medical effort as a whole really resulted in actual benefit to the human race; and, secondly, whether the influence of the medical profession strengthened the moral sense of mankind or weakened it. In answer to these questions, the speaker alluded to what the public require to be constantly reminded of namely, that their lives are daily protected and their happiness enormously increased by the discoveries of medical science as to the causation of disease as well as by the daily practice of the profession in relieving individual ailments. "The great laws of sanitation, embracing provisions for the prevention of epidemics and plagues, and the cleansing of cities in the wisest and most economical manner, the regulations regarding the examination of food with a view to the prevention of adulteration, and to secure its purity, all owe their inception and much of their elaboration to medical science." The remarkable reduction of the death-rate in large towns within recent years was pointed to as one practical outcome of all this. The immense diminution of suffering and death owing to the discovery of the causes of mortality after wounds and the introduction of the antiseptic methods into surgery were alluded to as special illustrations of the good reaped from medical effort. As to the question whether the moral sense of mankind is strengthened and elevated by scientific medical thought, it was pointed out that the profession is assailed by two different sets of thinkers from two opposite sides. One set asserts that the tendency of our teaching in physiology, biology, &c., is directly towards pure materialism, the other charge us with sacrificing strict reason and yielding in our life work solely to humanitarian sentimentalism and religious enthusiasm. The first reproach us with undermining old and revered beliefs, the second taunt us with committing inconsistencies and blunders, such as prolonging or saving lives rendered miserable by disease we are at present powerless to cure. Referring to these charges, the students were assured that neither is well founded, that the medical profession of all others is least open to the taunt of being carried on in defiance of reason, its whole work having a scientific basis; and that the sadder reproach of arid materialism is equally baseless in view of the spirit of lofty devotion to the older, grander principles of pure charity exhibited daily in the whole work of the profession. As to the charge of undermining the venerable and cherished beliefs of many, a few illustrations were furnished from medical [illegible] showing how some of their best doctrines [illegible] affirmed and rendered more intelligible thereby. As students then in this calling, beneficial alike to the bodies of men and to their moral being, the audience was invited to consider how far society and the State accorded that position to the medical profession which was its due, and what both were doing to further stimulate its beneficent energy. It was pleaded that society treated medicine with comparative coldness, that the fact that medicine was rapidly developing into a public service was not recognised, that the State encouraged it but little in comparison to other professions with no higher aims or practice. It was pointed out that while public thanks and public funds were often voted in Parliament to successful commanders and diplomatists, nothing equivalent was forthcoming for the great discoverers in medical science, whose work affected the lives and happiness of millions for all time. Even the less substantial though prouder honours of high position near the throne and hereditary titles were rarely or ever bestowed on medical men. It was suggested that the State might itself derive much benefit by the more public recognition of its achievements and by grants for the prosecution of further research, as well as by calling the highest minds of our profession into its councils officially. It was also suggested that the gracious Sovereign now on the throne, who has ever shown such a warm sympathy with all that ministers to the happiness and improvement of her people, might greatly encourage the medical profession by calling some of its leaders nearer to the throne and giving them a place on her Privy Council, or even among her peers. The result, it was contended, would be beneficial to the Upper House in

many ways, and would also benefit the nation when certain questions of legislation came to be discussed there. It was also thought by the speaker that the interest already occasionally shown by members of the Royal Family in the greater meetings of medical men, if more frequently exhibited, and especially in the annual gatherings of medical students, might stimulate the public to sympathise more with medical life a matter in which the whole nation is very deeply interested. The same personal interest that is shown by our Royal Princes in the doings of the army, the legal, and even in the musical and other artistic professions would not be thrown away if bestowed upon medicine. But while these things were put forward as worthy of the attention of society, of the State, and of the Crown, the prospect of their being granted was not held up as an inducement to younger men to enter the medical profession, and to devote themselves to it. The divine science and art of healing contained in itself the highest of all rewards worth seeking. It offered to the highest intellects problems which should carry them into the deepest mines of research or up to the loftiest regions of speculation. It offered also to men of warm sympathies quiet walks in the valley below amid the homes of men, where they would have the freest outlet for all their purest impulses, the widest field for kindly, patient, useful activity for others. It offered, in short, to all earnest men work of the best kind suitable to their particular bent, and if old Carlyle's saying is true, that "blessed is the man who has found his work, let him ask no other blessedness," Medicine has indeed the highest reward for all her sons.

WESTMINSTER HOSPITAL.

INTRODUCTORY ADDRESS BY MR. JAMES BLACK.

THE introductory address was delivered by Mr. James Black, B.A., F.R.C.S., lecturer on anatomy at the new schools in Caxton-street, Westminster, on Oct. 4th, at 3.30 P.M. He stated that he thought the time placed at his disposal would be most profitably employed in offering a few words of practical advice to those who were commencing study for the medical profession, and some suggestions relative to preliminary training and future prospects. One of the first questions arising was how the student should profitably employ his time. The answer to an extent was furnished in the prospectus, where he would discover that most of the hours of the day were mapped out either for attendance at lectures and demonstrations, or for practical work in the dissecting room and chemical and physiological laboratories. Students, however, quickly discover that, even then, their labours are not at an end; but that extra hours must be spent in reading over those subjects which had occupied the mind during the day, and which would be quickly forgotten unless subjected to methodical and critical reflection. The inquiry also arose, should there be no time for recreation and out-door exercise? The reply was undoubtedly there should be, for a curriculum defective therein must inevitably produce pernicious results. From his experience at Cambridge the lecturer advised that a moderate indulgence in athletic sports was well calculated to develop the student's physique as well as cultivate his mind. He complimented the school on the fair success which had attended their efforts in the public competitions, and referred particularly to the case of one gentleman who upheld the credit of their hospital in the sports, also carried off the exhibition, scholarship, most of the prizes, and, what would prove of the greatest value of all to him, was in turn elected to several valuable appointments in the hospital. Concluding his remarks on this subject, with the caution that such devotion must be circumscribed within due limits, Mr. Black spoke a few words on music and drawing, which he strongly advised his hearers to cultivate. Music was a special blessing; it afforded the most perfect solace to the jaded intellect. As Dr. Clouston, in his address on Psychology before the British Medical Association at Brighton, explained, "Intense thought will inhibit emotion; whilst, on the other hand, intense attention to objective sounds will inhibit thought." The medical profession included within its ranks many who, to judge by the excellence of their art work, had reached the pinnacle of fame as artists, and who, none the less, had attained an exalted position in their own profession. Dr. Oliver Wendell Holmes, whose recent visit had reminded us that literature too, has for one of its brightest ornaments a member of our profession, happily remarked—"Literature is a good staff to walk with, but not a good one to lean upon. Coleridge had told him, 'Every man should have as well some fixed and regular occupation,' and this advice he would hand on to any who might feel tempted to exchange the steady preparations for a practical career for the uncertain pathway of a literary life." Edward Jenner, one of the greatest benefactors of mankind, often solaced himself, when the cares connected with the progress of his discovery weighed upon him, by playing on the violin and flute with all the mirth of youth. Whilst, then, avoiding unmitigated study, the student should vehemently despise the wanton recklessness of uninterrupted frivolity. To those who could not help working, even at the expense of their bodily and mental powers, he would say, Guard against this as much as possible by systematically taking a good night's rest and sacredly observing the Sabbath.

To proceed to the course of studies, the field open to the medical student was endless in variety, as was illustrated by reference to the following, among other subjects: anatomy, physiology, and chemistry. Allusion was made to the researches of Fraser, Crum-Brown, Lauder Brunton, and others, who have established a scientific explanation of the action of different substances founded on the investigation of their molecular constitution; a distinct connexion being proved to exist between the specific atomic grouping of these bodies and their physiological action. And Mr. Cresswell Hewett's remarkable discovery of the synthetical manufacture of quinine, by which the price of the drug was likely to be reduced to something like 3*d.* per ounce, was also referred to. A certain amount of natural science, physical and biological, the lecturer thought, should be acquired before joining a hospital school, and he sketched out a preliminary course founded on the lines lately laid down by a committee of naval instruction for the preliminary training for the navy. At fifteen an examination equivalent to that for the lower certificates conducted by the Oxford and Cambridge School Examination Board was to be passed. For the ensuing year the boy should remain at his school and specially devote himself to mathematics, physics, modern languages, and drawing. At sixteen, when the above committee decided the naval cadets should join the *Britannia* training-ship to pursue a year's course of technical and nautical instruction preliminary to the succeeding three years spent afloat, when, of course, their studies would be strictly practical and professional. Mr. Black proposed that the candidate for the medical profession should attend some well-equipped laboratory for the ensuing twelvemonth, where he was to be practically taught biology, chemistry, and physics. Certificates should be required of having undergone such a preliminary training, and the student be expected to matriculate in the above subjects on entering a hospital school. The lecturer, whilst profoundly appreciating the value of a thorough classical education, could not but feel convinced that by adopting some such course as the above there would be more likelihood of the student successfully completing his present curriculum in the allotted four years, and that the benefit of a satisfactory preliminary scientific training would become universal, whereas such is now too much limited to those only who intend taking a university degree. Referring to future prospects, he congratulated his audience on the chance there seemed of taking an M.D. degree in London on the same conditions that already existed at certain universities. The corporation of the venerable College of Physicians and the illustrious College of Surgeons amply provided England with a truly representative body, admirably suited to confer an M.D. degree on all really well-educated metropolitan students.

In conclusion, Mr. Black observed that the success of their own school depended mainly on themselves—not less upon the students than those who were members of its staff. All must be actuated by high motives. The splendid site of the hospital, under the shadow of that Abbey where lie the ashes of the good and great, the long roll of eminent men who devoted their services to the good work done in the hospital, and, lastly, the enormous vitality which had enabled the school to survive the crushing blows it had received during its existence of half a century, and to appear as it now did, must inevitably inspire them all with enthusiasm to do their [redacted] maintain the traditions of the past.

ROYAL VETERINARY COLLEGE.

IN his introductory address Professor ROBERTSON referred to the changes which had taken place in our views of matters purely biological and pathological. In both human and veterinary medicine, he remarked, the elaboration of the germ theory of Pasteur in its earlier triumphs in the department of surgery is likely to be surpassed by what we may reasonably expect will yet be achieved in the domain of medicine. In preventive medicine, as applied to animals, the recognition of the specificity of many of those diseases which have attracted attention through their destructiveness has given us a solidity of basis in dealing with them which was unattainable while they continued to be regarded as the result of variable influences, sanitary and dietetic. Professor Robertson afterwards directed the attention of his audience to the arrangement of the students' curriculum in its two great divisions of theory and practice, exhibiting the relation of one to the other, and pointed out that no facilities, however abundant, nor teachers, however good, would of themselves be sufficient to enable anyone to secure the ends contemplated unless they were supplemented on the pupil's part by earnest work and the exercise of observation and reflection upon all the facts, physiological and pathological, which they encountered.

SHEFFIELD SCHOOL OF MEDICINE.

INTRODUCTORY ADDRESS BY DR. WILLIAM S. PORTER, LECTURER ON PHYSIOLOGY TO THE SHEFFIELD SCHOOL OF MEDICINE, AND PHYSICIAN TO THE SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.

DR. PORTER, after defending the retention of an introductory lecture and welcoming the new students, said that they had chosen a profession which only offers very limited rewards in a worldly sense, which would make great demands upon their powers of physical and mental endurance, which would impose upon them duties and responsibilities requiring the exercise of much delicacy, tact, and discretion; and which might expose them to personal danger, and their reputation, and even liberty, to some risk. What, then, is there to counterbalance these disadvantages? Pecuniarily, an honourable competence, if nothing more, the medical profession does offer with tolerable certainty; intellectually, a wider and more interesting field for study than almost any other vocation; and, if pursued conscientiously and faithfully, the esteem and gratitude of many of their clients and the reward of an approving conscience. In the words of one who has left us for all time the memory of an honourable and upright life, and the classical productions of his pen, the late Sir Thomas Watson: "It affords ample scope and exercise for the intellect, and is conversant with objects that tend to elevate the thoughts, to chasten the feelings, and to touch the heart." Although it may be undertaken from no higher motive than that of earning an honest livelihood, it is a profession which affords greater scope than most other vocations for the exercise of philanthropy; and it is in availing ourselves of the opportunities afforded us of doing good and unselfish work that we can establish its claim to the attribute of nobility, with which on these occasions it is customary to invest it. It is in the sacrifice of our own comfort, and even safety when necessary, in the interests of those committed to our care; in the little acts of kindness, forbearance, and consideration to those who have, perhaps, only their gratitude to offer in return, that the higher ideal of our vocation is realised. He was not one of those who see very much to grumble at in the social status and position which are accorded us as a profession. We are not a wealthy body, and cannot expect to compete with the advantages which wealth confers; and in this respect we rank much as other professional men do. As individuals, general culture, education, and some advantages derived from early associations and training will always obtain recognition; and the position which a man's individual qualities win for him is more satisfactory than one which is accorded him in right of his profession. If he is a gentleman, and shows that he is actuated by gentlemanly instinct in his private and professional relations with others, he needs no table of precedence to maintain his rank and is above the disparagement of vulgar minds. But as it is that which cor[illegible] man that defileth him, so is it the acts of [illegible] profession themselves that lower their vocation in the eyes of the public. Let it be the aim of each one to maintain the traditions and honour of the profession in his relations to the public, to his patients, and to his medical brethren; that when his race is run he may hand on that honourable heritage to his successors with the knowledge that it has never been disgraced by any act of his. After briefly sketching the curriculum and advising his hearers as to their studies, Dr. Porter entered into a long and eloquent defence of vivisection, and, alluding to Ferrier, Pasteur, and other workers, pointed out the benefits which the world has reaped from their investigations, which could not have been carried out without experiments on animals. "More recently," said the lecturer, "Professor Ferrier and others have made most important discoveries in connexion with the localisation of function in the brain by experiments upon animals. These experiments have not only furnished us with the means of diagnosing, in some cases, the exact situation of a tumour or other local lesion in the brain, but they have also demonstrated the fact that such lesions are within the reach of operative surgery." The concluding words of the address were as follows:—

"Gentlemen, there is a great future before us as a profession, a future which is already beginning to take very definite shape. Great social and physiological questions are casting their shadows before them, and the public are learning to look to us for advice upon matters which concern the health and prosperity of the nation as well as the single interests of the individual. Public health is yet an infant science; let me urge upon you all the importance of its study. The prevention of disease, although it may be the means of cutting down our own incomes, claims a natural precedence over the curative department of our art. One of the social problems of the day is what is known as the alcohol question. And it is not merely the effects of alcoholic excess upon the individual, but the effects transmitted to the race by heredity that brings this question within the domain of public medicine. We have long been familiar with the degenerative lesions in tissues and organs and their consequences produced by long-continued and excessive indulgence in alcohol; but we are only beginning to realise fully, in connexion with this question, by the study of mental disease and brain pathology, the awful fulfilment of the threat that the sins of the fathers should be visited upon the children. We know now how this tendency to degenerative change in the delicate tissue of the brain may be handed down from generation to generation, unless corrected by other hereditary influences and healthier modes of life; and how much mental and moral instability, as well as actual insanity, may be assigned to such a heritage..... In the course of your clinical studies regard alcohol in the light of a drug, often an invaluable one, and notice particularly in what sort of cases and for what conditions it is prescribed, that you may apportion it its proper therapeutic value, and not use it recklessly or indiscriminately. We, as a profession, have often been charged with fostering a passion for alcohol by ordering it indiscriminately; but I believe that such charges generally come from those who seek to excuse their own weakness and want of self-control. Be especially careful how you prescribe it in the case of children and young persons, or for those in whom there is reason to suspect an inclination to indulgence in alcohol, opium, or chloral, for the craving for any of these is an indication of the same essential condition of brain. In treating those who are addicted to alcoholic excess the employment of moral therapeutics is mostly called for, and may not we as medical men do something in this direction? Let us at least endeavour to ward off temptation from those in whom we have reason to suspect an hereditary tendency. Here it is that teetotal organisations come to our aid, and we cannot too gratefully acknowledge their help as a means of voluntary restraint under such circumstances. With those upon whom this vice has fastened we have much less hope of success; but the only course to pursue, I believe, is to insist upon as complete abstinence as possible. I have heard the objection urged, that if you do so your patient will probably leave you and go to somebody else, who is, perhaps, less conscientious and more indulgent to his weakness. Well, gentlemen, I think it is a question of your duty to your patient to advise him for the best; and the fact that others may not be so scrupulous does not absolve you from the obligation to do your duty at whatever cost. Your studies may, not unnaturally, lead you to reflect upon the relations

of theology to scientific teaching. The progress of science has led some of its most distinguished votaries to seek in natural laws the explanation of all that has been hitherto regarded as evidence of supernatural existence, and to refuse credence to anything which is insusceptible of proof. There is in the human mind a natural desire to probe everything to the bottom, and a yearning after finality which tempts us to hasty inferences and conclusions. There are epidemics of opinion as there are epidemics of disease, and the world's history shows us many such instances of waves of infidelity and doubt. The deeper scientific investigation penetrates the more the unity of nature is becoming apparent. In the words of Sir James Paget, 'As the rays of knowledge have extended and diverged, so has their relation to one common centre become more evident, and the unity of nature has become more significant of the unity of God.' Let us rather hold by our faith, and wait in patient confidence for the light of further knowledge. If we renounce our faith, what have we left to live for?

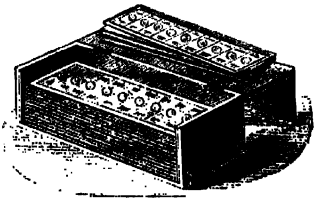
> 'Work without hope draws nectar in a sieve,
> And hope without an object cannot live.'

The spread of materialism warns us that we are in danger of drifting into the realisation of Pope's prophecy in the closing lines of the 'Dunciad':

> 'Lo! thy dread empire, Chaos! is restored,
> Light dies before thy uncreating word.
> Thy hand, great Anarch! lets the curtain fall;
> And universal darkness buries all.'"

UNIVERSITY COLLEGE, LIVERPOOL.

PROFESSOR CONWAY, in delivering the introductory address on "The Succession of Ideals," said the spiritual and intellectual products of the human mind are different at different times and in different places. It is with humanity as with individuals. No one is the same at any two moments. What a man strives and hopes, and even lies and sins for at one time, may be unattractive, may be hateful, to him at another. No conception returns unmodified to the mind. Do what he will, his work repeated results in something new. The ideals of youth, of middle life, and of age, how they differ one from another—differ as widely as the ideals of different men. As with the individual, so with the nation, with the race, and the sum of the races. That which mankind as a whole, or which nations as a whole, have at any time striven after, in so far as they have attained it, enters into the sum of human possession, and may become the property of the individual; nay, if it has once produced a moulding effect upon the race, heredity stamps the sign of it on the babe unborn. Any study, if pursued to the end, leads on to all other studies. Any fact may be chosen as the centre of all knowledge, because whilst the area of what is known is limited, the universe or possible knowledge is infinite. But the boundaries of the known are constantly enlarged, first in one direction, then in another, by the passionate striving of men outwards. The goal-point of one generation's endeavour becomes a detail in the possession of the next. The centre of effort changes, but that which has been a centre ceases not to exist, because the forces of humanity bear past it instead of upon it. A fact does not become more true by being known, nor an ideal more fine because men strive towards it. Whatever part of any ideal is true and good remains for ever a possession of mankind. Every ideal worthy of the name manages to get itself enshrined in some form that would endure if only men cared to preserve their heritage from the past. He that destroys a thing that another once laboured to make murders a dead man. An honest carpenter may continue the influence of his honesty long after his death, if the work he had done be respected by those privileged to use it. If they wilfully destroy it, the good man's influence is at an end. The work of the dishonest clears itself speedily enough away. We may destroy what we please, and leave behind whatever wilderness seems to us good to be our record in the face of eternity. The noble works of noble men once formed we may demolish, and so make the desert about us more complete. Their noble deeds once done we may forget; but works and deeds are beyond our power to annihilate; they have a larger and higher existence there where the hand of man reaches no more back to wither and destroy. Dreaming of such an existence, and of such only, is it possible to say to any man, or race, or civilisation, or ideal, *esto perpetua?*



LEEDS SCHOOL OF MEDICINE.

THE REV. F. J. JAYNE, vicar of Leeds, said that whilst trying to find and think out some appropriate topic for this introductory address, he was at the outset impressed by the very large amount of ground common to the various departments of education and the different professions. What is true of one is found to be true, with a few obvious modifications, of all. The physician must possess certain mental and moral qualities—promptitude, discernment, firmness, and the tact which can bring men and circumstances to contribute towards the end he has in view. The learning of the specialist may be profound, his enthusiasm pure and ardent, his instruments and appliances the best that money and contrivance can procure, yet if he lacks the practical wisdom which will enable him clearly to read and deftly to handle those with whom he has to do, he will be baffled and daunted by difficulties of no real moment, he will cause confusion where he should have established confidence and order; he will fail where others, in some respects his inferiors, would have achieved a conspicuous and solid success. We must not be content with a commonplace and low-pitched estimate of the end towards which we are moving. In the very childhood of the medical art a clear and lofty conception of its functions and responsibilities was formed and established. Having briefly sketched these responsibilities, Mr. Jayne impressed upon his hearers the importance of cultivating those moral and spiritual qualities in the absence of which our opinions may, indeed, have the subtlety and brilliancy of the advocate, but not the impartiality and authority of the judge.

New Inventions.

NEW PORTABLE CABINET FOR MICROSCOPIC SLIDES.

MR. MEDLAND, of the Borough, London-bridge, has forwarded for our inspection a specimen of his new portable cabinet for microscopic objects. Its chief recommendation is the circumstance that without greatly increasing the size of the ordinary cabinet (which can accommodate six dozen

slides), the new box can enclose, without more than the usual risk, twice that number. Each glass slide is secured in its place by part of a long flap that projects for a quarter of an inch or so over each end of the oblong slide. This arrangement may with advantage be made more efficient by means of slips of elastic ribbon, which should cause the flaps to snap back after any desired slide had been removed. The price of the cabinet, which is cased in polished pine, is *7s. 6d.*

POISON GUARD.

MESSRS. PITTUCK and SNOWDON, of Hebburn-on-Tyne, have recently patented an appliance which is intended to prevent the accidental handling and unintentional dispensing of poisons. The apparatus, if such a simple, though withal effectual, contrivance merits a name of such dignity, consists of a brass collar to be fitted to the bottle neck, and a perpendicular slide consisting of two bars, which pass, one on each side of the handle of the stopper, and so keep the stopper base firm in the neck of the bottle. When this fastener is used, the immunity from error through unwittingly dispensing poisons from ignorance or absent-mindedness is complete. No one can remove the stopper from a bottle to which this guard is fitted except by a deliberate act requiring the use of both hands. Druggists and medical men who dispense their own medicines [redacted] protect their poison bottles by mean[redacted]

THE LANCET.

LONDON: SATURDAY, OCTOBER 9, 1886.

THE recently published annual report of the Metropolitan Board of Works illustrates at once the strength and the weakness of the great London sanitary authority. The work entrusted to the Board by scores of Acts of Parliament is enormous both in extent and magnitude, and all agree that a great part of the work is done well. Theoretically Parliament has, of course, control over the Board, but none is in practice exercised, and for more than thirty years every successive Act has increased the powers of the metropolitan authority. Questions are occasionally asked in the House, but the usual official replies are always forthcoming. Either the Board "will make the necessary inquiries," or "it has the matter under consideration," and neither Parliament nor the country takes any further trouble. The apparent indifference of the public to the proceedings of the Board in matters of vital moment is indeed remarkable. It is based, we venture to think, less on unlimited trust than on imperfect knowledge, and a conviction, founded on experience, that interference would be useless. The annual report affords abundant evidence in support of this view. It is absurdly meagre considering its immense range, and the evidence given in support of its statements is often most vague. Frequently, indeed, no evidence of any kind is adduced. The conclusions to which the Board in its wisdom has arrived are stated in few words and with ample self-confidence, even in matters on which there is the widest difference of opinion among scientific men; but the reasons which have led to those conclusions—reasons based, we are told, on elaborate scientific inquiry—are barely indicated in few lines.

We submit that all this is profoundly wrong. That the scientific advisers of the Board have made important experiments we know, and we know also that, being men of great skill and high repute, their experiments are valuable contributions to sanitary science. Whether other sanitarians agreed or disagreed with the inferences, they could not fail to be benefited by a study of the researches. Why, then, are these researches withheld, and with them the written opinions of the eminent scientific authorities who have been consulted? The Board arrogates to itself the position of a private company trading with its own capital, whereas all the world knows that its money is public money expended in enormous sums by a public department. Whatever scientific evidence is gained by the expenditure is public property, and should be available, not only to Londoners, but to the whole civilised world. There is another assumption even worse than this in the position taken by the Board. It assumes the right to wage war against those who on scientific grounds venture to differ from it, as though they were guilty of heresy. And the war is not waged fairly; for the arguments of the opponents are not duly set forth, and are only met by dogmas based on evidence alleged by Solly Le Grus. The defendant in a civil action would [illegible] adopting such a course, and it is palpably absurd in a body created by the Legislature and supported by the money of the ratepayers. If the policy of the Board be right, why object to showing the grounds on which it is based? If it be wrong, who will be damaged by its modification?

These criticisms apply to many parts of the report before us, but above all to the two or three scanty pages which are entitled "The Sewage and the River Thames." This exceedingly important question was, as our readers are well aware, forced upon the attention of the Metropolitan Board of Works by the reports of the Royal Commission on Metropolitan Sewage Discharge, which was presided over by Lord BRAMWELL. This Commission, in two reports—the second even stronger than the first,—condemned the system of river pollution which the Board devised, and which during the sitting of the Commission it defended with elaborate evidence and at enormous expense. The Commissioners, among whom were three distinguished chemists, two of them physicians, decided against the Board after a most protracted inquiry, and advised in the most forcible terms that the sewage of London, which polluted the Thames throughout the whole tidal area, should be carried down to a suitable spot in Sea Reach, there *purified*—the italics are important,—and afterwards thrown as a clear effluent into what would practically be an arm of the sea. Parliament is, most unfortunately, for the present, unable to deal with great social questions such as this when they involve matters of controversy. Ireland and Egypt, not to speak of Bulgaria and Burmah, make it impossible to do anything for London, and so the matter was referred to the Metropolitan Board of Works, although that body had spent an enormous sum in opposing the conclusions finally adopted unanimously by the Royal Commissioners. What the Board has subsequently done is about what might have been expected. It is set forth with almost contemptuous curtness in the present report. One point is, indeed, conceded in face of the overwhelming testimony adduced before the Commission. It is no longer pretended that the pouring the sewage of all London in a raw state into the Thames near Woolwich is no injury or danger to the river. Many witnesses, indeed, asserted as much before the Commissioners; but the Commissioners themselves inspected the river, and as several of them were half poisoned by the stench, and recorded the fact, the contention had to be abandoned. The first line of defence was, after hard fighting, found to be untenable, but another as near as possible to the old was at once adopted, and there in its new ditch the Board at present remains entrenched with a new show of obstinate valour.

This second line may be shortly described as follows. The present outfalls are to be retained. Barking and Crossness, and the New West Kent outfall opposite Purfleet, are, it seems, essential, in spite of the very strong opinion of the Commissioners to the contrary. But in a leisurely manner "purification" is to be adopted at each outfall. Some portion of the solid matters is to be precipitated with sulphate of iron and lime. After settling for "an hour or two" the effluent is to be thrown into the river. The first idea evidently was to throw it in without further treatment, but as, in the opinion of the chemists consulted, "in hot weather something more would

be necessary to ensure complete immunity from offensive effluvia arising from secondary fermentation"—in other words from putrefaction,—it was decided to treat the effluent with permanganic acid (that is, with a mixture of manganate of soda and sulphuric acid) before sending it into the river. As to the sludge, of which even after pressing there would be 850 tons daily, the Board properly despairs of disposing of it in the vicinity of the outfalls. It therefore proposes to purchase steamers of suitable construction, which shall carry the objectionable deposit out to sea; to what part of the sea we are not told. Then follows in the report a passage of almost child-like simplicity in regard to the alternative scheme of carrying the sewage further down the river. This scheme was submitted to the Commissioners by Sir JOSEPH BAZALGETTE, the engineer to the Board, who, by-the-bye, on a previous occasion had declared it to be impossible. It involves, of course, more expense than the present dirty system, even with its proposed modifications, but the expense would be a small matter for London, and it was strongly and unanimously recommended, as far as its main features go, by the Royal Commissioners, among whom were some very eminent engineers. It is dismissed by the Board in a few lines. The Board objects partly on the ground of expense, but mainly, as we gather, because Southend objects. Surely the force of absurdity could no further go. The Board maintains, first, that the sewage of all London thrown raw into the river near Woolwich does not damage the river; secondly, that any possible sentimental objection may be removed by purification at the outfalls; and thirdly, that the discharge of sewage in Sea Reach would be an irreparable injury to Southend. The Board calmly ignores the condition insisted on by the Royal Commissioners, that even at Sea Reach the sewage ought to be disinfected before entering the river. In Canvey Island, or near it, both the sludge and the effluent could be effectually, economically, and conveniently applied to the land.

OUR readers will learn from letters we publish elsewhere that the committee formed to promote the election of Dr. GLOVER to the Medical Council has been asked to join what is now known as the Birmingham Committee, who resolved last week to adopt as their candidates Mr. WHEELHOUSE, Sir B. W. FOSTER, and Dr. GLOVER. After due consideration this invitation has not been accepted, and the two committees remain separate, each to pursue its own particular aims. The reasons alleged by Dr. GLOVER'S committee for this decision are in our opinion conclusive. Some of his supporters are already pledged to other candidates, while many others "decline to have their freedom of selection curtailed." It is this latter point which must be steadily kept in view. Unless the general body of the profession determines resolutely that it will not brook any limitation of the most perfect freedom of selection of its representatives, there is a great danger that the gift of direct representation will become worthless. For years we have been suffering the disadvantage of having a Council composed of men chosen in a very large proportion by the governing bodies of medical corporations and universities. Matters will not be mended if to them are added other men selected by a small self-appointed committee, and who will be able to pose as the representatives of the thousands in the ranks of general practice. All registered practitioners must be careful to exercise their new right independently, and not submit to the dictation of a committee which assumes to itself the power or the right of selecting the most eligible candidates. We believe that the feeling in favour of a perfect freedom of selection is very strong, and that if this feeling is tampered with a storm of remonstrance will be evoked from the constituents. By all means let us have candidates recommended as suitable for posts on the Council by committees of their friends and acquaintances; but this having been done, let the selection of the three who are to represent the practitioners of England be left absolutely free and unfettered.

Of the merits and claims of individual candidates, it is perhaps not the time to write fully. We would deprecate an early pledging of votes. Better is it for an elector, when canvassed, only to promise to consider well the claims of the candidate in question, and then to vote only for those who will most surely express at the Council the views of the great electorate. An intimate acquaintance with the duties and responsibilities of general practitioners is a prime requisite in a good candidate. A knowledge of the past work of the Medical Council, of its duties, its powers, its resources, and its defects, is scarcely less valuable. A desire to advance the highest welfare of the profession and to free it from all that savours of charlatanism and chicanery is also important. Mere professional eminence and merit, praiseworthy as they are, will not must not be accepted in lieu of these requirements.

AT the recent Congress of the Sanitary Institute Dr. SEATON read a paper on the Notification of Infectious Diseases, as to which he had, in his former capacity of medical officer of health for the borough of Nottingham, a somewhat wide experience. He takes it for granted that, both on the part of the medical profession and on that of the public generally, the need for notification is generally admitted, and in this view he is doubtless correct. But the progress which is being made in the extension of the system is slow, and this tardiness is due to a number of difficulties with which the subject is surrounded.

In the first place, the actual utility of compulsory notification in preventing the spread of infectious diseases is, in several respects, not so marked as had been anticipated. Where such diseases as cholera and small-pox are concerned, there is, except perhaps as regards the latter disease in the metropolis and some large cities, little difficulty in securing notification and in dealing with the sick; but when scarlet fever, the most fatal perhaps of our current infectious fevers, is in question, it is extremely difficult to show that, apart from such general diminution as has during the past few years prevailed throughout the country, any material result has followed in the towns where the system of notification is in operation. Such result as has been obtained relates rather to a diminution in the percentage of deaths to attacks than to any falling off in the number of cases. It must, however, be remembered that the system of notification has not very long been in operation, and the [redacted] which has elapsed may scarcely have [redacted] of any material

effect on an infection which has acquired the firmest possible hold on the inhabitants of our towns. Then, again, such failure as has followed on compulsory notification must, to an important extent, be set down to the want in many districts of any efficient sanitary organisation for dealing with the diseases notified. There are, indeed, towns which have made little or no use of the special powers granted to them, and which have not so much as a decent hospital for the proper isolation of first attacks of such infectious fevers as constantly occur in their midst. Neglect of this sort tends largely to bring the whole system into serious disrepute, and although we do not doubt that some good may be done by way of controlling school attendances and otherwise, where notification is not followed by any efficient isolation and disinfection, yet we are inclined to think that in the long run it would be advantageous if powers of compulsory notification were withheld from all authorities until they had shown their intention to make proper use of the information they wished to acquire, by providing an appropriate hospital and some efficient means of disinfection.

The difficulty of deciding who is to give the notification to the sanitary authority must also be regarded as a prime obstacle to any rapid extension of the system. Dr. SEATON, as an officer of health, evidently feels very strongly that the medical practitioner in attendance on the case is the proper person to make the notification, and he instances the case of Greenock, where notification has had to be made by the householder, as typical of the failure of the latter method. A perusal of the current reports of medical officers of health favours the same conclusion, and in the towns where notification is required both of the householder and the medical man, it is admitted that the former is rarely or never required to make it, and that it is almost invariably effected by the latter. But at the same time it must be remembered that there is a strong feeling on the part of a large number of medical practitioners that this duty should not be imposed upon them by the Legislature, and until they can view the matter in the same light as the medical officer of health does there will probably be no very large extension of the system. But notwithstanding all the drawbacks which attach to the compulsory notification of infectious diseases, as now carried out, it is certain that for the class of disease of which enteric fever is the type much good has been done, and more still is in progress.

The inspection of premises which follows on the notification of such diseases has revealed a large number of defective sanitary conditions which would otherwise never have been discovered, and the action which has been taken to secure their abatement has greatly tended to an improvement of the circumstances under which the people are living in the sanitary districts where exceptional powers as to notification are in operation. Works of water-supply, sewerage, and of house drainage, the prevention of overcrowding, the control of dairies and the sale of milk, have all been materially facilitated by the discovery of infectious diseases under conditions which have called for action on the part of the sanitary authority; and even if this were the only result [illegible] by notification, it would be an im[illegible]as not yet come when it can be shown that all the results originally claimed for the system have been brought about.

There is one part of Dr. SEATON's paper with which we cannot agree. In dealing with the question of providing means of isolation for the diseases notified, he admits "the fact" that small-pox has been found to be most prevalent in the neighbourhood of the large London hospitals," and then, curiously enough, he rather complains of "a most unreasonable fear of the dangers which may arise from an infectious hospital." We think that "the fact" he refers to makes the fear of small-pox hospitals most reasonable. But, in maintaining the contrary opinion, Dr. SEATON goes on to state that it has been shown that the experience of the country towns is altogether opposed to that of London. We know of no such proof. But we do know that this same view of the harmlessness of London small-pox hospitals was held quite as stoutly as that relating to the country ones is now maintained, until the metropolitan hospitals were put to a test to which no other hospitals in country districts have been subjected. And further, whatever be the cause which leads to mischief around small-pox hospitals, we believe it has operated as regards several country as well as London hospitals. There was a large incidence of small-pox around the Oldham Hospital; the same has been alleged at Birmingham, and, curiously enough, although maps are issued showing the incidence of other infectious disease in various parts of the borough, the reports give no such information as to the localisation of small-pox. And again, a careful perusal of Dr. SEATON's own paper before the Epidemiological Society as to small-pox in Nottingham leads us to believe that if the rate of attack per house in the different zones around the Nottingham Hospital had been calculated in the same method as that adopted by Mr. POWER in his masterly report on Fulham, the case of Nottingham would, in all probability, have afforded a striking proof of the truth of Mr. POWER'S conclusions. Until country small-pox hospitals have been subjected to the same crucial test as the metropolitan ones have been put to, the less that is said about them the better.

TRULY there is no limit to the application of the term "hysteria." The Clinical Society during its last session listened to the doctrine of hysterical hyperpyrexia. This was by an English observer, Dr. HALE WHITE; and now a French observer, M. DEBOVE, is discoursing on hysterical apoplexy. There is right and there is wrong in the use of this term to express the phenomena to which the English and the French physicians wish to draw attention. We think that the word "functional" would be preferable even when the ordinary phenomena of hysteria are under discussion. M. DEBOVE speaks of apoplexies due to the influence of lead, mercury, and alcohol as also hysterical. The essence of the controversy lies in the nutshell of a name. There are in the brain certain centres having certain functions, which may be deranged by organic and by non-organic causes—i.e., irremediable and remediable or removable causes. A hæmorrhage may abolish certain functions by placing *hors de combat* certain structures exercising those functions. It is conceivable that the same structures may be the seat of intrinsic disabilities leading to

an overaction or cessation of action. And the same structures may be excited to overaction or inaction by toxæmic conditions. Is there any good reason why we should style a paralysis "hysterical" because we cannot ascertain the cause that has led to the inactivity of the paralysed centre? If the etymologically unfit word is to be retained at all, its use should, in our opinion, be limited to describe those cases in which there is every reason to believe that the affection has been brought about as the result of an inherently faulty condition of the nervous protoplasm, such as is inferred when we recognise the existence of the well-marked neuropathic disposition. For all this, the case which M. DEBOVE described as hysterical apoplexy is full of interest. The following is an outline of the case. A man aged thirty-one, whilst walking away from the dinner-table, suddenly lost consciousness and remained in this state for twelve hours; no convulsions appeared to have occurred, the lumbar centres of the cord did not give way (or at least neither defecation nor micturition was noted), and the limbs remained relaxed. At the end of the period of unconsciousness the left side of the body was found to be paralysed, and there was absolute loss of sensation in the whole of the left half of the body, including the special senses. The paralysis of motion disappeared considerably in the course of a few hours, so that there was but some weakness on the next day. The hysterical, or, as we should prefer to call it, "functional," nature of the affection is proved by the circumstance that the defect of motion and the loss of sensation could be made to pass over to the opposite side of the body by the employment of any of those agencies that are ordinarily effective in the causation of the phenomena of "transfer," and by the further fact that the whole of the symptoms disappeared in the course of a few days. One more principle should be borne in mind: "hysterical" phenomena are not unfrequently met with in cases of genuine organic disease of the brain. It is important to add that M. DEBOVE'S patient was in the marine service, and had never been known to suffer from any phenomena that could be classed under the heading of nervous—surely an argument against labelling his case as one of hysterical apoplexy. But there is some consistency in M. DEBOVE'S method, for he apparently designates most functional paralyses by the same inappropriate adjective.

Annotations.

"Ne quid nimis."

THE GENESIS OF TYPHOID.

TILL within the last fifteen years Rome stood conspicuous among European cities for her exemption from gastro-enteric fever, and yet she had many of the conditions which favour the rise and progress of the malady—a town council whose neglect of sanitary law had passed into a by-word, and periodical overcrowding from the hordes of pilgrims that even in Dante's time formed a veritable "army" of conscientiously filth-despising, flesh-crucifying ascetics. With every facility for its being imported and effecting a foothold in the Eternal City, typhoid was known to Baglivi, Lancisi, Puccinotti, Valentini, Folchi, and other great Roman physicians only from foreign treatises or correspondents never in their own practice, whether private or in hospital. True, there were acute fevers, there were "subcontinuous remittents"; but their response to treatment, hygienic and clinical, proved their absolute non-connexion with typhoid. The Leonine City, for instance, was visited by a fever which, in Lancisi's time, swept away 2000 victims in three months, but which disappeared under the prompt measures of that eminent physician—the draining of the moat of Castle St. Angelo and the exhibition of Peruvian bark. Besides this fever described by Lancisi as "febris castrensis" from its association with the stagnant water of moat-defended garrison-towns, there was the "febris hemitritæa," or semi-tertian remittent, which Liebermeister has tried to classify under "typho-abdominal." But even this, both in symptoms and in response to treatment, was not a true typhoid, and is described by Petroni, a predecessor of Lancisi's in Rome, as occurring very rarely (*perraro*), and by Lancisi himself as only epidemic when an inundation of the Tiber had preceded it; while Professor Valentini, an eminent authority for the first half of this century, says of it: "Nostris temporibus fere nunquam observatur." The statistics of the Roman hospitals afford further proof of the city's immunity from typhoid till within the last decade or so, these hospitals lying low and very inferior in construction and sanitary appointments to those of London, or even Paris and Vienna, yet hardly ever exhibiting even an imported case of typhoid for the instruction of the students. But now all this is changed, and in the new quarters of the city which have sprung up since 1870 typhoid is getting far from rare. The introduction of English waterclosets into the Roman dwellings is, by common consent of the local physicians, the cause of this formidable importation. Dr. Fattorini has recently published an able essay on the genesis and propagation of typhoid in Rome, and traces the appearance of the disease to the sewage poison for the first time finding its way into the drinking-water of the inhabitants. "The ancient Romans," he says, "knew nothing of the microscope nor of bacteriology, but they had an intuition of this double source of infection, and they set themselves to protect their city from it by their marvellously constructed *cloacæ*, which promptly carried all excreta away from inhabited neighbourhoods, and by their equally marvellous aqueducts, which supplied every urban quarter with the purest water in such volume that it kept constantly flushed the *cloacæ* themselves. This hygienic practice they consecrated in their cult of the goddess Cloacina, and they sealed it with the physiological axiom: 'Ubi bonæ sunt aquæ, ibi bonus; ubi malæ, malus itidem est aer.' A part of this precious heritage, the aqueducts, abides with us their effete posterity, and it was precisely this which kept us in the health and strength we enjoyed, in spite of everything we did, by our effeminate lives, led amid corruption and dissipation, to spoil it. It was precisely that portion of the antique, supremely pure, potable water which chanced to remain to us, notably the Acqua Vergine, which maintained Rome up to the other day, even in her Ghetto, free from those terrible typhoid epidemics which in every other city have for centuries raged so fiercely and reaped so many victims." Dr. Fattorini then describes to his readers how the Acqua Marcia reintroduced into Rome in 1870, and distributed to the new quarters in scanty volume, has combined with the English watercloset system to convey the sewage effluvia from floor to floor of the dwelling-houses. Moreover, this Marcia water having lost its great original purity, lies in cisterns on these floors till it loses its initial coolness (12° C.), at which bacteria do not live, and rises in warm weather to 25°, or even 30° C.—a temperature most favourable to all manner of putrid fermentations. Dr. Fattorini urges the ædiles of modern Rome to insist on every house, before it is inhabited, being furnished with the ordinary means of preventing the drinking-water [redacted] with sources of sewage

contamination, and in the meantime recommends all inhabitants of the Marcia-supplied quarters to use that water only in the boiling state for culinary purposes, and to drink nothing but the Acqua Vergine, which feeds the public fountains in such sparkling and exhilarating volume.

THE "CAN" AND THE "SHALL" OF WOMAN-CULTURE.

No physiologist will question the possibility of developing by appropriate stimuli, exercise, and food, any particular part or parts of an organism in such manner as to make it respond to the demands of its environment. Beyond doubt this mode of development is the natural process of evolutionary growth and modification. It must, therefore, be theoretically possible, as it has been abundantly shown to be practicable, that a female of the species *homo* shall be developed in respect to any one or more of her organic potentialities to a level with the male. And what has happened in the case of an individual may occur in any number of instances. In short, the difference between woman and man in respect to any of the brain or muscle functions is, as the difference between any two women or any two men respectively, one of development by training. The female is undoubtedly, from a developmental point of view, an animal in which the evolutionary process has been arrested or, more accurately speaking, diverted from the general to the particular, for special reproductive purposes, before the culminating point could be reached; moreover, it has been maintained that the controlling force as regards the determination of sex is one of procreative ascendency, the temporarily more exigent parent determining sex on the side of desire; the male parent selecting, in an evolutionary sense, female offspring, the female parent selecting or determining males. The explanation of the *modus operandi* of procreative exigency is that this exigency is the effect of preparedness to produce. The point to perceive is that the differentiation of sex is not in the nature of superiority or inferiority as regards the integrity of the animal organism, but one of special fitness, and therefore there are certain *plus* or *minor* qualities connected with sex which are the natural concomitants of the differentiation, but do not constitute disabilities. Thus the female is smaller than the male, unless smallness be an advantage in respect to locomotion, as in certain birds, when the apparent rule is not followed, because the real underlying and constant principle necessitates a change of policy, with the same object and a seemingly different, though actually identical, result. Meanwhile there is no physiological reason why the female should not be developed to proportional size equal with that of the male if suitable stimuli, exercise, and food be applied. We do not doubt that in a certain number of generations, women, if cultured as men are cultured, might be developed in all respects to the same proportions as men in respect to brain or muscle, or both; but we contend that if this were accomplished they would be *monstrous*. A masculine race of women would be as abnormal as an effeminate race of men, and in process of time the instinct of nature would assert itself, so that womanly women would feel the same contempt for masculinity in their sex as manly men feel for effeminacy in theirs; and when this instinct asserted itself, there would commence, involuntarily and uncontrollably, a reversion to the normal type, so in time the monstrosity of development would correct itself; though not, perhaps, until—as often happens in revertings to a lower type—the returns were carried too far, and the female unduly degraded for a time. There is evidence that this has occurred. As regards any individual woman or any number of women not *personally* defective in regard to organic capabilities, it must be conceded that they *can* do anything that a man of similar [illegible] able to do; but the question *shall?* arises; and though we are not prepared to go the length of saying that the special powers of sex will be impaired by the general development, we are of opinion that the rule of natural fitness will be broken, and in the end so disadvantageously that Nature must and will interpose to restore the type by reversion. This we take to be the sum of the argument in explication of the question, "Can a woman do a man's work?" The subject is one which cannot be intelligently studied or discussed apart from the recognition of physiological laws and principles.

OUR INCREASING POPULATION.

HAVING, in his annual report on the parish of St. Mary's, Islington, announced that the death-rate for 1885 was the smallest on record, Dr. Meymott Tidy discusses the meaning of the facts relating to diminishing death-rates as affecting the population of England and Wales. The present population may be set down at 24,000,000, and the acreage of cultivated land at 30,000,000; there being thus one person to 1·25 acres, or about one-fourth the quantity of land per head of the population of Europe as a whole. But statistics show that 150 people are every year added to every 10,000. Reminding his readers that about twenty generations have passed since the Norman Conquest, Dr. Tidy asks what will be the result when twenty more generations of Englishmen are numbered among the dead: and he explains that at the present rate of increase there will then be a population of 27,220,000,000, who would require a place of abode of twenty earths if the then population were no more dense than the present one now is. Tracing the increase in population through its various stages, the report points out that in the reign of Henry VIII. the population of England, kept in check by wars and pestilence, numbered not more than 5,000,000, whilst in the early part of the reign of George III. it was about 7,500,000. Then came a period of commercial prosperity, and with this the population of England went up first to 10,000,000 or 11,000,000, and then to 16,000,000 at the period of the repeal of the Corn Laws. At the present time 24,000,000 have to be housed and fed in England and Wales; and in face of this fact we have to remember that our exports are things that cannot be eaten, whereas 50 per cent. of the food we require comes from abroad. Dr. Tidy doubts the healthy condition of a nation that cannot maintain itself, and he regards the present increasing population and declining trade as serious facts for the sanitarian and sociologist.

MUSCULAR ATROPHIES.

THE most commonly recognised muscular atrophies are those that result from disease of the spinal cord and nerves, as well as that variety which is due to simple disuse. The neuritic and myelitic muscular atrophies are remarkable for the rapid rate of the wasting. That which is the simple outcome of disuse is manifested gradually. The electrical reactions of the wasting muscles are of great interest, and serve to group the different varieties into at least two main classes. Inflammation of the spinal motor cells, or of their prolongations in the mixed spinal nerves, leads to rapid atrophy, and the nerves soon cease to respond and the muscles to contract to the faradaic current. In chronic spinal muscular atrophy, or progressive muscular atrophy, the reaction of the muscle to faradaism is retained so long as any muscular fibres remain. In this disease it would seem as though we had to deal with a degenerative affection of the whole muscular apparatus, for in many cases the whole length of the nerve-cells and fibres of the brain (pyramidal tracts), as well as those of the spino-muscular segment, are found to be wasted. In the amyotrophy resulting from arthritis, about the pathology of which some difference of opinion exists, the electrical reactions are generally

normal, but a change may be detected in some cases. As a general rule the wasting occurs in the entire length of the extensors of the joint affected, though other muscles moving the joint may be wasted, and occasionally the whole of the muscles of the limb are involved. The muscular atrophy that attends arthritis deformans of the multiple type is frequently remarkable. It has been ascribed, with the joint affection, to the influence of abnormal impressions from the generative organs acting on that part of the spinal cord corresponding to the muscular and arthritic atrophy. But it is quite as probable that the muscular wasting is the result of the joint disease, and of the same order as the amyotrophy resulting from an arthritis, however induced. It is supposed that the arthritic muscular atrophy is of reflex origin, due to the disturbance of some trophic nerve centre, irritated by the painful state of the sensitive nerve fibres. In addition to the amyotrophies already mentioned, there is a variety due to over-use; this is most frequently met with in feeble individuals, who use the muscles, generally those of the hands, unduly. But the list of muscular atrophies is not yet exhausted, for we have to recognise the idiopathic forms, of which the pseudo-hypertrophic paralysis is the best known. The simple idiopathic kind, in which the muscles waste gradually, without, so far as is known, any atrophy of the nerves or spinal cord, runs in families, and usually begins before adult life is reached. Some have even endeavoured to make another variety of this idiopathic group by separating those cases in which the atrophy begins in the face. Sometimes the amyotrophy accompanies hysterical paralysis, and cannot be ascribed to simple disuse, for the atrophy is frequently of rapid course in these cases. The same sort of atrophy of muscles is witnessed in the cases of disease of the spinal cord where the lesion does not anatomically affect the parts presiding over the nutrition of the wasting muscles. We must here suppose that some kind of morbid influence is exercised by the coarse disease of possibly the same kind as is transmitted to the trophic centres from diseased joints. The electrical reactions in this last class of cases are also generally normal.

SUFFOCATION IN A WELL.

A PAINFUL story of death from misadventure, which in this as in so many other cases means death from ignorance or carelessness, was investigated the other day by Dr. Danford Thomas. A prisoner in Pentonville Gaol volunteered, with a colleague, to descend a disused well for the purpose of removing pumps. The danger of such a proceeding is manifest, and it is reported that the authorities were warned of the danger, and the jury certainly appended a censure to their verdict. One of the men died and the other was so much affected that he had to go to a hospital. It is scarcely necessary to remind our readers that the utmost caution should be used before entering any well or confined space. Carbonic acid generates under a variety of conditions, and its action, even in small quantity, is not only poisonous but paralysing. The candle test is, when properly used, sufficient. If the candle burns clear and bright to the very bottom there is no danger, but if it does not go to the bottom there is always a possibility that carbonic acid, which is half as heavy again as air, may lie there, as in the celebrated Grotto del Cane, in which a man can stand while a dog is asphyxiated. It is commonly supposed that carbonic acid accumulates only in old or disused wells. This is a dangerous delusion. We were present a few years ago at an inspection of a new well on the estate of our lamented Editor, the late Dr. Wakley. The well had only been sunk a few weeks before in a country place remote from houses. It was loosely covered, and one of the men was about to descend for the purpose of inspection, when Dr. Wakley, with characteristic caution, insisted that a candle should be lowered first. It went out before it had gone six feet; and it is certain that if the man had gone down, as he proposed, he would have fallen lifeless to the bottom. The generation of carbonic acid below the surface of the earth is apparently capricious. The curious pits or caves, some of them more than a hundred feet in depth, which abound in the neighbourhood of Bexley, in Kent, contain no carbonic acid, as we can testify from personal experience, although they are said to have been excavated in prehistoric times; whereas, as in the instance already quoted, the gas may accumulate in a perfectly new chamber. The mere extinction of a flame is not a sufficient indication of danger. If the candle burns dimly there is risk, for the gas acts on living beings as on candles, and insensibility, or exhaustion tantamount to it, may be produced by a quantity of carbonic acid which would not immediately kill.

THE "BONE-SETTER" TRIUMPHANT.

A CASE of considerable importance to the medical profession was decided at the end of last month in the County Court of Cockermouth. The facts were briefly as follows. On June 27th, 1884, a solicitor named Nicholson injured his ankle, and sought the advice of Mr. Spurgin, in practice at Maryport. He remained under his treatment until the 16th of July, when, being dissatisfied with the results, he called in a "bone-setter," who, by the way, was not a duly qualified man. On the part of Mr. Spurgin it was contended that the said injury was only a severe sprain of the ankle, without fracture or dislocation, whereas the bone-setter alleged that the fibula was dislocated, and, further, that he reduced the dislocation. Judgment was given for the defendant (Mr. Nicholson), on the grounds that, according to the testimony of the defendant, "after a somewhat lengthened treatment by the plaintiff his pain and inability to move his foot rather grew worse, but upon the bone-setter operating upon his foot he felt the bone set right and obtained almost instant relief, and was in a short time able to walk as usual." The judge added "could this possibly have happened if the ailment had been a sprain?" He came to the conclusion it could not, and expressed himself "driven to the conclusion that it was dislocation, and not simply a sprain." His honour, with great frankness, gave as his reason for accepting the evidence of the bone-setter in preference to that of Mr. Spurgin and his assistant, that "there have been hundreds of cases where certified professional men have failed to discover the nature and cause of ailments in which uncertified men, or what are denominated 'quacks,' have succeeded in effecting cures." We cannot but think that the argument on this point was unsound, for to make the conclusion valid it ought to have been shown that uncertified men are more often right in their diagnosis and treatment than are duly qualified practitioners. But, apart from this, we maintain it is impolitic to set a greater value upon the alleged experience of a bone-setter than upon the opinion of a properly educated and legally qualified medical man. Having decided that the ankle was dislocated, his honour continued, "I have abundant authority for saying that any surgeon with a moderate knowledge of anatomy ought and might have discovered it." It is a pity Mr. Spurgin did not call medical evidence as to the probable nature of the accident, but doubtless he never dreamed of the judge discarding his professional opinion in favour of that of an unqualified man. We have not the slightest hesitation in saying the judgment was not warranted by the published facts of the case, whatever it may have been by the facts before the court. It is beyond all question that there never was a dislocation of the ankle in this case. The evidence of the defendant Mr. Nicholson, as well as that of the bone-setter, conclusively prove this; for had there been a dislocation, it is quite clear the foot would have crippled too much

to allow of the patient walking in so short time as a week after the reduction of the dislocation. This is one of those cases which Sir James Paget, in an admirable clinical lecture, speaks of as "cases which bone-setters cure." The improvement that followed the manipulation by the bone-setter was clearly due to the rupture of an adhesion consequent on the inflammation and forced rest of the foot incidental to the sprain. From the report of the trial, we cannot find one single fact to show that Mr. Spurgin did not recognise the true nature of the case and treat it with sound judgment and skill. Every surgeon knows that a sprained joint needs rest, and equally that it may be necessary, in order to complete the cure, to use some force at a later period with a view to freeing the joint from impediments which restrict its movements. We commend these remarks to the consideration of the judge who tried the case, for we feel fully convinced that, had he been instructed in the natural history of a severe sprain of the ankle and its appropriate treatment, he would have found abundant proof that there had been no dislocation of the joint. Should his honour ever have the misfortune to meet with a similar mishap as Mr. Nicholson, we ask him to believe (and to act on the belief) that a legally qualified surgeon is more competent to treat a *surgical* injury than a "bone-setter," even though the latter be gifted with hereditary talent unto the fourth generation.

FATAL RESULT OF PEROXIDE OF HYDROGEN INJECTIONS.

A NORWEGIAN surgeon, Dr. Laache, has reported a case in which a fatal result followed an injection of peroxide of hydrogen into the pleural cavity. The patient was a man twenty-eight years of age, who had had a portion of the ninth and tenth ribs resected for empyema. The operation had been successful and the wound progressed favourably, and two months after the operation there remained only a fistula about an inch and a half long. In order to hasten the healing of this, hypodermic injections of a 3 per cent. solution of peroxide of hydrogen were resorted to, as this method of treatment had given very satisfactory results in two somewhat similar cases in which it had been tried. Six injections, each containing 0·8 cubic centimetre of the solution, were administered without any particular effect. At the seventh, however, the patient complained of pain and faintness, the pulse failed, the respiration became oppressed, clonic contractions occurred in the right arm, the head turned to the left, the jaws became tightly set, the face became cyanotic, and the patient died in ten minutes. The necropsy, which was not made till forty-eight hours after death, revealed nothing very striking. The heart was dilated, and contained liquid blood without air bubbles; some ecchymoses were found in the parts of the left lung, which were adherent to the chest walls. In the fourth ventricle of the brain an ecchymosis the size of a pin's head was seen. A number of air bubbles were present in the blood of the hepatic veins, and some were seen on cutting into the spleen and kidneys. The cause of death was therefore by no means clear. Dr. Laache suggests that it may have been the small extravasation in the fourth ventricle or shock. Dr. Wulfsberg, who took part in the discussion on the case at the Christiania Medical Society, thought it was probably due to the introduction of the drug into the circulation. He thought that the strength of the blood current might have carried the peroxide, if introduced into a vein, through the right heart and lungs almost unchanged, but that afterwards more oxygen might have been disengaged than the blood could absorb, and bubbles were thus produced, which may have been the immediate cause of death. Where animals have been subjected to injections of air into the veins bubbles are not always [illegible]. In these cases Dr. Wulfsberg thinks that death has been due to paralysis of the heart, for when examinations have been made immediately after death bubbles have been found in the coronary arteries. As so long a time had elapsed before the necropsy in Dr. Laache's case, these might have been absorbed.

THE TRAGEDY AT FINSBURY PARK.

ON the 20th ult., an inquest was held by Dr. Danford Thomas concerning the deaths of Henry George Underwood, aged fifty-seven, and Jane Underwood, his wife, aged fifty-four. From the evidence it appeared that on Sept. 16th the son of deceased, on returning home late in the evening found the body of his mother lying on the back in her bedroom in an almost naked condition. Expecting his father to come in shortly, he went to bed; but in the morning, finding that his father was not about, and the body of his mother in the position in which he left it overnight, he raised an alarm. On a search being made, Mr. Underwood was found dead in the watercloset, with his throat cut. A razor was grasped in his hand, and the door was fastened on the inside; so there could be no doubt that he had taken his own life. In his case a verdict of suicide during a fit of temporary insanity was returned. It was naturally suggested that he had first killed his wife and immediately afterwards cut his own throat, the supposed motive being an insane impulse caused by his depressed state of mind consequent on the long-continued drunken habits of his wife. The body of Mrs. Underwood was covered with bruises of different ages. Round the neck a silk handkerchief was found loosely tied. On the front of the neck were some marks which might have been produced by an attempt at strangulation; and on the neck, face, and ears were a number of recent abrasions. The lungs were congested, but not particularly engorged. The liver was cirrhotic, and the stomach contained "a quantity of port wine." The deceased was intoxicated in the morning of the day on which she was found dead; after that she was not seen alive. There being some doubt as to the interpretation to be put on the evidence concerning the marks of injury, the inquest was adjourned, and a second necropsy was ordered to be made by an expert pathologist. At the adjourned inquiry on the 27th ult. Mr. Pepper stated that in his opinion the marks on the neck, face, and ears were scratches made by deceased in attempting to free herself from the constricting force applied to the neck. There were three bands of congested skin on the front of the neck, tapering away at the sides, and over them the skin was slightly excoriated. On the right side of the neck and at the nape were two recent bruises. The trachea and windpipe were deeply congested. On the right of the umbilicus was a bruise the size of the palm of the hand, which at the first examination was observed to be purple, but which a few days later had become bright-red in the centre. The bruise was a recent one, and the change in colour was evidently due to the oxidation of the colouring matter of the blood, as this had become diffused in the substance of the skin. Two or three coils of intestine underlying this bruise were deeply congested, but they presented no signs of constriction, ulceration, or rupture, and it appeared certain that the same injury had bruised both the abdominal wall and the bowel. As to the exact sequence of events preceding death it was impossible to speak with certainty, but in all probability the woman was strangled whilst in a helpless state of intoxication, and possibly after she had received a blow in the abdomen, either by falling heavily on some solid body, or at the hands of another person. That no great violence was employed to effect strangulation was proved by the comparative slightness of the marks made by the constricting force, especially as the state of nutrition of the tissues was such as to favour the easy

development of bruises. The jury returned a verdict that deceased died from asphyxia caused by constriction of the neck whilst in a state of deep intoxication, but that there was not sufficient evidence to show by what means the strangulation was effected.

SCARLET FEVER AT NEWQUAY.

THE correspondence in *The Times* on scarlet fever at Newquay has been continued during the past week, and has sufficed to show that the prevalence of this malady was probably in the first instance due to milk infection, and was continued through the suppression of information by lodging-house keepers and others. *The Times* has certainly taught these persons a lesson that their own interests are not best served by such conduct, and if the same powerful voice still continues to give publicity to similar occurrences, lodging-house keepers will find that their own interests are absolutely dependent upon the measures they adopt for ensuring the welfare of those whom they receive, and will be forced to have more regard for the safety of those who visit summer resorts. A system of notification of infectious diseases faithfully carried out is the chief step which must be taken, but more good would come if those who provide lodging accommodation would voluntarily agree to a register being kept at the office of the sanitary authority, which could be consulted by visitors, and give all necessary information as to the sanitary condition of such houses, and as to their freedom from infection. Doubtless, concealment is due to the fear of losing profits which would otherwise be made during the season, and it is therefore necessary that there should be some provision for reducing this loss; this could best be done by the organisation of a system of insurance which would guarantee the payment to the letter of lodgings of some sum as compensation for loss incurred through the house remaining unoccupied on account of the occurrence of infectious disease within it. Such an organisation might also assist in checking the importation of infectious persons. "Medical Officer of Health," in a letter which forms part of the correspondence to which we have referred, writing on the scope and intention of the 90th section of the Public Health Act, 1875, says that this clause applies to houses of the artisans and labourers' class. It is true that this limitation exists as a matter of practice, but there appears to be no reason why these regulations should not be made to apply to houses of all classes which are thus let; the limitation hitherto observed has been due to the belief that they were not required for any but those occupied by artisans and labourers.

THE EASTERN GIPSY 'CRUX."

AN amusing illustration of the difficulties of self-government is afforded by the dead-lock to which matters have come in connexion with the Eastern—it is absurd to call them *Greek*—gipsies, who, having been landed in this country, can neither be got rid of, nor, as it would seem, reduced to the condition of a tolerable integer in the sum total of the population. An autocratic government would simply have shipped them to some other shore and landed them either by stealth or defiantly. Under our milder system of self-rule, we are struggling with the difficulty of solving the question what to do with these children of Esau. The serio-comic element of the situation comes out strongly in a charming succession of incidents. The local police stop them while travelling, and finally direct them to a place of encampment on certain land, the owner's permission being either asked by, or volunteered to, the chief constable. After a while the medical officer of health strives to enforce sanitary provision, and, failing in his laudable endeavours, reports the existence of a nuisance. Whereupon the owner of the property is to be indicted for a nuisance! Could anything be more absurd than this business throughout? It doubtless seems perfectly proper to the authorities concerned. Their sole concern is to get rid of the nuisance. It was even suggested that some benevolent person should provide a cart, and these gipsies could then "move on" on the Queen's highway, where no one would stop them. A vagrant band has no special interest for local sanitary authorities, provided only that it keeps moving. Thus it is that public health is reduced to the position of a football which may be kicked about at pleasure, and the only aim of the players is to keep it out of their bounds, where else it may go being a matter of perfect indifference. The aim of the medical officer to establish sanitary conditions in this case was frustrated at the outset by the mere objection of the owner of the property to allow the erection of even movable closets!

DRESS OF SOLDIERS ON FIELD SERVICE.

COLONEL TULLOCH, in a recent number of the *Illustrated Naval and Military Magazine*, has given a description of an extemporised dress which was adopted in the battalion of the Welsh Regiment under his command in South Africa, in anticipation of being sent on field service. The clothing of the men was the same as in England, and was ill suited for active service during the hot season in Natal; the colour of the scarlet kersey was also considered to be objectionable, and there was not time to obtain suitable light clothing from England or khakee from India. An additional stout grey flannel shirt was therefore issued to each man, to be worn as a blouse over his other shirt instead of the kersey. Shoulder straps of cord were put on to retain the belts in position. This dress had the advantage of being loose about the neck and throat, cooler than that which it replaced, and of a less conspicuous colour. It seems to be remarkably well suited for the purpose for which it was devised, and would doubtless have added materially to the comfort of the men in the field. Colonel Tulloch also suggests the removal of the metal ornaments from the helmets, or, still better, the substitution of a pith helmet for that now in use. These were worn by the "Royals" at Hong-Kong and on field service in China twenty-five years ago, and have the great merits of being light, cool, and inexpensive. Colonel Tulloch's experiment might prove practically suggestive to those in authority who are responsible for the clothing of the soldier.

SUFFOCATION; MUSSEL POISONING; HEART DISEASE; SYNCOPE?

THE evidence tendered before the coroner at Westgate, Rotherham, on Sept. 28th, concerning the death of a labourer named John Sykes, aged thirty-six years, was consistent with death having occurred from one or more of the causes mentioned at the heading of this note. Deceased had "rheumatic fever" three or four years ago, but whether it left any cardiac mischief was not known. On the day before his death he got drunk and vomited. He was put to bed in the evening, and at half-past four in the morning he was found dead. It seems not improbable that vomiting occurred whilst deceased was in a state of partial consciousness, and that he was suffocated by some of the vomited matter getting impacted in the air passages. Or the exhaustion consequent on persistent vomiting in a person of weak bodily powers may have terminated in a fatal fit of syncope. Or, again, there may have been cardiac valvular disease, and the strain on the heart incidental to vomiting may, together with this, have determined the issue. We do not attach much value to the fact that he had been [illegible] for no one else seems

to have suffered any ill effects from this possible source. Lastly, death may have ensued from acute alcoholic poisoning. The coroner left it to the jury to say whether it was desirable to have a post-mortem examination made, but "the good men and true" were satisfied, and returned a verdict to the effect "that death took place from natural causes, probably from heart-disease"—a most unsatisfactory ending to the inquiry, as we think. If, as seems likely from the evidence, deceased was so intoxicated as to necessitate his being carried home, someone ought to be made answerable for having supplied him with a poisonous quantity of alcohol, or with having served him with more "drink" when he was already inebriated. It is true the matter was one for the jury to decide, but a little persuasion and guidance on the part of the coroner generally suffices to induce them to be led in the desired direction; and in this case, we think, the inquiry should have been adjourned for further medical evidence—viz., that which could only be obtained by a necropsy.

THE DIRECT REPRESENTATIVE FOR IRELAND.

DR. KIDD'S candidature has been pressed forward by a large meeting of the profession at the Shelbourne Hotel on the 29th ult. Resolutions were proposed by Drs. Gordon, Aquilla Smith, and R. McDonnell, the chair having been filled by Sir George Porter. The Executive Committee consists of Drs. Bennett, Corley, Gordon, Mapother, and Wm. Stoker. The only objection to Dr. Kidd is that he is not a general practitioner; that Dublin and its corporations are already amply represented. If the new seat is to go to a dignitary of one of the colleges, it might as well not have been granted. It rests with the practitioners of Ireland to show that they are capable of promoting successfully the election of one of their own number.

"FOUND DROWNED."

NOT long since the body of a young woman named Elsie Corfe, of highly respectable position and family, was found drowned in the river at Bath. There was no evidence to show how deceased got into the water, or how her death was occasioned. On the evening before her body was discovered in the early morning, she appeared in good health and spirits, and there was utter absence of known motive to commit suicide. The fatality has caused considerable excitement in the neighbourhood, where deceased was well known and respected. We cannot help thinking that it would have been a wise procedure on the part of the coroner's court if a post-mortem examination had been ordered. The cause of death would then have been elicited, whereas the case now stands—"a mystery"—just as the jury received and dismissed it.

DR. VON HOLST ON NITRO-GLYCERINE.

DR. L. V. HOLST reports in a St. Petersburg journal a number of observations on the action of nitro-glycerine on heart diseases. He considers that it is especially useful where little or no serious organic change in the heart muscle or valves has taken place, and where the affection is mainly due to a debilitated condition of the organ. In angina pectoris Dr. von Holst has found nitro-glycerine very useful; in one case, indeed, it produced a permanent cure. He recommends recourse to this drug instead of to camphor and musk in cases where great cardiac weakness threatens immediate danger to life. He considers that the diuretic action is not due to any direct stimulation of the kidneys, but is a consequence of the regulation of the heart's action. He finds that dropsy, if due to heart weakness, diminishes under the use of nitro-glycerine, but that it [illegible] influenced by it. With regard to the dose, the author advises that small quantities should be given at first, and increased gradually according to the effect on the particular case. The preparation he uses is a 1 per cent. alcoholic solution, and of this he gives from one to six drops three times a day.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.

AT the annual general meeting of the Faculty on Monday last, Dr. James Morton, Professor of Materia Medica in Anderson's College, was elected president. Dr. Morton has fairly earned the compliment thus paid him, and the dignity and interests of the Faculty will be safe in his hands. A special meeting was held at the close of the annual meeting, for the purpose of disposing of the case of the "Erring Fellow," whose name is associated with a much-advertised liniment. The Fellow in question was suspended from the Fellowship for a period of six months, as, notwithstanding the facts that he had professed submission to the will of the Faculty, acknowledged his error and made an abject apology, and had also promised to withdraw from all connexion with the liniment by Sept. 1st, the preparation was still advertised and purchasable at the time of the meeting of the Faculty. The Faculty deserves credit for the manner in which it has dealt with this case, for, while it acted with energy, it gave every opportunity to the offender to withdraw from his unfortunate position, and proceeded to extreme measures only when it was seen that the dignity of the profession, as represented by the Faculty, could be maintained in no other way.

THE JUBILEE OF HARVARD UNIVERSITY.

ON the 7th of November next, the Harvard University of Cambridge, Massachusetts, will have completed its 250th year, and it is proposed to celebrate the event in a suitable manner from the 6th to the 8th of that month. The University was established by an Act of the Colonial Legislature, and a certain John Harvard so liberally endowed it that it was decided to give the new institution his name. The jubilee will have great interest to the members of the medical profession, for this University has taken a leading part in the education of medical men for the Eastern States of America; and it has particularly distinguished itself by its persistent efforts to raise the standard of medical education. Its medical degrees have been very highly valued, and all friends of higher medical education will rejoice to know that age has in no way impaired the usefulness or the vigour of the University. With one exception, Harvard is the oldest university in the New World. Nearly 100 years before, in 1551, the Emperor, Charles V., established the University of St. Mark's at Lima.

BLIGHT ON AUTUMN AND WINTER GREENS.

THE value of green vegetables as an article of diet was recognised a century and a half ago by Arbuthnot, physician to Queen Anne, who in a treatise "On the Nature and Choice of Aliment," which was published in 1732, writes that "of alimentary leaves, the *potherbs* afford an excellent nourishment; amongst these are the cale or cabbage kind." Few things add to the relish of the poor man's dinner more than an abundance of well-cooked cabbage. "Bacon and greens" are proverbially popular. The old and general idea that green vegetables act beneficially in counteracting a disposition to what are popularly known as scorbutic affections is confirmed by modern experience. Thus any lessening of the supply or deterioration in quality of winter vegetables of the cabbage tribe is a subject of regret both to poor and well-to-do persons. The present autumn has been very favourable to the development of the species of blight

or aphis which attacks the cabbage tribe in particular. These diminutive insects prey upon the plants and so stunt their growth that gardeners are much concerned about their autumn and winter vegetables. In spring the aphis commits great havoc among young cereal plants, but in autumn, which is a period of active propagation, it attacks chiefly garden vegetables. It is a curious fact in natural history that the aphis propagates after fecundation for eight or nine generations without intermediate fecundation. "L'influence d'une prémière fécondation s'étend ainsi sur plusieurs générations successives." So writes a French naturalist; and it is calculated that a single mother may be the means of producing five thousand million offspring in the course of a few generations of ephemeral existence. These numbers account for the havoc such diminutive creatures can cause.

THE RETIREMENT OF SIR HENRY ROSCOE.

THE Victoria University, formerly Owens College, Manchester, sustains a great misfortune in the resignation of Sir Henry Roscoe. For many years Sir Henry has been recognised all over the civilised world as one of the greatest scientific men of our age. His researches have added chapters to the history of chemistry, his writings have adorned it, and his teaching has equipped a host of brilliant and useful scientific workers and successful teachers. His uniform courtesy, and the ready help he has afforded to all who sought it, have procured him high esteem among men, and when he was elected to a seat in Parliament all lovers of science rejoiced. The great empire of science is but imperfectly represented in England, and all felt that in Roscoe it had gained a worthy supporter. It is no doubt the pressure of Parliamentary duties which has led to the loss with which the Victoria University is threatened. We say threatened, because we are inclined to hope that even at the last moment Sir Henry Roscoe may be induced to reconsider his determination. Of course his Parliamentary duties would diminish considerably the time he could devote to the work of personal teaching in Manchester, but he could still deliver the most important part of the course of lectures, and his great reputation and experience and his power of organisation would still be at the service of the young University. The details of teaching could easily be carried out by others, but no one can replace Roscoe as a head. Doubtless the University authorities see all this as plainly as we do, and will do their utmost to prevent their most distinguished ornament from leaving them.

RELATION OF MEDICAL MEN TO DENTAL QUACKERY.

WE have had a matter of professional etiquette referred to us lately. A medical man writes saying that he was called in upon two occasions to administer chloroform to patients by a man who practises dentistry, but who, he has since been informed, is not registered, and our correspondent wishes to know what course he should pursue in future. There can be only one possible answer. He should absolutely refuse to attend. To associate in any way with one who is liable to prosecution, should he ever call himself a dentist and yet practises, must bring discredit not only upon himself but upon the medical profession generally. We will go further and say that no medical man should allow his name to be connected in any way with dental quackery or advertisement. Dental specialists have for years worked hard, and with success, to raise their professional and social status, and they look to their parent—the medical profession—to help them by not encouraging irregular dental practitioners.

ROYAL UNIVERSITY OF IRELAND.

BY the death of the Rev. J. Kavanagh, who was accidentally killed last Monday, another vacancy on the Senate of the Royal University has arisen. The deceased met his death in a singular manner. While performing service in the chapel a statue on the canopy of the altar, weighing about 40 lb., fell, striking the unfortunate clergyman, and precipitating him with considerable violence to the ground. This caused a fracture of the skull, and an injury to one of the branches of the temporal artery, which caused death in less than an hour. It is probable that to the names already mentioned as candidates for a seat on the Senate may now be added that of Dr. Knight, who may be induced to come forward.

TREATMENT OF TUBERCULAR MENINGITIS.

THE *Revue de Thérapeutique*, after stating that tubercular meningitis kills 25,000 persons every year in France alone, and quoting a passage from Jaccoud, in which he speaks of the powerlessness of medical men to cope with this terrible disease, cites some recent observations of a Swedish physician, M. Warfwinge, on the marvellous effects of a 1 to 5 iodoform ointment rubbed into the previously shaved head in quantities of seventy-five grains, night and morning. During the interval, the head was covered with an oilskin cap, which was secured by a bandage. M. Warfwinge treated five cases in this way, with a successful result in every case. The first case was treated for seventeen days, the second for nineteen, the third for thirty, the fourth for thirty-two, and the fifth for nine days only. Ordinary remedies were given in addition for any complications which arose, but M. Warfwinge attributes the successful results to the iodoform alone.

A STEP IN THE RIGHT DIRECTION.

OUR correspondent in Rome writes:—"The Hygienico-sanitary Commission has sent in its report to the Minister of the Interior, and that functionary has accordingly issued a circular to all the Italian communes, requesting them to furnish him with scientifically ascertained particulars of their water-supply, which the aforesaid commission had animadverted on as being bad, suspected, or insufficient. This step, he says, is taken with a view to providing every commune throughout the peninsula with sound potable water, and to invoking, if necessary, the authority of Parliament *ad hoc*. Such announcements are reassuring as to the public health of Italy, especially if taken in connexion with her fast-waning belief in quarantine by sea as well as by land."

ARMY MEDICAL SCHOOL.

THE winter session of the Army Medical School was opened on Friday, the 1st inst., when the introductory address was delivered by Surgeon-General Sir T. Longmore, C.B., Professor of Military Surgery. There were sixty-six surgeons on probation present, forty-one being candidates for commissions in the British Medical Service and twenty-five in the Indian Medical Service.

LOCAL AUTHORITIES.

MR. T. HARNESS HARRISON appears to have read at the Congress of the Sanitary Institute a paper which condemns, in terms not of the mildest, the motives and actions of members of local authorities. While expressing the opinion that the Public Health Acts are fairly satisfactory measures, he says that the bodies who administer them consist largely of men whose object is to frustrate their operation—these members, together with those who are passive, making 95½ per cent. of the to[redacted] do not doubt that this

estimate may be true for certain authorities. There are some who have earned an unenviable notoriety for their opposition to sanitary measures and their treatment of officials whose duty it is to carry the law into effect; but the progress the country has made during the present century, the large sums of money spent in public sanitary works of water-supply and drainage, are themselves evidence that local authorities as a whole are not backward in their duty. More harm than good is done by neglecting to recognise the benefits many districts have received at the hands of local representatives; condemnation should be reserved for those who are alone to blame.

MORE CANDIDATES FOR DIRECT REPRESENTATION IN ENGLAND.

MR. JOHN PAGE HENTSCH writes us to say that the members of the Medical Alliance Association and others have invited Mr. R. H. S. Carpenter and Mr. George Brown to stand as candidates for the Direct Representation seats in the General Medical Council, on the ground of the services of these gentlemen in connexion with attempts to prosecute illegal practice. Both of them have accepted the invitation. Whoever be the candidates returned, it will be their duty to use the powers of the Council and of the Act to the utmost in discouraging and punishing illegal practice.

THE SANITARY ASSOCIATION OF SCOTLAND.

THE twelfth annual meeting of this Association was held last week at Paisley, under the presidency of Mr. William Mackison, C.E. Two excellent papers were read by sanitary inspectors. "The Higher Aspects of Sanitation" were discussed by Mr. George A. D. Mackay, who gave some interesting statistics of the proportion of the total number of families living in one room in eight Scotch towns; while Mr. George McKay contributed a paper on "Ancient and Modern Sanitation," and showed in a tabular form the percentage of improvement in the death-rates in different districts in Scotland, and concluded with a number of suggestions, having as their object the promotion of sanitary work. The published accounts of the meeting appear fully to justify the statement of the chairman, that never was there a time when so much was being done to remedy existing sanitary defects as at present.

DENTAL CARIES IN BAKERS.

PROF. DR. HESSE of Leipsic, in the *Deutsche Monatschrift*, points out the deplorable condition of the teeth of bakers, and says that he is often able to tell the profession of the patients by the condition of their teeth. The caries is soft and rapidly progressive. The principal parts attacked are the labial and buccal surfaces of the teeth, commencing at the cervix and rapidly extending to the grinding surface. The approximal surfaces do not seem to be attacked more than in other patients. He believes the disease to be due to the inhalation of flour-dust, the caries being caused by the action of an acid which is formed in the presence of fermentable carbohydrates.

CARE AND EDUCATION OF IDIOTS.

AT the congress of those in charge of idiots held last month in Frankfort, Dr. Wulff, director of the asylum at Langenhagen, spoke strongly of the great importance of good nourishment for the inmates of such institutions, the meals, which should if possible number five daily, requiring skilled supervision, and the idiots being attended to by intelligent and careful persons. Dr. Berkhan, of Brunswick, spoke on Cretinism, and demonstrated the points of resemblance of a cretin's scull to those of microcephalic subjects and Aztecs. He dwelt upon the diminution in cretinism which had already been produced by better attention to the nourishment of children in their earlier months and improvements in their surroundings. Dr. Barthold, director of the M.-Gladbach Asylum, read a paper on the Education of Idiots, showing how the doctor and the schoolmaster must work hand in hand. Suggestions were also made for forming classes for children of weak intellect in large towns; and Dr. Sengelmann, of Alsterdorf, read a paper on the Training of Teachers and Attendants for Idiots It was decided that the next place of meeting should be Brunswick.

TUBERCULAR ULCERATION OF THE VULVA AND VAGINA.

THE current number of the *Viertel. für Dermatologie und Syph.* contains a paper on a rare case of extensive ulceration of the vulva and vagina, by Dr. H. Chiari. A lithographed plate shows the extent and shape of the ulceration in the parts as removed from the patient, aged thirty Most of the internal organs of the body were the seat of chronic tubercle—lungs, bronchial and mesenteric glands, intestines, left suprarenal body, cerebral meninges, liver, spleen, and kidneys. The manner in which the infection of the vulva was effected is discussed, and the suggestion made that the germs from the intestinal disease may have been accidentally inoculated on the site affected. It should be stated that the uterus and its appendages were free from disease, and that the patient was a nullipara.

THE CHOLERA IN EUROPE.

THE cholera is steadily diminishing in Italy, and intelligence as to fatal attacks is almost entirely limited to the south of the kingdom. The disease still clings to the Bay of Naples, although it is much less severe than formerly. In the Austro-Hungarian Empire some fresh places have been attacked, and the malady is still fatally prevalent at Trieste and Pesth. In Pesth the fatality is now reduced to about four a day; and Szegedin, where twenty-eight cases and eleven deaths occurred in the forty-eight hours ending the 5th inst., is the only place where the disease shows any important increase. There are serious accounts of the ravages committed by cholera in Seoul, Corea.

MANSION HOUSE CHARITIES.

THE Hospital Sunday Fund has now reached a total of £40,000, and there are still fifty-four collections from churches and chapels to come in. Adding this to £78,0000 subscribed for the unemployed poor of London, nearly £120,000 has been raised for strictly metropolitan purposes, not to mention £6500 raised for the relief of the sufferers of the appalling earthquakes of Charleston and Greece. The Mansion House authorities must be congratulated on such results, especially when the badness of the times is considered.

FOREIGN PROFESSORIAL APPOINTMENTS.

THE following *agrégés* have been appointed for eight years to lecture on their respective subjects in the different Faculties of Medicine in France:—*Paris:* MM. Quenu and Poirier, Anatomy and Physiology. *Bordeaux:* M. Ferré, Anatomy and Physiology; M. Nabias, Natural History. *Lille:* M. Assaky, Anatomy and Physiology; M. Barrois, Natural History. *Lyons:* MM. Rodet and Jaboulay, Anatomy and Physiology. *Montpellier:* MM. Gilis and Tapis, Anatomy and Physiology. *Nancy:* MM. Benè and Nicolas, Anatomy and Physiology.

Buda-Pesth.—Drs. Israi and Bakó have qualified as privat-

locents for Laryngology and Diseases of Urinary Organs respectively.

Prague (Bohemian Faculty).—Dr. Joseph Thomaier has been appointed Extraordinary Professor of Special Pathology and Therapeutics.

St. Petersburg.—Dr. A. Pöhl has been granted the title of Honorary Professor of Medical Chemistry in the Princess Helena Paulovna Clinical Institute.

Würzburg.—The names of Professors Schörnborn, Trendelenburg, and Miculicz are those selected for the vacant Professorship of Surgery.

AT a recent meeting of the Glasgow Town Council an account was given of an outbreak of scarlet fever which is likely to promote the adoption of measures for the notification of cases of infectious disease. Scarlet fever has, it appears, attacked a number of persons receiving milk from a particular dairy, forty-four cases occurring among the milk consumers. A child suffering from this disease was found at the dairy, but the parents refused to permit its removal to hospital because their own medical man had declined to certify to it. For the protection of the public the dairy was closed, the premises fumigated, and the milk found upon them destroyed.

IT will be seen from our advertisement columns that the inaugural dinner of the Glasgow University Club, London, will take place at the Holborn Restaurant on October 22nd, at 7 P.M. The hon. secretaries are Dr. Heron, 57, Harley-street, W., and Mr. McIlraith, 3, Furnival's-inn, E.C., of whom tickets may be had.

AT the Westminster Hospital, Mr. Arthur Marmaduke Sheild, M.B., F.R.C.S., has been appointed assistant-surgeon, in place of Mr. Boyce Barrow, who has resigned; and Mr. James Black, F.R.C.S., has been appointed aural surgeon.

THE MEDICAL ACT, 1886: FOREIGN AND COLONIAL PRACTITIONERS.

BY A BARRISTER-AT-LAW.

THE Medical Act of the present year restricts the right of practising in the colonies which our registered practitioners have hitherto possessed; and it prescribes terms upon which both colonial and foreign practitioners may be admitted to registration in the United Kingdom.

Under the Medical Act of 1858 (Section 31) a registered practitioner had the right to practise, according to his qualification, and to recover his fees in any part of Her Majesty's dominions. A subsequent Act (the Medical Act of 1868, Section 3) enabled every colonial legislature to require such practitioner to register, as a condition of practising, within its jurisdiction; but it left him entitled to registration upon payment of the proper fee, and therefore (though in the requirement of a fee there may have lurked some possibility of obstruction) it left his right to practise unimpaired. In future, however (from June, 1887), though all existing rights of individuals are reserved, the right of our registered practitioners to practise in the British possessions is made "subject to any local law" (the Medical Act, 1886, Sections 6 and 25); it will exist wherever, in the British empire, and so long as, there is no local law regarding it; but every local legislature may impose conditions upon it, and may even, if so disposed, exclude it altogether.

In this, no doubt, a concession—a large one, too—has been made to colonial practitioners at the expense of practitioners registered in the United Kingdom. To deter them from pressing for an illiberal use of it, there are the conditions upon which they in their turn, and foreign practitioners also, are by the recent Act enabled to claim registration in the United Kingdom. Broadly speaking, this Act provides for a sort of reciprocity, as regards the right to practise and recover fees, between the United Kingdom on the one hand, and foreign countries and British possessions on the other.

The decision to admit any colony or foreign country to the benefit of the Act will be made by the Queen in Council, but this will be preceded, no doubt, by communications or negotiations, and probably by some more or less formal compact, between the colony or foreign country and our Colonial or Foreign Office. And any British possession or foreign country may, by order in Council, be declared to be a British possession or foreign country to which the Act will apply (from a day named in the order), if it affords to the registered medical practitioners of the United Kingdom "such privileges of practising as to Her Majesty seem just." (Section 17.) Till this is done for a colony or foreign country no right will accrue to any practitioner holding its qualifications. And this done, it will fall to the Medical Council to decide what degrees or diplomas, or combinations of degrees or diplomas, granted by the colony or foreign country can be recognised as furnishing a sufficient guarantee for the knowledge and skill required in the efficient practice of medicine, surgery, and midwifery. It should be said, however, that where, in working the Act, qualifications which have not been thus recognised are tendered to the Medical Council and rejected by it, the claimant of registration may appeal to the Privy Council, and that the Privy Council may order his qualifications to be recognised. (Sec. 13—1, 2.)

The provision that may so be made in favour of any colony or foreign country may be revoked by subsequent order in Council, and may thereafter be renewed. Rights acquired under an order will not be prejudiced by its revocation; but on its revocation the country affected will fall out of the list of countries to which the Act applies, so that no further claim to registration can be received from persons holding its diplomas or degrees.

The Act provides (Section 14) that the Medical Register shall in future contain a list of colonial practitioners and a list of foreign practitioners, and it allows those who are so entitled to be registered in both lists. For the phrase "colonial practitioner" does not in the Act mean a practitioner of colonial birth, but a person, wherever born, who holds colonial diplomas, granted in a colony to which the Act has been made applicable, and recognised by the General Council; who is by law entitled to practise medicine, surgery, and midwifery in the country which gave him his qualification; and who, moreover, fulfils certain other conditions. And, similarly, the phrase "foreign practitioner" extends to all persons, wherever born, who hold recognised foreign diplomas, granted in a country to which the Act applies, who are by law entitled to practise as aforesaid in the country which granted them, and who fulfil certain prescribed conditions. An applicant for registration in either list must prove his qualification and right to practise as above mentioned, and also that he is of good character, to the satisfaction of the Registrar of the General Council. Thereafter, the "colonial" applicant must prove, to the satisfaction of the same functionary, that he obtained his qualification either (1) at a time when he was not *domiciled* in the United Kingdom, or (2) in course of a continuous absence from the United Kingdom lasting for not less than five years (these are the continuing and more important provisions); or (a transitory provision) that when the Act became applicable to the country from which his qualification is derived he was practising medicine and surgery (or a branch of either) in the United Kingdom, and that he had been so practising, in the United Kingdom or elsewhere, continuously for ten years preceding at least (Section 11). The "foreign" applicant, if he is a British subject, whether a native of the United Kingdom or a colonist, is under precisely the same conditions. If he is not a British subject, proof of that fact suffices for him (Section 12). Registration in either list, where a claim to it has been established, will be granted, without examination, on payment of a fee, not exceeding £5, to be fixed by the General Council. That there may be an appeal to the Privy Council as regards the qualification tendered has already been mentioned. There may be an appeal, also, when registration is refused on any other ground (on a question of character, for example, or on a question of domicile), and the Privy Council may overrule the decision of the Registrar.

Of the transitory provision for the case of persons practising in the United Kingdom when an order in Council comes into force, and having qualifications recognisable under the order, all [illegible] be said is that while, on

the one hand, there will be no inquiry as to the circumstances in which they obtained their qualifications, they must, on the other hand, have been at the date referred to in practice continuously for not less than ten years. The meaning of the proviso is plain enough, and it is with that only that this article is concerned. As to the continuing provisions, a foreigner of good character claiming on a sufficient foreign qualification will always have an easy task, having merely to prove that he is not a British subject. In other cases the question of domicile may now and then raise a difficulty. The word "domiciled" is of course used in the Act in its technical meaning; and (though that is not to be explained briefly) it seems necessary to say that, in the legal sense, one may be domiciled in England though not a resident in it, or a resident in England without being domiciled in it. A man's domicile is, to begin, in the country of his origin, and mere absence from that country, however prolonged, will leave his domicile still there; for a change of domicile, he must be absent without thought of returning, and resolved to spend his life in some other country in which he is settled. It is needless, however, to forecast the questions of domicile that may arise. Here it is enough to say that, in general, a person born and bred in the United Kingdom will, as being domiciled in the United Kingdom, be unable to claim registration on either a colonial or a foreign qualification, unless he got it in course of a continuous absence from the United Kingdom of not less than five years; and that, in general, both a foreigner and a colonist (as to whose domicile there will usually be no room for doubt) will have no difficulty in claiming on either.

Provision is made (Section 15) for the entry in the Register of the qualifications possessed by persons registered as colonial or foreign practitioners. Provision is made also (Section 16 another transitory provision) for the registration of foreign degrees in medicine possessed by practitioners registered on British or Irish qualifications which have been obtained after proper examination, and prior to the passing of the Act.

As to previous proposals or suggestions on the subject of the Act, the clause relating to foreign and colonial practitioners contained in Lord Ripon's Bill of 1870 differed widely from the provisions now enacted, since it would have confined registration to persons over forty years of age, and who had been not less than ten years in practice. The General Council had previously (July, 1869) expressed itself in favour of provision being made to enable it, by special orders, to dispense with such conditions of the Medical Acts and such of the regulations made under them as it should think fit, where foreign or colonial practitioners applied for registration. A resolution altogether unfavourable to the registration of foreign degrees proceeding upon a communication from graduates holding such degrees, themselves apparently already upon the Register—was subsequently, in 1876, arrived at by the General Council. A close approach, however, to what has now been enacted was made by the President of the General Council in 1879 in a communication written for the Select Committee of that year. There was at that time in France an agitation for the exclusion of foreign practitioners from the privilege of practising in France. The President thought that, if a joint committee of foreign and English representatives could be got to consider the matter, "it might be possible to bring about reciprocal action which would be just and beneficial to all parties"; and which "would tend to secure a wise and uniform standard of medical education, whether practical or scientific, in all civilised communities."

*** The above article was unavoidably omitted from our last issue.

OUTBREAK OF ANTHRAX IN CATTLE, AND FIVE MEN INFECTED.

By JAMES A. FRASER, L.R.C.P. Lond., M.R.C.S.

THINKING that a history of the following outbreak of anthrax might prove of interest to many readers of THE LANCET, I send a short sketch of it.

On June 6th a cow was taken suddenly ill, the cause of the illness being attributed to the excessive heat; it was slaughtered, and the meat, not being condemned, was disposed of. No further case occurred until July 1st, when a second cow was taken ill, [illegible] died. Splenic fever was diagnosed, and found correct on post-mortem examination. On the 6th two beasts, a cow and pony, were affected and died, splenic fever in both being found to be the cause of death. On the 11th a sow was taken ill, and on inspection was found to be enormously swollen. This sow was fed on the offal of the cow that died on July 6th. On the 12th a fourth cow died of splenic fever. The entrails of this last cow were buried in a dung-heap situated at the top of an incline in the pasture. All the above beasts were pastured in the one field, which had never had a case of splenic fever in it before June 6th, a stagnant pond being supposed to be the source of infection.

On July 24th I was informed that Henry P——, by occupation an odd job man about the market, and who was in the habit of wheeling offal from the slaughterers, had been admitted into the union infirmary, the time of admission being 4.30 P.M. He was seen by my assistant, Dr. James Lawson, the note on his admission card being "mitral disease and pneumonia." His condition was as follows:—Cyanosis of face, ears, hands, and arms up to elbows, and of feet and legs up to knees; breathing very laboured, 40 per minute; dulness over base of left chest at back, and slightly over base of right lung; loud râles, especially in left chest; heart sounds rapid and faint, and covered by the chest râles; radial pulse not to be felt; perspiration standing in beads on the face. The patient spoke once, and said that he was infected while helping to dress a cow. The date of such dressing could not be ascertained, as he became comatose, and died at 8.30 P.M.

A post-mortem examination was made forty hours after death, the following being a copy of the report: Skin of face jaundiced; lips livid; cyanosis marked; hypostatic congestion of skin of body; an ulcer at junction of upper and middle thirds of right tibia; no other skin lesion found. The pericardium contained an ounce and a half of blood-stained serum. Pleura on right side non-adherent; on left side, new and old adhesions present, very firmly bound down at the base, the lung tearing on attempting to remove it. Right lung congested; left lung congested and rotten at the base; no sign of abscess anywhere; lung floating. Heart: Right side contained clot; both valves normal. Left side, wall hypertrophied; full of coagulated blood, which was soft, not firm; the lining membrane much stained. Aortic valves would not admit the finger; patches of atheroma were present on the aorta; patches of granulation on ventricular surface of the valves. Mitral valve puckered and incompetent, and granulations on the ventricular surface; admitted two fingers. The liver weighed 3 lb. 5 oz.; it was healthy, but congested. The spleen was not enlarged, but was congested and broke down easily. Kidneys: Weight, 11¾ oz.; congested and tough. Intestines very congested in patches, corresponding to the long axis of intestine; congestion of the intestines was most marked toward the ileo-cæcal valve; the glands of Peyer showed not abnormal; solitary glands enlarged; mesentery much congested. Brain: Vessels full; on section the vessels stood out full of clot; ventricles empty. The pleural, pericardial, peritoneal, and meningeal spaces contained blood-stained serum. On examining the blood, dried on cover glasses, stained with gentian violet, and mounted in balsam, great numbers of anthrax bacilli, some very long, were found in every field. On examining scrapings of the spleen prepared in the same way, more numerous but shorter anthrax bacilli were present.

On making inquiry, Mr. Mackenzie, under whose care the above patient was before admission into the union, has furnished me with the following list of cases which have been under his care:—

1. G——. Summoned to attend fifteen hours after infection; found patient with pneumonia and hæmoptysis; two malignant pustules on right forearm. Died four hours after seeing him.

2. S——. Large malignant pustule on right cheek; great swelling; free application of absolute phenol; large slough; no secondary mischief. Recovery in three weeks and a few days.

3. K——. Malignant pustule on left brow, treated with absolute phenol. Recovery in a fortnight.

4. M——. Questionable pustule on hand; seen early; arm œdematous and inflamed. Used absolute phenol. Recovery in ten days.

It will thus be seen that Mr. Mackenzie had five cases under his care, three of which were recovering.

The fact of anthrax not coming under the Contagious

Diseases of Cattle Act prevents the local inspector from proclaiming the pasture on which the outbreak occurred as an infected area, so that other beasts may be turned down on it and so become infected. If the meat is not condemned it may become a source of infection to human beings. The slaughterers, not being aware of the danger attending the skinning and cleaning of such infected cattle, are very careless, and run great risks—e.g., eating pieces of the suet, holding the skinning knives in their teeth, &c.; and, last but not least, the offal not being burned, but buried, proved to be a fresh source of infection, as may be seen by what follows.

On July 26th, the veterinary surgeon (Mr. Gray) was called up early in the morning to see a horse which had been taken ill and died, the symptoms being great thirst, purging, and staggering. On post-mortem examination splenic fever was found to have been the cause of death. Four hours afterwards he was called to the same field to a pony with the same symptoms; this also died; cause of death splenic fever. These two beasts had been feeding round the manure heap, in which the offal from the cow which died on July 12th had been buried. I was given specimens of the blood of the horse and pony, the buffy coat having already formed. On drying on covered glasses, staining with methylene blue, and mounting in balsam, very numerous and well-marked anthrax bacilli were found. I have shown the above specimens of human blood and spleen scrapings, and of the blood of the horse and pony, to Mr. Davies-Colley and Mr. Jacobson of Guy's Hospital, and both declare them to be doubtless specimens of anthrax bacilli.

THE AFGHAN BOUNDARY COMMISSION.

THE Medical Report of the hospital service connected with the escort which accompanied the Afghan Boundary Commission in 1884–85, by Surgeon-Major Charles, of the Indian Medical Service, contains some very interesting information regarding the countries through which it marched, and the health of the men under the arduous work they had to perform. The escort, consisting of 7 officers, 455 fighting men and 286 followers, a half field hospital with 1 medical officer, 3 subordinates, 10 medical establishments, and 56 followers, left Sirimungli, near Quetta, on Sept. 22nd, 1884, and reached their winter quarters at Bala Murghab on Dec. 13th. Here they remained in a standing camp till Feb. 15th, when they marched to Gulran in very severe weather, arriving at their destination on Feb. 23rd. On the 3rd and 4th they moved in two parties across the [illegible]ed Pass to Tirpul, near Khusan. The second party encountered a sudden storm of great violence in the Pass, and lost by it twenty-four men, with many mules, camels, and some horses. "The men of this division continued to arrive at Tirpul in driblets for some days. During this time and for long after, the half field hospital had a sufficiency of work, and with most excellent results to the storm-tossed sick." After the recall of Sir P. Lumsden in May, the escort, divided into two parties, was stationed in or near the Herat Valley, occupying various camps till the end of September, when the strength was reduced, and a return party formed of 254 fighting men and about 220 followers. These started from Mamisak on Dec. 1st, and reached Sirimungli on Jan. 22nd, 1886, having been one year and four months employed on this service. The total distance marched during the expedition was 2316 miles. The rate of marching on the upward journey to Bala Murghab averaged, exclusive of halts, eighteen miles a day, and on the return from Mamisak, fifteen and a half miles. On the way up, the marching was done at night; on the way down, by day; and the health of the men was decidedly better during the latter, but this may have been due, in a considerable degree, to better arrangements, better water, and the men being more inured to marching. On this service the men were exposed to great vicissitudes of temperature, the thermometer in 1885 having ranged between zero in January and 104° in July. "The extremes of temperature are at times very great, as many as 70° or 80° F. between day and night temperatures." During the winter at Bala Murghab the men were lodged in Kibitkas, and every care was taken to protect them from the damp. Dr. Charles says that "in the [illegible] weather an equable temperature can be maintained [illegible] them. ..... Looking back at the time spent in Kibitkas, properly prepared as I have noted, I have no hesitation in saying that they served their ends in a way that could not be surpassed, and I attribute to them, in a measure, the small mortality among the sick treated in hospital. Kibitkas can be made cool in hot weather, and warm in cold weather; and the ventilation at all times, with care, can be rendered excellent." The information given respecting the health of the men is unsatisfactory—probably unavoidably so, owing to the frequent moves and to the party being so often broken up; but there is no statement of the mortality except that already noted as arising from the storm in the Ao Safed Pass, and the admissions into hospital are only recorded for broken periods, while the principle on which the return of out-patients has been made up is not stated. We can, therefore, only draw some general conclusions as to the diseases from which the troops suffered. On the march up there seems to have been a considerable prevalence of dysentery among both the fighting men and the followers, but this apparently ceased after reaching Bala Murghab. Surgical injuries and diseases, and fevers, were the chief causes of admission into hospital after that date. In the first two months of 1885 cases of bronchial catarrh were very frequent among the out-patients of both classes, and next to these boils and ulcers, and dyspepsia. In June, July, and August a considerable number of cases of conjunctivitis occurred, attributed chiefly to the dust and sand. It is worthy of remark that, notwithstanding the very low temperature of the winter, there were scarcely any cases of frost-bite till after the march across the Ao Safed Pass. This immunity was probably due to the housing of the men in the kibitkas and to providing them with a liberal supply of warm clothing.

Among the diseases most prevalent in the civil population of the country, Dr. Charles specially notes paroxysmal and typhoid fevers, rheumatism, dyspepsia, bronchial catarrh, syphilis, scurvy, and worms. Cholera is said to have been very rife in the Herat Valley in the past, but it did not appear among the men of the escort or the followers. No cases of sunstroke occurred among the men, and although many of them were bitten by camp and pariah dogs, none of them suffered from rabies. Some interesting notes are given of cases, and of the remedies found most efficient in their treatment. We would merely notice the internal use of hot water in ague and remittent fever, instead of the usual diaphoretics. Dr. Charles says that he never found it fail to give relief. "Pain would vanish, giving place to a feeling of ease; thirst would be no longer felt; the burning skin would be suffused in a gentle sweat; the aching head, with heavy eyelids, would sink to rest in a calm and placid slumber." The water must be hot, not tepid—"so hot that it can just be swallowed without scalding, and no more,"—and is to be followed by quinine.

There are, we think, some valuable practical lessons to be derived from the experience gained on this expedition. We would note the importance, from a health point of view, of marching the troops by day instead of night, but this, of course, would not be applicable to the hot summer months; the advantage of housing the men in winter in a manner adequate to protect them from the excessive cold, and of providing them with sufficient warm clothing; the propriety of avoiding the occupation of old buildings, such as the robats and forts, as quarters for the men, which at one time it was proposed to do, but which was abandoned on the recommendation of the medical officer. Dr. Charles, in some notes on the transport of the sick, has pointed out the disadvantages of the Moseley Khajawa, as supplied to the expedition, and recommends the Herat Khajawa, as being much better suited, especially for winter use, in such a climate. He has also called attention to the necessity of an inspection, by a medical officer, of the followers who are to accompany the troops on service, as men unfit for field service or the inclemency of a severe climate are often taken, and prove a serious encumbrance to the force. He also strongly advises the erection of urinals for standing camps. "No urinals were used in the standing camps (in spite of remonstrances), so that in a short time the top soil became saturated with urine and a breeding-place for flies and noxious effluvia, &c."

AT the Newcastle-under-Lyme Police-court on the [illegible] inst., a Macclesfield [illegible] fined £10 for exposing [illegible] for sale a quanti[illegible] for human food.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Annual Calendar has just been published by the Council of the College. From it we ascertain the following facts:—

It appears that there are 1124 Fellows on the roll of the College, of whom 639 obtained the Fellowship by examination, 7 were elected as Members of twenty years' standing under Section 5 of Charter 15 Vict., and 2 are *ad eundem* Fellows. There are 17,040 Members, and 957 Licentiates in Midwifery (the examination for this licence having been suspended for the last eleven years). The Licentiates in Dental Surgery number 590.

The examiners in Elementary Anatomy and Physiology, appointed in conjunction with the Royal College of Physicians, under the scheme for an Examining Board in England, are elected annually. There have been four examinations during the past year, 716 candidates presenting themselves, of whom 474 passed in both subjects, 77 in Elementary Anatomy, and 96 in Elementary Physiology; 55 candidates were referred in both subjects; 63 were referred in Elementary Anatomy, and 63 in Elementary Physiology. The fees received from candidates for this examination amount to £3581 16*s.* 3*d.*, the Examiners receiving in fees £506 15*s.*

The examiners in Anatomy and Physiology appointed in conjunction with the Royal College of Physicians, under the scheme for an Examining Board in England are elected annually. They have conducted the Primary Examinations for the diploma of Member under the old regulations, as well as the Second Examination of the Examining Board, and have held during the year four examinations, at which 1079 candidates presented themselves, of whom 262 passed in both subjects, 173 in Anatomy, and 246 in Physiology; 97 were referred in both subjects, 240 in Anatomy, and 214 in Physiology. The fees received from the candidates for this examination amount to £4363 16*s.*; the examiners receiving £2259.

The Board of Examiners in Anatomy and Physiology for the diploma of Fellow consists of nine members annually elected by the Council from the Fellows of the College, and has held during the past collegiate year two examinations, 117 candidates presenting themselves, of whom 62 passed and 55 were referred. The fees received from this examination amount to £829 10*s.*; the Board receiving in fees £526 10*s.*

The Court of Examiners consists of ten members, elected by the Council from the Fellows of the College, all of whom, however, are members of the Council, except Dr. Humphry, Mr. John Langton, and Mr. T. Pickering Pick. During the year the Court has held two examinations for the Fellowship and four for the Membership. At the former there were 51 candidates, 28 of whom passed, 19 being referred for one year and 4 for six months. For the Membership there were 1048 candidates, 319 of whom obtained their diplomas, and 270 passed in Surgery only; 103 were referred for three months, 320 for six months, 14 for nine months, and 22 for one year. The fees paid by candidates amounted to £12,737 16*s.*; the fees paid to the Court of Examiners amounting to £6027 7*s.*

The Board of Examiners in Dental Surgery has held two meetings for the examination of twenty-eight candidates, twenty-one of whom obtained their diplomas. The fees paid by them amounted to £220 10*s.*, of which the Board received £88 4*s.*

The income of the College from all sources during the past year amounted to £40,712 11*s.* 5*d.*, derived principally, as already shown, from fees paid by candidates for the diplomas of the College—viz., £21,753 8*s.* 3*d.* Rents from chambers adjoining the College produce £1520 0*s.* 6*d.*; dividends on stock, £1154 19*s.* 2*d.*; from members of the Council and Court of Examiners on their election, £76 6*s.*; from sale of stock, £12,500 7*s.* 1*d.*; from trust funds and sale of Calendar and Synopsis, £275 6*s.* The expenditure for the year amounted to £40,137 5*s.* 7*d.*, the largest item being £12,816 7*s.* 7*d.* for purchase of house, No. 44, Lincoln's-inn-fields. The next largest amount appears in fees paid to examiners—viz., £9446 6*s.* Salaries, wages, and pensions for officers and servants of the College in the three departments—library, museum, and office—amount to £4645 14*s.* 6*d.* Taxes, rates, diploma stamps, and insurance absorbed the sum of £1670 1*s.* 9*d.* Half expenses for new Examination Hall, £5978 5*s.* 5*d.* Under miscellaneous items, extraordinary expenses, alterations and repairs, the sum of about £4000 appears to have been expended.

THE PHARMACEUTICAL SOCIETY.

THE introductory address at the commencement of the forty-fifth session of the School of Pharmacy was delivered on the 6th inst., by Sir Henry W. Acland, Regius Professor of Medicine in the University of Oxford, and President of the General Medical Council. After alluding briefly to the future of Science, he spoke of some of the medical agents contained in the Pharmacopœia of 1651—silkworms, toads, swallows, ants, &c.; and remarked that it was surprising how so monstrous a list could have been authoritatively issued after Linacre had lived and taught in that great college which he founded, and which was destined to shed lustre on the history and character of medicine. Sir Henry next spoke of the step about to be taken by the Pharmaceutical Society—viz, the establishment of a laboratory for special research into the exact chemical constitution of drugs and alleged remedies, with a view to the precise fixing of the constitution of alkaloids of acknowledged or hypothetical value, and to the discovering, and generally the guaranteeing to the experimental therapeutist and the physiological inquirer, absolutely pure bodies of known chemical constitution, whether existing in commerce or not. Sir Henry then reviewed the progress of the Pharmacopœia, and advocated the publication of a small volume which would lay down, by international consent, the mode of obtaining with certainty the best remedies made in the best manner, with rules of how to preserve them in all climates, and how readily to distinguish them. He regretted that no steps had been taken to obtain representatives from India, from the Dominion of Canada, and from Australasia to co-operate with England in researches connected with the Pharmacopœia, this being especially desirable owing to the admission after the present year of colonial and foreign practitioners to the Medical Register. The conclusion of the address was devoted to an exhortation to diligence, cleanliness, order, and exactitude on the part of the students in their studies, and in their future career as dispensers.

HOSPITAL REUNIONS.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.

AT the distribution of prizes to the successful students of the Middlesex Hospital, which took place on Monday last, after Dr. Biss's introductory lecture the chair was taken by Dr. Headlam Greenhow, F.R.S., who was formerly so long attached to the hospital. The Dean, Mr. Pearce Gould, in his report, stated that plans for an extension of the school buildings had been prepared, and that the erection of these buildings and those of the proposed residential college would shortly commence. Dr. Greenhow addressed a few words to the students, and a cordial vote of thanks to him was passed with acclamation. The customary annual dinner took place at the Holborn Restaurant in the evening. The chair was taken by Mr. Andrew Clark, F.R.C.S, who has held the office of Dean for ten years. The gathering was an unusually large one, and the post-prandial speaking was lightened by most excellent singing and music by Mr. Ganz, Dr. Pringle, Mr. Critchett, Mr. Hepburn, and Mr. Fulkerson, the proceedings terminating at a late hour with the whole company joining in "Auld Lang Syne." The toasts included "The Middlesex Hospital Medical School," given by the chairman and responded to by Mr. Hulke, F.R.S.; "The Middlesex Hospital," proposed by Dr. C. West and acknowledged by Major Ross, M.P., chairman of the Weekly Board; "The Past and Present Students," given by Mr. T. W. Nunn, and replied to by Sir Oscar Clayton on behalf of the past students, and Mr. W. G. Nash on behalf of the present students; the health of the "Orator of the Day" was proposed by Dr. Edis and acknowledged by Dr. Biss; that of "The Chairman" was given by Mr. Morris; and the toast of "The Visitors," which was

Boliv. Lending Library

given from the chair, was responded to by Mr. Burdett, who, in concluding, proposed the health of the new Dean, Mr. Pearce Gould. The gathering was acknowledged by all to have been a great success, and it was marked by much cordiality and heartiness.

UNIVERSITY COLLEGE.

THE annual dinner of the old and present students of the Faculty of Medicine took place at the Freemasons' Tavern on Oct. 4th, under the presidency of Sir William Roberts, Professor of Medicine in the Victoria University, Fellow of University College. The chairman was supported on his right by Dr. George Buchanan, and on his left by Professor Michael Foster. Among those present were Professor Russell Reynolds, Professor Burdon Sanderson, Dr. Henry Maudsley, Dr. William Wood, Dr. Morris (Spalding), Mr. Waggett, Mr. Bluett (Chesterfield), Mr. Humphreys (Shrewsbury), Mr. Kiallmark, Dr. Allen (Hastings), Dr. Snow (Bournemouth), Dr. Price (Cardiff), Mr. William Gill, Mr. Bernard Roth, Mr. Embleton (Bournemouth), Dr. C. Beevor, Mr. Hodson (Brighton), Mr. Peter Cooper (Blackheath), Mr. Buckston Browne, Dr. Percy Gabb (Guildford), Dr. Amand Routh, Mr. W. Rigden, Mr. J. Prince Bartlett, Dr. Magrath (East Grinstead), Mr. Foster Macgeah, Mr. Harvey (Bromley), Mr. Twynam (Sydney, N.S.W.), Dr. Easmon (Gold Coast), Dr. Pasteur, Mr. Campbell Williams, Mr. Drew (Oxford), Dr. Lewers (London Hospital), Mr. Williams-Freeman (Portsmouth), Mr. Stewart Norman (Havant), Mr. Swift, Mr. Peter Giles (Hereford), Mr. W. A. Meredith, Dr. Cock, Mr. Bowreman Jessett, Mr. H. A. Powell (Beckenham), Mr. Copley (Wisbech), Mr. Fraser Stokes, Mr. Frankish, Dr. Penrose, and others. The present members of the hospital staff and the professors of the Medical Faculty of the College were all present, with very few exceptions; and these, with a large contingent of students, made up a company of about 100. There was some excellent speaking from the chair, and from Dr. Buchanan, Dr. Michael Foster, Dr. Burdon Sanderson, Dr. Wilson Fox, and Dr. Grailly Hewitt; and the proceedings were enlivened by some first-rate singing by Dr. F. T. Roberts, Dr. Beevor, Mr. Campbell Williams, and Mr. Copley. This very pleasant reunion of old friends was brought to a close at about 11 o'clock.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

After the delivery of the introductory address on the 4th inst., the Dean read his annual report for the year, and drew attention to the fact that all the first-year's students who came under the new regulations had passed the examination recently instituted by the conjoint Board of the Royal Colleges of Physicians and Surgeons in Anatomy and Physiology at the end of the first winter session. The prizes gained during the past year were given away by the Venerable Archdeacon Farrar, who afterwards addressed some eloquent remarks to the students on the connexion between the medical profession and the clerical profession and literature, giving numerous illustrative examples, and he concluded by exhorting his hearers to respect humanity and to respect themselves. The annual dinner of the staff and past and present students was held in the evening at the Holborn Restaurant. The Hon. Mr. Justice Wills was in the chair, and among the guests were Col. Duncan, R.A., M.P., Col. Sparkes, Major Davis, the Rev. T. S. Echalaz, &c.

ST. THOMAS'S HOSPITAL.

A CROWDED audience of students and their friends assembled in the operating theatre to listen to the introductory address of Dr. Bristowe, on Friday last. Nearly all the members of the hospital staff and lecturers were present, and several students from other hospitals. The address, which we publish this week, was listened to with great attention, abounding, as it did, in sketches of bygone members of the staff who helped to make it famous, and on its completion the lecturer was greeted with loud applause. In the evening the annual dinner took place in the Governor's Hall, at which there was a good attendance. Mr. C. W. Chaldecott, of Dorking, occupied the chair, a most pleasant evening being spent. The chairman proposed the usual toasts; Dr. Stone, in a witty speech, "The Health of the Visitors," which was replied to by Professor Wm. Thomson and Dr. Savage. Alderman Stone (treasurer) replied for the hospital. Dr. Bristowe, F.R.S., proposed "The Chairman," and Mr. J. R. Lunn, in the absence of Mr. John Simon, C.B., F.R.S., "The Medical School," to which Dr. Ord replied, referring to its increased prosperity, and the additional accommodation recently provided in the anatomical and other departments, and to changes in the teaching. Mr. Le Gros Clark, Mr. John Croft, Dr. Alfred Carpenter, and Dr. H. W. G. Mackenzie also spoke.

GUY'S HOSPITAL.

PUPILS' PHYSICAL SOCIETY.

IN order to mark the beginning of the session, the Pupils' Physical Society held their first meeting on the evening of October 4th, in the anatomical theatre, which was completely filled, there being only standing room for several members both past and present. The treasurer and many members of the staff attended. Dr. Wilks, LL.D., F.R.S., was in the chair, and in a short opening address he first referred to the great loss the hospital had sustained in the death of Dr. Moxon, alluding especially to the manner in which he had by his untiring industry, energy, and skill enriched the pathological department by the addition to it of the well-known and beautiful series of water-colour drawings of pathological specimens which now hang on the walls of the post-mortem theatre. Dr. Wilks pointed out that, although the profession sustained from time to time great individual losses, yet the profession itself went on, and we must by hard work keep ourselves ever ready to fill up the gaps in the ranks. After congratulating the new students upon having entered a school which he so loved, of which he thought so highly, and at which the opportunities for work in all the departments were so numerous, the speaker went on to tell the students of the antiquity of the Physical Society of Guy's, which is the oldest medical society in London. He then mentioned the distinguished men, such as Dr. Jenner, who had spoken from the same theatre as that in which the Society now holds its meetings, and read extracts from the address delivered on similar occasions to the present, many years ago, by such men as Dr. Babington and Mr. Allen. Finally, after telling the new students that by joining Guy's they had taken upon themselves an obligation to work for the credit and fair name of the school to which they were attached, he called upon the reader of the paper of the evening to begin. Dr. Ryle, whose paper was entitled "The Rise and Progress of Medicine," gave a most interesting and full account of our advance from the time of Hippocrates downwards, showing that that father of medical art and science had a most wonderful insight into many of the problems of his craft, and that often there was an exactitude in his observations which it would be well if we nowadays were sometimes to imitate. Dr. Ryle proceeded to read several very instructive reports of Hippocrates' cases, making comments upon them in passing. He then touched upon all the epoch-marking periods of medicine, alluding especially, first of all, to Galen, who had done as much to retard medicine as to advance it by promulgating with his great authority many ill-founded theories. After alluding to Harvey and some of the later masters in medicine, Dr. Ryle concluded his paper. A brisk debate, carried on by the past and present members of the society, followed, and the reader of the paper replied. A vote of thanks to the treasurer was proposed by Mr. Lund, the senior house-surgeon, and seconded by Mr. Beard, the junior house-surgeon. The Treasurer, in replying, alluded to the great loss which the governors felt in the death of Dr. Moxon. He said it was a great pleasure to come to these meetings, and that he never failed to hear something which gave him material for deep thought for some time to come. Mr. E. W. Goodall, M.B, the senior house-physician, proposed, and Mr. Beard seconded, a vote of thanks to Dr. Wilks for presiding. In the course of his remarks Mr. Goodall said what a pleasure it was to the students that Dr. Wilks, although consulting physician to the hospital, still came down often in the afternoon and gave them the benefit of his great knowledge. After a brief reply from Dr. Wilks the meeting broke up. During the evening the museums were lit up, so that the past students had an opportunity of refreshing their memories by again looking at the famous specimens and wax models for which the Guy's museum is so well known. Many microscope specimens were exhibited, and all who attended appeared to have had a very pleasant evening.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Islington.—The population of St. Mary, Islington, may be taken at about 318,633, and in this the death-rate was 16·7 for 1885; this being the smallest death-rate on record. The birth-rate was 30·3 per 1000. Amongst the zymotic diseases small-pox was severely epidemic during the first six months of the year, measles was fatally epidemic, and the deaths from diphtheria, which had been rapidly increasing for some years past, amounted to 138. A large number of the sick were removed to the Metropolitan Asylums Board hospitals and to the Highgate Small-pox Hospital. Of the small-pox cases 42·9 per cent. died amongst the unvaccinated, whereas the rate was only 13·7 per cent. amongst the vaccinated. During the year the Vestry destroyed 421 articles which were infected, including 125 beds, and all these were replaced at the cost of the public, the amount thus spent reaching close upon £300. Dr. Meymott Tidy includes in his report tables as to the analysis of the New River Company's water, and as to the amount used per house; details are also given as to the licensing of slaughter-houses and cow-houses, as to summonses taken out under the Sanitary Acts, the renovation of certain of the dwellings of the poor, and action under the Sale of Food and Drugs Act. Having regard to the exigencies of public opinion and to the freer exercise of the right of complaint by the inhabitants, a large extension in the way of sanitary inspection became necessary in the parish, and besides other modifications four additional inspectors have been appointed, and regulations have been made defining more clearly the several duties of the inspectorial staff.

Surbiton Urban District.—During 1885 the death-rate for Surbiton was only 9·7 per 1000, and two deaths each from whooping-cough and diphtheria were the only ones due to zymotic diseases. The diphtheria cases are referred to as sporadic only. There is no description of the sanitary circumstances existing in the district, and apart from a list of nuisances dealt with, which is supplied by the inspector of nuisances, and a statement that the town is still without any hospital for infectious diseases, the wants of the district are not referred to. Perhaps, with a repeated low death-rate, the sanitary wants of the district are but few.

Huddersfield Urban District.—The general death-rate from all causes in 1885 was 20·1 per 1000 in Huddersfield, and that from the seven principal zymotic diseases 1·4, this latter being one of the lowest rates on record. In his report, Dr. Cameron draws attention to an excessive amount of death from "consumption" in the borough, and in this connexion he refers to density of population as facilitating the spread of a disease now admitted to be communicable. Thus, overcrowding becomes, from the point of view of this mortality, a vital one in the matter of public health, and anything tending to the undue aggregation of people, especially as regards their sleeping accommodation, needs to be specially dealt with where any tendency to excessive phthisis mortality is met with. During the year the authority's hospital has been in general use, and at one time the amount of accommodation was found to be insufficient. The site is, unfortunately, a restricted one for such a borough, although some of the accommodation it provides is very good. Scarlet fever was prevalent, and its spread is stated to have been in part due to unnotified cases. No such thing as intentional withholding of certificates on the part of medical men is suggested, but cases in which there was doubt as to diagnosis led to some difficulty in this respect. Where the notification was from the householder alone, there was tardiness, and Dr. Cameron thinks that some parents preferred wilfully to remain ignorant of the fact that their children had scarlet fever, so as to avoid the notification. But there has been no increasing antipathy to compulsory notification, and on the whole the Act is said to work well.

Wallasey Urban District.—As in so many other districts, the death-rate for Wallasey during 1885 was exceptionally low, the rate being 14·9 per 1000; the infantile death-rate and that from zymotic diseases were also low. In connexion with the general sanitary administration of the district, eighty soil-pipes were ventilated, several hundre drain-pipes were disconnected, houses were supplied witl proper water-supply, and a large number of other improve ments were effected. In 1884 a thorough systemati inspection of the district was made, and, as is usually th case, this was the forerunner of a large amount of detaile sanitary work, which must necessarily go to improve th healthiness of the town. Full details of this excellent worl are given by Dr. Craigmile in the report under consideration

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5539 birth and 3592 deaths were registered during the week ending Oct. 2nd. The annual death-rate in these towns, whicl had been equal to 22·6 and 21·0 per 1000 in the preceding tw weeks, further declined last week to 20·0. During the thirteer weeks ending last Saturday the death-rate in these town averaged 20·4 per 1000, and was 0·8 below the mean rate ir the corresponding periods of the ten years 1876-85. Th lowest rates in these towns last week were 15·2 in Brighton 16·9 in Bradford, 17·0 in London, and 18·2 in Derby. Th rates in the other towns ranged upwards to 27·7 in Leeds 27·7 in Bolton, 29·2 in Manchester, and 29·4 in Preston The deaths referred to the principal zymotic diseases in th twenty-eight towns, which had been 1202, 1133, and 93 in the preceding three weeks, further declined last week to 746; they included 532 from diarrhœa, 61 from scarlet fever, 59 from "fever" (principally enteric), 33 from diphtheria, 32 from measles, 29 from whooping-cough, and no one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in London Huddersfield, and Plymouth; and the highest in Norwich, Hull, Wolverhampton, and Preston. Diarrhœa caused the highest death-rates in Wolverhampton, Hull, and Preston the mean rate in the twenty-eight towns being considerably above the average for the last week in September. The mortality from "fever" was greatest in Portsmouth, Bolton, Norwich, and Plymouth; from scarlet fever in Liverpool, Bristol, and Salford; from whooping-cough in Norwich and Wolverhampton; and from measles in Halifax. The 33 deaths from diphtheria included 20 in London, 4 in Liverpool, 2 in Leeds, and 2 in Cardiff. Small-pox caused no death in London and its outer ring, or in the twenty-seven large provincial towns; and only one small-pox case was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 110, 168, and 154 in the preceding three weeks, further rose last week to 187, but were 35 below the corrected average. The causes of 87, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Blackburn, Wolverhampton, and Halifax. The largest proportions of uncertified deaths were registered in Huddersfield, Manchester, Oldham, and Nottingham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·6, 18·8, and 16·8 per 1000 in the preceding three weeks rose again to 18·3 in the week ending Oct. 2nd; this rate was 2·3 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 9·8 and 13·0 in Perth and Paisley, to 19·9 in Aberdeen and 21·7 in Glasgow. The 452 deaths in the eight towns last week showed an increase of 37 upon the number in the previous week, and included 34 which were referred to diarrhœa, 14 to whooping-cough, 8 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 2 to diphtheria, 1 to measles, and not one to small-pox; in all, 63 deaths resulted from these principal zymotic diseases, against 93, 73, and 78 in the previous three weeks. These 63 deaths were equal to an annual rate of 2·6 per 1000, which was 1·7 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had been 57, 45, and 43 in the preceding three weeks, further declined last week to 34, of which 15 occurred in Glasgow, 6 in Dundee, 4 in Edinburgh, 4 in Aberdeen, and

3 in Leith. The mean annual death-rate from diarrhœa in the Scotch towns last week was again considerably below that which prevailed in the large English towns. The fatal cases of whooping-cough, which had been 20, 11, and 18 in the previous three weeks, declined again to 14 last week, and included 10 in Glasgow and 3 in Edinburgh. The 8 deaths from scarlet fever, of which 7 occurred in Glasgow, were within one of the number in the preceding week. The 4 deaths referred to "fever" were below the average for the season, and corresponded with the number in the previous week. The fatal cases of diphtheria and measles were also below the average. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 65 in each of the preceding two weeks, were 67 last week, and exceeded the number in the corresponding week of last year by 9. The causes of 66, or nearly 15 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 27·5 and 24·7 per 1000 in the preceding two weeks, further declined to 22·8 in the week ending Oct. 2nd. During the thirteen weeks of the quarter ending last Saturday the death-rate in the city averaged 22·1; the mean rate during the same period was 18·7 in London and 17·5 in Edinburgh. The 154 deaths in Dublin last week showed a decline of 13 from the number in the previous week, and included 23 which were referred to diarrhœa, 8 to scarlet fever, 2 to "fever," and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus 33 deaths resulted from the principal zymotic diseases, against 39 and 30 in the preceding two weeks; they were equal to an annual rate of 4·9 per 1000, the rates from the same diseases last week being 2·4 in London and 1·6 in Edinburgh. The fatal cases of diarrhœa, which had been 29 and 25 in the previous two weeks, further declined last week to 23. The deaths referred to scarlet fever, which in the preceding two weeks had been 2 and 3, rose last week to 8, a higher number than in any week since the middle of last year. Five inquest cases and 4 deaths from violence were registered; and 38, or nearly one-fourth of the deaths, were recorded in public institutions. The deaths of infants showed a further decline from those returned in recent weeks, while those of elderly persons showed a slight excess. The causes of 23, or nearly 15 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

DR. GLOVER'S CANDIDATURE AND THE BIRMINGHAM COMMITTEE.

To the Editor of THE LANCET.

SIR,—The letter of Dr. Strange, the chairman of the Birmingham Committee, which you published on Oct. 2nd, and your own leader of that date, informed the profession that from regard to my place in the test-ballot by that committee they have now invited me to be their third candidate. The profession will naturally expect to hear the decision of my committee and my own opinion in regard to that invitation. I will ask you, with this view, kindly to publish my letter to Dr. Strange (which contains the resolution of my committee) in reply to his overtures, acting as chairman. In announcing this resolution, I wish to acknowledge with gratitude the courtesy of Dr. Strange and his colleagues. I am well aware of the value of organisation, but, at all hazards, we must preserve freedom.

Believe me, Sir, your obedient servant,

Highbury-place, N., Oct. 5th, 1886. JAMES GREY GLOVER.

"25, Highbury-place, Oct. 2nd, 1886.

"DEAR DR. STRANGE,—I lose no time in informing you of the result of the consideration by my committee of the proposal that I should stand as the third candidate of your nomination for the office of direct representative of the profession in the General Medical Council. The resolution of my committee is as follows:—

"'That this committee, having considered the letters written by Dr. Strange and Mr. Ker on behalf of the Birmingham Committee, in which Dr. Glover is informed that he has been adopted as the third candidate on their list, and in which, further, they express the desire that this committee, formed (two months since) to promote Dr. Glover's candidature, should amalgamate with the Birmingham Committee to promote the election of Messrs. Wheelhouse, Foster, and Glover—the three candidates now selected by the Birmingham committee as the most suitable to represent the profession in the General Medical Council,—do hereby resolve that the best thanks of the committee be given to the members of the Birmingham Committee for their proffered aid in advancing the election of Dr. Glover, and for the way in which they have mentioned his suitability for the post, as well as his claims on the profession; but, as many members of his committee have already promised their support to other candidates, and many other members decline to have their freedom of selection curtailed, it is impossible for the two committees to amalgamate to fulfil the objects of the Birmingham Committee.'

"I need not say how gratifying it is to me to stand well in the estimation of so many members of your committee; nor what a pleasure it would have been to me to co-operate with you, and to be associated in a joint candidature with Mr. Wheelhouse and Sir Walter Foster. But I am bound to say that I heartily concur with my committee. What we want above everything is to aid the free and spontaneous expression of the views and preferences of the medical profession, and to avoid mechanical ways of tying candidates and voters together. I shall still prize the support of the individual members of your committee, and trust to your kindness and courtesy, of which I have had not a little proof, to believe that, in electing to stand as an independent candidate, I am only doing what I feel to be right in the interest of the profession, which we all have at heart.

"Believe me, dear Dr. Strange, yours very truly,

——— "JAMES GREY GLOVER."

To the Editor of THE LANCET.

SIR, I must say I am somewhat surprised to see how few of the candidates are what may be called typical general practitioners—i.e., men who hold union and club appointments, and have to face practice of all kinds and amongst all classes. I do not think the fact of a man's having once seen that kind of practice is sufficient proof of his sympathy with general practitioners. I should like to ask candidates

1. Are you now in *bonâ fide* general practice, with union and club appointments, and *do you intend to remain in your present position?* 2. Will you aim at raising the standard of general education to the level of that required in most foreign countries say that of a B.A. degree at Oxford or Cambridge? I am, Sir, yours truly,

Woolwich, Oct. 4th, 1886. THEODORE MAXWELL, M.D.

To the Editor of THE LANCET.

SIR,—The circumstances that led to the formation of a committee whose object should be to endeavour, firstly, to find who would be likely to be the best representatives of the profession on the General Medical Council, and, secondly, to induce these to become candidates, are so obviously misunderstood that we venture to ask you for space for some words of explanation. Up to the date of the Brighton meeting there were, so far as was known, only seven gentlemen before the profession as candidates. Of these seven, five were heard to speak at that meeting in one capacity or another, so that many, if not most, of the members of that large assemblage had the opportunity of forming an opinion as to their fitness, in one important particular, for the honorable position to which they aspired. Two, Dr. Richardson and Dr. Glover, we believe, were not heard. Some at least of those who listened to the gentlemen in question, deemed that it was not inconsistent with the highest respect for them personally, to consider whether, from among the 17,000 practitioners of England and Wales, it might not be possible to induce a few to appeal to the suffrages of the profession who, if not better as men, should be better as representatives. No one else seemed inclined to come forward, and

the time for action was very short. The only possible way of arriving at a conclusion on what all will admit to be a most important matter was to consult gentlemen from various parts of the kingdom concerning it. This led to the summoning of the first small conference at Brighton. If the majority of those who attended it had considered that it was unlikely that any better representatives could be found, nothing further would have been done. But thinking otherwise, they resolved to take into their counsel as many as could be reached in the very short time possible to them. The number ultimately obtained was 360, from 163 different places, and nothing but want of time prevented this number from being increased ten ro twenty times. But to call these 360 gentlemen (thus without any pressure or influenec uniting themselves from such various quarters) "a small clique," is surely to employ language in a very unusual sense. The committee exercises no function beyond that of honestly to select gentlemen who in its judgment would be thoroughly able representatives; and it expects from the profession nothing more than that unbiased consideration which such an honest endeavour should secure for it. It accepting the verdict of these 360 gentlemen, we do not claim that they represent the whole profession, but, considering the number of districts represented and the decided character of the vote, it may be fairly taken as an indication of the feeling of a large body of the profession. To speak of the action of the Birmingham meeting as the action of a caucus is, again to use language in a sense which a moment's reflection must show to be incorrect. A caucus has made up its mind beforehand, and meets but to save appearances; but the thirty-five who met in Birmingham could have no possible means of knowing beforehand what were the opinions of the 360 living in all parts of the country on the names to be submitted to them, and they would not have made the experiment of a poll unless they had been honestly anxious to find this; out and the committee submits what it has done, its reasons for doing it, and its methods, with great confidence to the impartial judgment of the profession. We are, Sir, yours faithfully,

WILLIAM CARTER,
Oct. 5th, 1886. ——— HUGH R. KER.

To the Editor of THE LANCET.

SIR,—In your article in THE LANCET of October 2nd on the Direct Representation of the Profession on the General Medical Council you couple my name with that of Dr. Jacob, and say we are officials of a corporation whose representation plays already a larger part in the Council than probably any of its members. To associate Dr. Kidd or Dr. Jacob with Professor Macnamara would, you say, be a work of supererogation, and you urge the election of a genuine general practitioner to the Council instead of either of us.

Now, Sir, I beg to say that, so far as I am concerned, I am not an official of any corporation. For many years the Fellows of the College of Surgeons have done me the honour of electing me, year after year, a member of their Council. I have thereby acquired a large experience in the management of students, the control of their education, and the conduct of examinations, and I have been enabled to initiate and assist in working out improvements in the systems of education and examination which are now, I believe, universally admitted to be of a most valuable and important character. The chief and most important work of the General Medical Council is to supervise and improve medical education and examination, and thereby elevate the status of the profession and make it more useful to society, and it is because of the experience I have gained in this work through my connexion with the College of Surgeons that I have ventured to ask my professional brethren to elect me as their representative. It is, I am sure, unnecessary to remind you that the duties of the General Medical Council are strictly defined by the Act of 1858, and that they can take no cognisance whatever of anything ontside the four corners of the Act, whether it be the privileges of army medical officers, Poor-law or dispensary officers, general practitioners, or others, and that their highest duty is the supervision of medical education.

I am, Sir, yours faithfully,

Dublin, Oct. 6th, 1886. GEORGE H. KIDD.

*** We cannot say that Dr. Kidd's letter in any degree changes our opinion. Dublin physicians and surgeons have hitherto monopolised the Irish seats of the Council. No less than five do so at the present moment. For another to gain the sixth seat will be hard indeed on the practitioners of Ireland.—ED. L.

PHARYNGEAL AND LARYNGEAL "NYSTAGMUS."

To the Editor of THE LANCET.

SIR,—I am indebted to Dr. Gowers for permission to publish the following observations I have made on a patient under his care at University College Hospital. The patient, a girl aged twelve, has a cerebral tumour, and presents the symptoms of reeling gait (with a tendency to fall backwards and to one side, usually the right), vertigo, intense occipital headache, constipation, vomiting, ocular nystagmus, but no optic neuritis. The pulse is usually 100. These symptoms have been present for the last fifteen months. The ocular nystagmus is vertical and horizontal, occurs at the rate of 180 to the minute, is slightly increased in frequency during accommodation for very near, or in looking at far distant, objects. On examining the throat, I noticed the superior constrictor of the pharynx to be in a state of constant rhythmical movement in a horizontal direction, as if the posterior pharyngeal curtain were being rapidly drawn together, the twitchings occurring at the same rate as the movement of the eyes, 180 to the minute. The movement does not affect the soft palate or pillars of the fauces, the faintest possible tremor only being transmitted to them from the action of the adjacent constrictor. By pressing the point of a quill pen against the pharynx and pivoting the quill on a pin held fixed against the upper teeth, I have been able to write with the feather-end a tracing of the movement on sphygmograph paper. The laryngeal muscles are similarly affected. The arytenoid cartilages are seen rapidly gliding to and from each other synchronously with the movement of the pharynx. When the patient is breathing quietly the main movement of widening of the glottis during inspiration is interrupted by slight twitches, and similarly the movement of respiration. When the patient stops breathing the cords gradually close with five or six contractions, till they finally lie parallel and close to each other; here they remain, undergoing only a slight tremor till the patient recommences to breathe. I have had this patient under observation for over two months, and the movement has been always present. There is now a slight alteration in the state of the larynx, in that the left cord twitches more than the right, and the cords do not so nearly close when the patient stops breathing. I am not aware that a movement of this kind has been previously described, and I am anxious that it should be looked for in cases of intracranial tumour, so that its localising value may be determined. It is possible it may throw some light on the etiology of ocular nystagmus, and it may be of value to the surgeon, perhaps, in showing pressure on the medulla, and so assist in the diagnosis of the position of a cerebellar tumour. As regards the term "nystagmus" applied to the pharynx and larynx, its association and synchronism with the ocular nystagmus, and the fact that movement of the eyes in a horizontal direction is called "nodding," would seem to warrant a slight departure from strict etymological accuracy.

I am, Sir, yours truly,

HERBERT R. SPENCER, M.B., B.S. Lond.,
Oct. 1886. House Phys. Univ. Coll. Hosp.

TREATMENT BY MASSAGE.

To the Editor of THE LANCET.

SIR,—It will be a surprise and a shock to many of your readers to learn from THE LANCET of this week that the practice of massage is not to be acquired under two years, and some may even venture to ask whence the extreme elaboration of detail which this lengthened apprenticeship implies derives its sanction. It seems incredible that any manipulation of the body which human ingenuity can devise should be learnt so slowly. Divide the frame into as many departments as you will, exclude those parts which are inaccessible to massage and those which it would not venture to approach, and there remains but a limited area to which Dr. Weir Mitchell's method is applicable. Let the modes of rubbing, stroking, pinching, and kneading be multiplied to the utmost, and far beyond the reach of

language,—even then all possible contrivances will be exhausted before two years have run out. But if two years, why not ten? It may be confidently asserted that there is no digital use whatever needing two years for its acquirement that does not go on advancing towards perfection so long as the mind which informs the fingers retains its vigour. Massage takes rank with music and the Fine Arts.

To all this I venture to oppose the opinion that the manipulation of the body surface, which some call "massage," and which aims at supplying the place of voluntary muscular exercise, does not need two years to learn, nor two months, nor, with an apt scholar, two weeks. It is with massage as with other skilled exercise—as with fly-fishing and cricket and tennis. Some pick it up very readily, even from the mere observation of the skilled rubber. Some can never learn massage at all. Anyone not acquiring a fair skill after a month's training may begin to despair of ever acquiring it. It is a knack, and admits as many gradations of expertness as do the games just mentioned. But the fullest expertness is not a question of time but of natural adaptability. To suppose otherwise is to mistake both the object of massage and the nature of the faculty on the part of the teacher to which it makes appeal. These are no statements of mine, they are the substance of the teaching of many authorities, including Dr. Weir Mitchell, the original proposer of the treatment, and Dr. Playfair, who first introduced it into this country. One of the best operators at the Westminster Hospital Home for Nurses learnt it of Dr. Weir Mitchell "in a few lessons." He was so well satisfied of her expertness that he employed her on his own patients and wished her to remain in America. Her sister, whom I have just now seen, learnt of this other "in a week." Both of these sisters can quote a long list of successful cases, and their competence is attested by several well-known physicians, who have had proof of their skill. One of the earliest employers of massage in this country is the Lady Superintendent of the Home Hospital in Fitzroy-square. She has taught many; and patients needing the treatment are constantly under her supervision. The hospital has been visited by Dr. Weir Mitchell himself, who thoroughly approved of the system there in vogue. This lady believes that an apt learner can acquire massage in six lessons, while she repeats precisely what has been told me in other quarters, and especially by the matron of my own hospital (to whose kindness and interest in the matter I am much indebted) as to the wide difference between one nurse and another in picking up the trick of rubbing. From such practical testimony, let me turn to the voice of the profession. Next to Dr. Weir Mitchell, I suppose the authority of Dr. Playfair will be deemed the highest. He writes in terms which he allows me to quote, and which are sufficiently indicated by the following extracts:—"Massage is a very simple thing which has been made complex by the absurd way it has been written on abroad, and the divisions and names given to it." "Half-a-dozen lessons I consider quite enough if the learner has natural aptitude." The statement that two years are needed is manifestly absurd. "I am inclined to think that just now massage is very much overdone and often used in quite unsuitable cases." The fact is, I suspect, that massage, like other therapeutic agents that attract attention, like the hypophosphites and salicine and salicylates, is passing through its stages. First, the warm, and often indiscriminate, praise; next the statement, and doubtless the genuine belief, of some practitioners that in their own hands the new agent can be made to yield a virtue which others fail to extract from it; and, finally, the settling down of belief as to the real value of the treatment in question. And if it be so with drugs, how much more with a method of manipulation which confessedly needs skill, dexterity, and practice. Let us be content, then, to leave "massage" to make its own way like other remedies, in the full assurance that the settling day will come by and bye, when its precise value will be finally determined. And so, no doubt, in the main it will be; and in that persuasion I would gladly have spared myself a task of criticism which, in the circumstances, is exceedingly distasteful. But there are others to be considered, and it is but just that a word should be said on behalf of those to whom many of us are deeply indebted, and who may not speak for themselves. Massage is now largely resorted to: there is probably no hospital in London, and no nursing home of repute, which cannot furnish trained rubbers (as I still venture to call them) who are thoroughly competent, and whose ability is proved by the patients they have helped to cure. The time will soon come, it may be hoped, when the same may be said of every town in the kingdom. It is quite easy to disparage these quiet workers, who may be at least trusted to make no protest and no claim of their own. It is less easy to prove by results that the refinements which have been imported from the Continent add anything whatever to the virtue of Dr. Weir Mitchell's method. The treatment is still on its trial, but the facts in regard to it are in small compass and accessible to all. Massage may be so far popularised as to become a valuable help to practitioners in a class of cases heretofore singularly hopeless and pitiful, or it may ultimately fall into the hands of a few "professors," who will make of it a "speciality," or even a trade.

I am, Sir, yours obediently,

OCTAVIUS STURGES,

Oct. 4th, 1886. Senior Physician to Westminster Hospital.

"INFANT FEEDING."

To the Editor of THE LANCET.

SIR,—I regret I have not been able to reply to Dr. Marshall's letter earlier. I have received a great many communications in reference to my article on Infant Feeding, including one from the United States, showing the wide interest the subject excites in the profession.

Dr. Marshall says that "physiology and experience both negative" my plan. Surely this is putting the cart before the horse. Physiology, like other sciences, is constructed by drawing deductions from well-verified facts—it does not condemn asserted facts untested. If Dr. Marshall, and other men equally as well placed as he is, try the plan I advocate and find it fail, I will bow to their decision; but it is hard to be told that science is able to condemn it off-hand, seeing that a physiological writer has placed the average life of a physiological fact at three years! My article did not profess to treat fully the subject of milk-feeding pure and simple, so I did not give full details as to methods I have pursued in that direction. I am acquainted with "Frankland's Milk," but the process advised seems to me too complicated for universal use. Half milk and half water certainly gives a larger proportion of caseine than human milk (indeed, Dr. Meigs of Philadelphia, U.S., asserts, and to my mind proves, that the amount of caseine in human milk is certainly under 2 per cent.); but one part milk to two parts of water is, in my opinion, starvation in disguise; while adding cream and whey to water or to milk is not only a complicated process for poor ignorant people, but it involves keeping the milk for twelve hours before it is used. Considering that cow's milk has an acid reaction to begin with, while human milk is slightly alkaline, and considering how readily the milk of cows kept in sheds (and therefore fed on roots and grains) ferments, I do not think cow's milk twelve or probably fifteen hours old is likely to be as digestible as absolutely fresh milk. My own children were fed with milk from one cow; various proportions were tried of water, but all suffered severely from flatulent colic and curdy motions until the milk-and-water was thickened with a well-known food, which I believe contains bicarbonate of potash as well as malt and flour. After this the children improved in every way, and, I think, might now be shown as models of health. As regards the interval between the feedings, I have always recommended an hour and a half during the first week or two, to be gradually lengthened to two hours, whilst at some time during the night there ought to be an interval of at least four hours to give the digestive apparatus time to rest. I also always recommend that two or more bottles should be used, that at night a basin of water should be kept by the bedside, and that as soon as the child has sucked as much as it will, whatever is left is to be thrown away, and the bottle and tube placed separately in the basin of water. I still maintain that reducing the caseine "to digestible limits" is not the only problem in adapting cow's milk to infant digestions. I feel sure I am right in saying that, at all events, part of our problem is how to make the curd digestible. Mechanical effects do not seem to be sufficiently weighed, but they cannot be ignored. Take as an illustration the familiar laboratory experiment of making oxygen: black oxide of manganese helps the process, though not chemically. Again, I have read that certain savages of Patagonia of the lo[redacted] when severely pressed by

famine, mix earth with their scanty food to add to its bulk. The mechanical effect of the earth must be to allay the pangs of hunger, or they would surely never resort to such an eccentric mode of feeding.

In conclusion, I again assert, and beg of your readers to test, verify, or reject, as the case may be, my assertions, (1) that thickening one or two bottles a day of the milk and water used is quite a different thing from feeding on farinaceous food; (2) that milk-and-water so thickened is more digestible than milk-and-water alone; (3) that a diet of milk-and-water with a teaspoonful or so of farinaceous food per diem will cause a greater increase of weight, with healthy look and firm muscles, than an equal quantity of milk reduced to cream-water and whey or curdled with rennet. I am, Sir, yours faithfully,

Southborough, Tunbridge Wells. E. PAGET THURSTAN, M.D.

A NEW CULTURE MEDIUM FOR MICRO-ORGANISMS CAPABLE OF WITHSTANDING HIGH PRESSURE.

To the Editor of THE LANCET.

SIR,—Having found agar-agar, in addition to the difficulty of obtaining it, somewhat inconstant as a culture medium, I have for some little time been experimenting in the laboratory of Professor Chiene with a jelly derived from Irish moss. The jelly so obtained is much less opaque than agar, and evidently more nutritious in itself, in that some micrococci and sarcinæ are able to grow in it without the addition of any peptone or meat juice. The method of preparation is of the simplest. Two ounces of the finest selected Irish moss are macerated over night in eighteen ounces of water in a beaker; then in the morning it is placed in the steam steriliser, and kept at the boiling point of water for the period of an hour and a half, being well stirred up occasionally. At the end of this time it is strained through a flannel, or (preferably) felt bag, two or three times, when it is found to be fairly bright. As a considerable quantity of refuse matter remains in the bag, the quantity of material derived from the moss and represented in the jelly must be considerably smaller than the actual weight of moss used. The jelly so obtained will be found on cooling merely to gelatinise, and yet one finds it to withstand a temperature of 31° C. before liquefying, but if it be evaporated to ten ounces, it is found to be capable of being exposed to a temperature between 50° and 55° C. before liquefying. In this state, if a test-tube be filled with it, it is found to present the appearance of water with only a slight degree of haziness. In order to render this more nutritious, and so better fitted for the requirements of the growth of the generality of micro-organisms, I add to it the materials recommended by Dr. Klein—namely, beef peptone and ordinary cane sugar. If we add to the jelly 2 per cent. of the former and 1 per cent. of the latter, the result is a jelly almost as bright as nutrient gelatine and infinitely more so than agar, while the simple method of preparation and the price (Irish moss is about one shilling per pound) have much to recommend it.

I remain, Sir, your obedient servant,

ALEX. EDINGTON, M.B., C.M.,
Assistant to Prof. of Surgery, Edin. Univ.

Edinburgh, Sept. 28th, 1886.

GRANULOMA FUNGOIDES.

To the Editor of THE LANCET.

SIR,—As you refer in your number of Oct. 2nd to a case of this extraordinary affection described by me at the Pathological Society in May last and reported in THE LANCET, and as the disease has lately attracted a great deal of attention on the Continent, perhaps you will allow me to say a word on the most recent aspects of the subject.

The hypotheses of Drs. Hochsinger and Schiff that the disease is due to the presence of micrococci in the tissues, and that of Professor Rindfleisch, which refers it to cocci in the bloodvessels, though each has been put forward with great confidence, cannot either of them be regarded as proved. In a paper to appear in the forthcoming Transactions of the Pathological Society I have given reasons for thinking that the "cocci" of Hochsinger are not micro-organisms, but protoplasmic masses occurring in certain cells, and that the organism which Schiff cultivated from the tissues was in all probability the almost ubiquitous Staphylococcus pyogenes aureus, with which it appears entirely to agree. Professor Rindfleisch's observations are, as I have pointed out, equally open to question. There can be no doubt about their objective accuracy; but the cocci he describes would appear to be rather connected with a septicæmic process, of which his patient died, than with the original chronic disease. On the whole, then, I have ventured to conclude either that the disease is not bacterial, or that the right organism has not yet been found. My own observations (confirmed by those of several pathologists in this country) gave a negative result; and so did cultivation experiments made in the laboratory at St. Thomas's Hospital by Mr. Ballance.

I am induced to trouble you with these lines, more especially because two new memoirs have appeared on the subject since my paper was sent in. One is that of Hochsinger and Schiff, to which you refer, in which they undoubtedly describe more extensive culture experiments, but do not bring any further proof that their cultivated organisms caused the disease. The other is a paper by Professor Koebner of Berlin (*Fortschritte der Medizin*, Sept. 1st), where the bacterial theory of this disease is combated by arguments which are almost identical with those used by me in the Pathological Transactions, and are founded on observations entirely agreeing with ours in this country as regards the absence of micro-organisms. These views were, I have just heard, brought forward at the late Medical Congress at Berlin, and were substantially confirmed by Neisser. The Berlin observations were evidently as independent of mine as mine of them, so that their coincidence is a valuable mutual confirmation. The same, I cannot but expect, will be the result of the investigation of other cases of the same disease, which may from time to time occur, unless, indeed, some day the not-impossible bacillus should be detected. In the meantime the moral is that of the immortal cookery-book "First catch your hare."

I am, Sir, your obedient servant,

Wimpole-street, Oct. 4th, 1886. J. F. PAYNE.

THE TREATMENT OF CASES OF OPERATION FOR CATARACT.

To the Editor of THE LANCET.

SIR,—Mr. Snell's paper on the treatment of cataract, published in your issue of the 18th inst., leads me to suppose that the following method of dressing, which I have used in nearly all my cataract operations and iridectomies for several years, may be new to some of your readers. Strips of salicylated isinglass plaster are cut two inches and a half long and rather more than an eighth of an inch wide. As soon as the operation is completed and the lids closed, a strip is damped by drawing it over a pad of Gamgee tissue dipped in warm water, and is then applied along the margin of the upper eyelid so as to reach from the bridge of the nose to beyond the outer canthus; another is applied parallel to the first along the edge of the lower lid, and a third at right angles to the other two, reaching from above the eyebrow to the cheek. Care must be taken to make this strip stick firmly to the other two, and this is easily managed if it is damped to the proper degree. The eye not operated on is secured in the same manner, or sometimes the strip on the lower lid is omitted. In a few minutes the plasters are dry, and no further dressing of any kind is needed. By this means the eyelids are kept immovable without any pressure; any swelling which may occur is at once visible; the discharge has free exit between the edges of the lids, and can be removed by a sponge or pad of wet cotton-wool without disturbing the dressings. The salicylic acid in the plaster acts to some extent as an antiseptic. I have never had any trouble from the plasters loosening by the discharge and allowing the eye to open. Occasionally the ends of the plasters curl up a little, but this is easily remedied by damping them down again. Usually about the fourth day the plaster is softened by laying a pad of wet Gamgee tissue over the eye for a few minutes, and then removed and a similar dressing applied. I know of no drawback to the method, and confidently recommend a trial of it by your readers.

I am, Sir, yours obediently,

York, Sept. 27th, 1886. TEMPEST ANDERSON, M.D.

THE FIRST PROFESSIONAL EXAMINATION IN SCOTLAND.

To the Editor of THE LANCET.

SIR,—Will you permit me very briefly to reply to "M.D. Glasgow," who writes in your issue of the 2nd inst. regarding the first professional examination in Scotland? Your correspondent speaks of the student being confronted with chemistry, botany, and natural history (i.e., zoology) after passing his preliminary trial. He alludes to the "width" of these sciences, and, by implication, would have us believe that the medical student is forced to become little short of a specialist in each. I cannot speak either for Edinburgh or for Aberdeen, but as I have held the position of examiner in botany and zoology in the University of Glasgow for ten years past, I may be credited with a very fair knowledge of the amount of biological information the Glasgow student is required to possess for success in passing his first professional examination. Chemistry I leave out of consideration, for although "M.D. Glasgow" apparently includes this subject in his sweeping assertions, I do not think any sane person would dream of maintaining that a medical student should be otherwise than a fairly competent chemist. As regards botany and zoology I assert, without fear of any contradiction worthy the name, that at Glasgow University any student who shows a fair, and by no means necessarily minute, acquaintance with the broad facts of these sciences is certain to satisfy the examining board. We do not look for the *minutiæ* of biology from medical students, but we do expect them to possess what hundreds of students yearly do contrive to acquire—namely, a broad acquaintance with the fields of animal and plant life. I am at a loss to understand the mental calibre of the student's your correspondent speaks of as having again and again been "plucked" in their first professional examination, save, indeed, on the theory that there are certainly a proportion of students who will not take the trouble to acquire even the reasonably limited knowledge needed to pass. My experience as an examiner and I will add as a teacher of biology also is that a certain class of students never will pass the first professional or any other examination whatever. These are the unhappy few who think themselves hardly used, because when, for example, they have informed examiners that a fern is a dicotyledon, or that a crab is a vertebrate animal, the said examiners refuse to credit them with the knowledge necessary to pass even the simplest of trials. Add to this that the intellectual demands made upon medical men nowadays are of very heavy character, and that the doctor is expected to be at least as intelligent a man as the schoolmaster or the clergyman; and I fancy "M.D. Glasgow" must admit that a knowledge of biology—possessing as it does intimate bearings on the nature and cure of disease—is by no means the least valuable of the mental furnishings of the modern physician. I am, Sir, yours obediently,

Edinburgh Medical School, Oct. 2nd, 1886. ANDREW WILSON.

THE MEETING OF GERMAN NATURALISTS AND MEDICAL MEN IN BERLIN.

(From a Correspondent.)

THE fifty-ninth meeting of the Society of German Naturalists and Physicians (corresponding to the combined British Association and British Medical Association), which has just taken place in Berlin, has been one of the most brilliant gatherings of the kind, both as regards the attendance and the scientific outcome. The scientific work at these meetings consists in the delivery of lectures of general interest before the whole assembly on days set apart for the purpose, in the reading of papers, and in demonstrations in the different sections.

As specialism exists in Germany to a greater degree than in England, the number of sections at these gatherings is very large, and this year there were thirty sections, of which twenty-one were more or less medical. In spite of the subdivision of the work (thus I noticed a section on pharmacology, one on pharmacy, one on general hygiene, one on military sanitary science, and one on medical geography, climatology, and hygiene in the tropics), all the sections were well attended, and some had as many as 400 members. The different hospitals, scientific institutes, and museums were also thrown open for inspection, and in some special demonstrations were given. There was also held in connexion with the Congress an exhibition of drugs and scientific instruments used in the different branches of medicine and the natural sciences.

Deferring for the present an account of the work done in the sections, and of the exhibition of instruments, I wish, to-day, briefly to notice some of the general addresses. At the first open meeting Professor Virchow gave the introductory address, in which he briefly sketched the origin of the Association, its aims and objects, and its immense development, and alluded to the scientific activity of the German race as a guarantee for the growth of the German nation. "In the severe struggle for existence only those nations will survive which succeed in unravelling the mysteries of nature in new directions, and in placing at the service of man the forces which we find spread out in the world in a profuse manner." He then alluded to the connexion of the natural sciences with medicine, which connexion was still kept up by the German Association, in contradistinction to its English sister Association, and dwelt at length on the new method, the mechanical method, of research (in the sense in which Leibnitz uses the words, "Omnia in corporibus mechanice explicari posse"), which, by replacing the so-called natural philosophy (*Naturphilosophie*) and speculative philosophy, remodelled the whole of biology, and gave the basis to all scientific inquiries. Darwin, in his famous work on the Origin of Species, tried to solve the question of descent, not in the sense of the old natural philosophy; he did not discuss general probabilities, but looked for the several practical cases; he did not search for special organic powers, but tried to find the mechanical effect of natural causes. The same method has been pursued ever since; and if in recent years rapid advances have been made, especially in the study of infectious diseases, the aim and the method have remained the same—the scope only of our investigations has been altered. "Our modern transactions are characterised by the spirit of empirical but methodical investigation, the spirit of practical synthesis, the spirit of brotherly co-operation in the several branches of the wide scientific field."

Dr. W. Siemens gave an able address on our Scientific Age, and was followed by Professor Bardeleben of Jena with a paper on "Hand and Foot," in which he compared the hand with the foot on the basis of comparative-anatomical and palæontological data. He then discussed the origin of the vertebrate limbs, and contrasted Gegenbaur's theory with the more recent one of Thacher, further developed by Mivart and the lamented Balfour, concluding with a number of aphorisms more suitable for the lay portion of the audience—such, for instance, as the adaptation of the terms "foot" and "hand" to such various purposes as standards of measurement, as the basis of our numerial system, and so on.

At the second general meeting Professor Cohn (Breslau) read a most fascinating paper on "Questions of Life" (*Lebensfragen*), which showed that the great problem is not yet solved, and that in the living organism there are forces which, though they must be mechanical, as they put bodies in motion, yet cannot be split up into components of atomic molecular forces. "The gulf which separates life from death, organic from inorganic bodies, is not closed, and none of our hypotheses will help us to bridge this gulf." He was followed by Dr. Schweinfurth with a paper on a geographical subject, and by Professor Ilis on the "Development of the Zoological Station at Naples and the growing necessity for Scientific Central Stations." The lecturer dwelt on the advantages such institutions, if properly worked, would have for the study of many questions of physiology and embryology. In these institutions collective investigation on some subjects—as, for instance, the finer structure of the brain—could be carried out—work which could not be done by a single individual. They should form a sort of library or museum, accessible to all scientific inquirers.

Professor Stricker (Vienna) then gave a demonstration with his powerful electric microscope, and showed how useful the instrument is for lecture purposes.

At the third and last general meeting there were three addresses, only one of which, that of Professor Bergmann of Berlin, was of medical interest. Professor Bergmann spoke

of the relations of modern surgery to internal medicine, the triumph of surgery due to the antiseptic method of Lister, and the scientific development of surgery. Wounds can now be made to heal so readily that surgery has invaded the territory of medicine, and serious operations on internal organs are performed, and often, also, operations merely for the purposes of diagnosis. Internal medicine, occupying itself largely with those disease-germs which are brought to the organism from without, tries to wage war against these germs in their native elements—the air, water, and soil,—and is becoming more and more preventive.

I propose in a future communication to allude to the work done in some of the sections, and to some other matters in connexion with the Congress.

LIVERPOOL.

(From our own Correspondent.)

OPENING OF THE LIVERPOOL UNIVERSITY COLLEGE.

The formal opening of the Winter Session of the University College, Liverpool, was held at St. George's Hall, on Saturday last, under the presidency of Lord Derby. In opening the proceedings, the noble chairman said he believed it was no exaggeration to say that "the record for the year just ended is satisfactory in nearly every respect. No previous session has shown so marked an increase either in the number of students or the amount of fees. The chief event of the year is the completion and opening of the new chemical laboratory, which was inaugurated by an address from Sir Lyon Playfair in March last. The Council since that date have had six months' experience of the working of the arrangements then completed, and no serious defect or oversight had been discovered, those who are best qualified to judge considering the laboratories as equal for completeness and efficiency to any now existing in the British islands. Another matter has engaged a good deal of public attention. Two years ago, acting on a strongly expressed public feeling, the Senate devised a two years' course of study suitable to young men who were training themselves for a business life. The scheme was discussed over and over again; many of the leading firms in Liverpool were consulted; it was adopted by the governors in the autumn of last year, and no pains have been spared to obtain for it the approval and support of the principal trade associations of the city, which support has been given in a simple and very practical form. Most of the leading banks and insurance companies and above 350 private firms have agreed to recognise the certificates granted by the College to those who pass creditably through the proposed course—not, of course, as an absolute claim to employment, but as a recommendation to which they attach importance; and in many cases they will lessen by one year the ordinary term of apprenticeship in favour of candidates who may be so qualified—which is a kind of help doubly valuable, both because it furnishes a practical inducement to young men to go through this course, and because it shows an amount of sympathy among business men with the work which the College is doing, which strengthens our hands in appealing to the public for further help. Mr. G. Holt, already a large donor, has very liberally presented to the College the sum of £2000 for the advancement of medical study, and that sum has been applied to the creation of two scholarships to be annually awarded to senior students of the medical school. And an entirely novel experiment has been tried in the establishment of ten very small scholarships for working men, yielding only £5 each, but involving, on the other hand, the necessity of attendance at two courses only of evening lectures. The object of them is to assist men not otherwise able to provide the cost of attending lectures and of the necessary materials for study. The Council is asked to do this, that, and the other, which is useful and desirable, and tries to meet the wants and wishes of the public; but does so, for the most part, at a heavy increase of expense. It is a good sign—a healthy sign—that the child should be outgrowing its clothes, but the parents must not complain if they have to pay for new ones. The College has grown very fast, and no men hereafter will ever venture to say again, what was said by many people a few years ago, that such an institution is not wanted or appreciated in Liverpool. 'Well begun is half done'; and the severest critics cannot deny that the beginning has been a good one." An introductory address was then delivered by Mr. Wm. Martin Conway, the Professor of Art, who selected as his subject "The Succession of Ideals." Lord Derby afterwards distributed the prizes to the successful candidates, and after votes of thanks had been proposed and carried to the lecturer and Lord Derby, both of whom briefly returned thanks, the proceedings terminated. The annual dinner was held the same evening in the Adelphi Hotel, under the presidency of Dr. Caton, at which a large number of medical practitioners were present.

"VIEWING" REMAINS.

Referring to the remarks in THE LANCET of last week under this heading, there is another phase of the subject which ought not to be ignored. A most experienced coroner's officer in this city, now retired, gave, among other experiences, this: that many a man dates the commencement of a career of intemperance to his first serving as a coroner's juror, and the effects upon him of "viewing" the body. In hot weather especially, the state of a body within twenty-four hours after death may be such as to try severely even those who are accustomed to such sights and odours—a condition which is intensified by the fact that the "viewing" cannot, as a rule, be until two or even three days after death, and frequently even longer than this. In Shanghai the coroner's jury comprises three persons; a county court jury in this country, five. If the coroner's jury is a desirable institution to perpetuate, might it not be reduced? And seeing what an utter farce the "viewing" is, it is high time it was dispensed with.

PREVENTION OF CRUELTY TO CHILDREN.

A summary of the work done during the month of September by the Society for the Prevention of Cruelty to Children amply justifies its formation. In that interval of thirty days the Society took up 58 new and 10 old cases, the former involving the welfare of 107 and the latter that of 12 children. Among the complaints were 2 of assault, 1 of excessive beating, 11 of general neglect, 2 of starvation; exposure, 21; sleeping out at night, 6; the remainder being cases of begging and of selling at night. In four cases the complaints were dismissed. Two children were committed to industrial schools, 36 were under the supervision of the School Board, 3 were placed in workhouse schools, 2 in hospitals, 3 with relations, and 22 with parents under visitation; 29 parents were cautioned; the remainder of the cases were disposed of in various ways.

HARVEST FESTIVAL AT THE ROYAL INFIRMARY CHAPEL.

On Sunday last the usual harvest festival was held in the chapel of the Royal Infirmary. The decorations, which were by the lady superintendents and their assistants, were very beautiful. The musical portion of the services was most ably rendered by the large staff of nurses and probationers, who, under the indefatigable organist, spare no effort in making the services every Sunday as cheerful as the surroundings of a hospital chapel will allow. The chapel was filled to overflowing, and Archdeacon Bardsley preached on behalf of the Samaritan Fund of the infirmary. This fund enables the chaplain (the Rev. W. Smith) not only to give some little help to poor patients, but also in many instances to alleviate the distress at a patient's house while the bread-winner is the inmate of a hospital ward. The offerings at the two services amounted to £7 9*s.* 1*d.*

UNIVERSITY COLLEGE, LIVERPOOL: MEDICAL FACULTY.

List of Scholarships, Exhibitions, Prizes, &c., 1885 to 1886: Scholarships and Prizes: Holt Tutorial Scholarships, A. W. Collins and J. E. Gemmel. Lyon Jones Scholarships, H. A. Burrowes, S. R. Knight (resigned), and A. J. Chalmers. Derby Exhibition: W. T. Thomas. Winter Session.—Third and fourth year subjects: Medicine: W. T. Thomas, silver medal. Surgery: W. T. Thomas, silver medal. Pathology: J. H. Abram, silver medal. Obstetrics: F. Kerans, silver medal. Second-year subjects: Advanced Anatomy and Physiology: E. Hale, Torr gold medal; J. Gould, bronze medal. First-year subjects: Elementary Anatomy and Physiology and Chemistry: R. H. Carlisle, Bligh gold medal; J. S. Sewill, bronze medal. Summer Session.—Materia Medica: J. Cunningham, silver medal. Botany: A. J. Chalmers, silver medal. Medical Jurisprudence and Toxicology: F. Kerans, silver medal. Practical Chemistry: A. C. Wilson, silver medal. Histology Prizes: First, Mr.

Hale; second, Mr. Grimsdale. Students' Debating Society Prizes: First prize for essay, Mr. Sanderson; second, Mr. Livsey. First prize for debating, Mr. Capper; second, Mr. Fox-Parry. First prize for specimens, Mr. Garth; second, Mr. Buchanan. Prize for medical cases, Mr. Abram; for surgical cases, Mr. C. W. Graham; for venereal cases, Mr. Leigh.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

WORK is being resumed for the winter session in most of the departments during the present week. In the arts, science, and law departments the Professor of Mathematics delivers an "introductory," and in the evening classes department an introductory address will also be delivered on Monday next; but, in accordance with the now established custom, the medicals will have no such opportunity of giving vent to the exuberance of their animal spirits, but, in lieu thereof, a conversazione was held last night in the College, which was very largely attended, between 400 and 500 visitors being present. The whole of the buildings were thrown open, and various scientific apparatus, &c., were shown for the instruction and amusement of the guests. The Dean of the medical school (Professor Young) gave his report of the work of the past year, and afterwards delivered an address on the future prospects of the College and University. Later on, Dr. Dreschfeld discoursed to a large audience on Pasteur and his inoculation method for the prevention of hydrophobia. On Thursday evening the annual medical dinner of the College will take place at the Queen's Hotel, under the presidency of Sir William Roberts.

HOSPITAL EXTENSION.

With a view to assist in raising the funds required for the proposed extension or rebuilding of St. Mary's Hospital, which has for some time past been in contemplation, steps have been taken for holding a bazaar next month in the Gentlemen's Concert Hall. The additions to the Hospital for Consumption by the erection of a new and more suitable building for the out-patient department are rapidly approaching completion; it forms a very compact and well-adapted building for the purposes required, and will be a great improvement on the make-shift accommodation hitherto provided in John-street. Twelve months ago, the committee of the Northern Counties Hospital for Incurables appealed to the public for the means to extend their hospital at Mauldeth Hall, as it had become quite full and many applications for admission had to be refused. As the result of this, a most handsome gift was received from a lady, Miss Kay, in the shape of a large house and grounds near Bury. These, having been taken over and adapted by the committee, were recently formally opened by the Bishop of Manchester. The accommodation here will ultimately provide for some forty additional patients, and will, for the present at least, render the extension of the original building unnecessary.

MILK ADULTERATION.

Our municipal authorities are still very vigorous in the prosecution of offending milk-sellers. Scarcely a week passes but we hear of cases in the police-court; and letters have not been wanting in the columns of the daily press, complaining that the milkmen are in some cases scarcely treated with fairness, and a vigorous defence was made in a recent case by counsel, to show that a milk containing only 8·3 of non-fatty solids was not necessarily a sophisticated one; but the magistrates were not to be moved, and convicted the offenders of wilfully tampering with the quality of the milk.

SANITARY PROGRESS.

The large tract of land at Carrington Moss, which came into the possession of the Corporation for the purpose of being utilised as a means for disposal of the refuse and night soil of the southern part of the city, is being rapidly prepared for this purpose, and commendable activity has been shown by the health department in the progress of this work. Another useful step recently taken by the Parks Committee of the Corporation is the acquisition of a portion of the brick fields at Rusholme, for a public recreation ground. The Open Spaces Committee, so ably presided over by Mr. Herbert Philips, has had much to do with this desirable object being brought about.

Our medical societies have commenced their work again, and at a meeting of the Owens College Medical Society, it was resolved to discontinue the use of the central room, &c., which was last year provided in the centre of the city, in deference to the views of some of the members that the college rooms were too far away from the centre of the town. The experiment has, however, shown that members prefer to go to the library and reading-room at headquarters—the central room having scarcely been used at all.

Manchester, Oct. 6th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

BERWICK.

THE bazaar in aid of the Bethnal-green Free Hospital was opened in this ancient border town on Wednesday last by H.R.H. the Duchess of Teck. The ceremony was regarded in the light of "an event" at Berwick, and was well attended. The bazaar was kept open two days, closing on Thursday night, and the result was a gain of over £500 for the charity.

INFANTILE DIARRHŒA.

Dr. Renton, medical officer of health at Chester-le-street, Durham, in his report to the sanitary authority for the past month, thus refers to the prevalence of infantile diarrhœa in the district: "I find that diarrhœa, always our anticipated scourge at this period of the year, has been the cause of fourteen deaths; the whole of these fourteen deaths have occurred in infancy or early childhood, and I have no doubt that improper feeding has been the initial factor in each instance. It is noticed that amongst the greater number of the working classes very crude notions exist as to the proper nursing of those of tender years, and, what is still more to be deplored, they will not be taught, or they turn a deaf ear to the warning of the doctor. Thus, either from ignorance or wanton carelessness, the death-roll is generally swelled in the autumn months."

THE NEW HOSPITAL FOR JARROW.

The foundation-stone of the new hospital at Jarrow was laid last week. The site was well chosen, with good drainage, and is at a considerable distance from any dwelling—a matter of importance in a hospital intended as this is for infectious diseases. A brick wall is to be built round the site 9 ft. high, with pillars about 14 ft. apart. The administrative department will be two storeys high. On the ground floor will be the doctor's and matron's rooms, the kitchen, and dispensary, with scullery and pantry in the rear; while on the first floor will be bedrooms and baths. The ward block is to be 118 ft. long, and will consist of four wards, two nurses' rooms, and two bath-rooms. There will be two wards for females, entered from the south side of the building, and with accommodation for seven beds. The men's wards will be entered from the north side, and will have accommodation for six beds, with nurse's room, bath-room, &c. The sanitary and disinfectant block will be situated at the east part of the site, and will be fitted with washing appliances for thirty-nine patients. The building will be of brick with stone facings, and is estimated to cost £3107. This does not include the cost of the site, which was £500.

DR. J. G. HOUSEMAN OF NEWCASTLE.

Dr. J. G. Houseman has resigned his appointments at the Children's Hospital, the Eye Infirmary, the Throat and Ear Hospital, &c. He has determined to travel for a lengthened period—proceeding, I believe, in the first instance to China. Dr. Houseman has many friends in Newcastle and the north of England, and he will carry with him in his travels their best wishes for his health and welfare.

DEATH FROM LEAD POISONING.

An inquest was held here this week on another of these unfortunate cases, sadly too frequent amongst female white-lead workers. She was a married woman, aged thirty-four, and up to the time of her commencing employment at the

lead works had good health. In a very short time, however, she became subject to the poisonous influence of the lead, had convulsions and colic, followed by the usual train of symptoms, ending in death. The coroner, in summing up, said it would be a great advantage to the people employed at lead works if something could be invented to render their labour less dangerous. He was afraid, however, that the precautions which had been already brought into use were not resorted to as much as they ought to be by those who had to work in lead factories.

Newcastle-on-Tyne, Oct. 4th.

IRELAND.

(From our own Correspondent.)

QUEEN'S COLLEGE, CORK: THE MEDICAL SCHOOL.

The President, in his report just issued for the past session refers to his previous report, in which he dwelt upon the advisability of enlarging the scope of the teaching in the medical school, so as to enable it to perform efficiently the increased work imposed upon it, in consequence of the rapid growth of medical science, and the gradual enlargement of the medical curriculum of the Royal University. For this purpose he suggested the teaching of physiology, separated from that of anatomy, and the establishment of a special chair of physiology. He also recommended the establishment of two new chairs, one of human and comparative pathology, and the other of public health, including medical jurisprudence. The proposed enlargement of the scope of teaching in the Medical Faculty suggests the necessity of likewise improving the clinical teaching in the Cork hospitals, as any efforts to bring the teaching at the College up to the present level of medical science must remain almost fruitless without the thorough co-operation of the hospitals. The materials for practical teaching in the general and special hospitals, if the Union Hospital is included, which is now open to students, are very good, and the president suggests that the staffs of all the hospitals in Cork should unite for teaching purposes, classify the students who attend the Cork School of Medicine, and so arrange their clinical teaching that everyone might be able to get the full benefit of it. Under such an organisation the time of both teacher and student would be much economised; while better provision than now exists could be made for teaching junior students. At present these form part of the helpless crowd of young men, who, with a nucleus of real working students, follow the physician or surgeon from ward to ward, and who, lacking systematic preliminary knowledge of disease, are unable to benefit by the clinical teaching suited for the advanced students. Again, the staff of the larger hospitals should be increased by a number of assistant physicians and surgeons, who should conduct, under the direction of the senior members of the staff, a large part of the clinical teaching. In this way there would be formed a body of competent candidates accustomed to teach, and likely to keep themselves in the current of medical science, from whom to select persons to fill such vacancies as would from time to time occur in the staff. Clinical clerkships and dresserships also should be established, these important offices being given after a practical examination by examiners appointed by the associated hospital staffs, and a certificate given to each student at the end of his term of office.

ROYAL UNIVERSITY OF IRELAND.

Earl Dufferin has been selected to succeed the late Duke of Abercorn as Chancellor of this University. The election for a member of the Senate will take place towards the end of this month, when a very exciting contest may be expected.

NATIONAL ORTHOPÆDIC AND CHILDREN'S HOSPITAL, DUBLIN.

The committee of this hospital, having determined to move into larger and more commodious premises, have decided to issue an appeal for the necessary funds to enable them to secure a larger building and furnish the same up to all the modern requirements of a children's hospital. The institution is a deserving one, and it is sincerely to be hoped that the amount required may speedily be subscribed.

Dublin, Oct. 6th.

PARIS.

(From our own Correspondent.)

M. POLAILLON'S GASTROSTOMY CASE.

AT the meeting of the Academy of Medicine last week, M. Polaillon exhibited the patient on whom he had performed the operation of gastrostomy for the removal of a fork from the stomach, and to which you referred in an annotation in THE LANCET of September 25th. The operation has been most successful in all respects. The patient has remained quite well and hearty, and when presented he held in his hand the fork that he had swallowed. There was no symptom whatever of peritonitis, but immediately after the operation he was seized with jaundice, which lasted a few days. This was followed by a small abscess, which opened at the inferior part of the wound, but soon healed. No other untoward symptom occurred, and at the end of three weeks after the operation the man was able to get up and go about the garden of the hospital. There is evidently no adhesion between the incision of the stomach and that of the abdominal parietes, as that organ can be felt moving freely in the peritoneal cavity. The "suture perdue" was therefore a complete success, and reflects great credit on M. Polaillon, who performed the operation, and who was the first to employ this form of suture in such cases.

CYSTICERCI IN MUTTON.

M. Johannès Chatin, the newly-elected member and son of Professor Chatin, then ascended the tribune, and read a paper on "Ladrerie" in sheep. Up till now the flesh of sheep was considered, when eaten in a raw state, to be as dangerous as pork and beef, owing to the presence of cysticerci in the muscular tissue. According to M. Chatin, however, there is nothing to be apprehended in eating mutton raw, as, although the presence of cysticerci has been established in the flesh of sheep, they are never found in such numbers as to determine a veritable "ladrerie," and, as they do not attain the development of the cysticerci of pigs and oxen, there is no danger of their transmission to the human species. M. Chatin therefore concludes that mutton in its raw state may be safely prescribed whenever such a form of treatment is indicated.

ABNORMAL PNEUMONIA.

Dr. Netter of Nancy related a case at the Congress recently held at that town of an individual with a palustral diathesis, who was suddenly seized with pneumonia, most probably of the same origin, for instead of following its ordinary course the malady presented a certain intermittence. Sulphate of quinine was prescribed by way of trial, and a few days afterwards the patient was cured. The author thinks that in cases of abnormal pneumonia it would be useful to examine the patient, not only morning and evening, but several times during the day, as any slight remission might pass away unperceived. If Dr. Netter had not examined his patient during the febrile remission, he would not have recognised the particular nature of the affection.

Paris, Oct. 5th.

THE SERVICES.

ADMIRALTY. — The following appointments have been made: —Staff Surgeon James Dunlop, to the *Egeria;* Surgeon Alexander F. Harper, to the *Algerine;* Surgeon Howard J. C. Todd, to the *Ganges;* Surgeon A. S. Nance, to the *Swallow;* and Deputy Inspector-General Francis W. Davies, to Jamaica Hospital.

RIFLE VOLUNTEERS.—1st Wiltshire: The following Surgeons are granted the honorary rank of Surgeon-Major:—G.C. Taylor, M.B., and F. F. Lee.

SCARLET FEVER EPIDEMIC IN DUNDEE.—No less than 263 fresh cases of scarlet fever were reported to the sanitary authorities of Dundee during the month of September. They have occurred principally in the more crowded parts of the town, although no district has been entirely free of the epidemic.

Obituary.

ENRICO MARZARI.

PADUA has suffered severely in these days, not only from cholera and small-pox, but from the loss of distinguished practitioners who have worn their lives out in combating the two epidemics. As if the death of the eminent surgeon and clinical teacher, Professor Francesco Marzolo, were not sufficient, she has now to mourn that of his favourite pupil, Dr. Enrico Marzari. After a highly creditable curriculum at the University of Padua, Marzari became Professor Marzolo's assistant, and under the rigidly scientific and largely benevolent auspices of that able consultant he made himself known and esteemed by the profession and the public. He then took his degree of "In Medicina Doctor," with special honours for practical as well as theoretical proficiency, and at once embarked on his professional career. He was making rapid progress, accelerated by the premature decease of his patron and teacher Marzolo, to whose *clientèle* he succeeded, when symptoms of cardiac mischief, hereditary in his family, began to show themselves. He struggled on, however, and for two years continued in his daily widening path, in spite of warnings that would have been final with a less intrepid nature. The epidemic of small-pox gave him much to do among the less-favoured classes, who never appealed to his benevolence in vain, and he was barely recovering from the effects of over-exertion thus induced when the cholera epidemic assumed alarming proportions. Again Marzari was at the front, but this time with sadly diminished strength. Spasmodic pain of an aggravated kind was rapidly making life a burden to him, when on the 30th ult. he almost suddenly expired. A Paduan correspondent writes: "He falls a victim to zeal and duty. The sad announcement was received as something personal, not only by a wide circle of friends and admirers, but by a still wider circle of the poor, to whom he was for years an unwearied benefactor. To his family he bequeathes no other wealth than that of a name honoured and cherished by all his fellow-citizens. His funeral was a touching spectacle; every rank and calling was represented at his grave; and the populations of San Leonardo and Savonarola, on whom most of his gratuitous attendance was lavished, closed their shops and draped their houses in black, as a token of their sense of loss."

JOHN PEARSON BELL, M.D.

DR. J. PEARSON BELL, whose death occurred on the 26th ult. at his residence in Hull, received his professional education at St. Thomas's Hospital and the University of Glasgow. In 1830 he became a licentiate of the Society of Apothecaries of London; in 1845 he obtained the degree of M.D. and C.M. at Glasgow University, and in 1860 the licence of the Royal College of Physicians of Edinburgh. At the time of his death the deceased was in his seventy-eighth year, and had for many years been connected with most of the public institutions, and taken part in the principal public movement in Hull. In 1875 he was appointed a magistrate of the borough, and for over fifty years he had a long and prominent career as a Freemason. In April last Dr. Bell's golden wedding was celebrated, when the Masonic brotherhood throughout the province showed their appreciation of his services by presenting to Mrs. Bell a marble bust of her husband. Dr. Bell was highly esteemed in Hull, and his death is much regretted by the inhabitants of that town.

THE PUBLIC HEALTH ACT IN SCOTLAND.—On the 1st ult. a man was fined five shillings at Greenock for removing by railway his daughter who was suffering from scarlet fever.—At Dundee, on the 23rd ult., a lodging-house keeper was fined half-a-guinea for neglecting to ascertain whether one of his lodgers was suffering from infectious disease.—On the 21st ult., at the same police-court, a woman who was charged with a similar offence was dismissed with a caution.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 30th ult.:—

Barrett, Ernest, Elm-road, Dulwich.
Horner, Charles Julian, M.R.C.S., Fern-hill, Walthamstow.
Sibley, Walter Knowsley, Harley-street.
Stevenson, George, Edgware-road.

THE new building in connexion with the out-patient department at Westminster Hospital was opened on the 5th inst.

ON the 28th ult., a deputation from the Royal Commission for the Blind, Deaf and Dumb, Imbecile, &c., visited the Royal Albert Asylum.

DAVOS PLATZ.—This popular health-resort is to have the advantage of railway communication from Landquart. The line will be twenty-five miles in length, and will traverse Prättigau.

ENTERIC FEVER AT SWANSEA.—Enteric fever is again prevalent at Swansea, the outbreak being attributed to the access of farm refuse to a stream which runs into a reservoir which supplies the west end of the town.

MISS FLORENCE NIGHTINGALE has been compelled through illness to decline to unveil the statue of Sister Dora at Walsall on the 11th inst.; Mr. Gladstone also has expressed his regret at being unable to attend the ceremony.

AN inquest was held at Bangor in the north of Ireland on the 28th ult., on the bodies of two women whose death had been produced by irritant poisoning, caused by their having partaken of putrescent german sausage.

SCARLET FEVER IN OLDHAM.—At a special meeting of the Sanitary Committee of the borough of Oldham on the 4th inst., the medical officer reported that there had been within the last few days a large increase in the number of patients in Westhulme Infirmary. The cases are nearly all scarlet fever.

AT the meeting of the Liverpool City Council on the 6th inst., the medical officer of health recommended that, in consequence of the prevalence of scarlet fever in the city, additional hospital accommodation should be provided. After a lengthened debate, the matter was referred to the Special Hospitals Committee.

SHEFFIELD MEDICAL SCHOOL.—The Mayor of Sheffield has announced his intention of calling a public meeting to promote the erection of a new School of Medicine in the town, the premises now occupied, and which were built in 1828, not being equal to the present requirements of the institution. A handsome sum of money has already been subscribed, but £2000 more is required. The Archbishop of York has consented to take part in the meeting, and Sir Andrew Clark has promised to visit Sheffield to speak at the gathering.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The following office-bearers have been elected for the ensuing session: President: Dr. Alderson. Vice-Presidents: Mr. E. C. Barnes, Dr. Campbell Pope, Mr. Hemming, and Mr. Keetley. Council: Mr. Swinford Edwards, Dr. Hart Vinen, Mr. R. F. Benham, Dr. Owles, Dr. Thudichum, Dr. Bullock, Dr. Wells, Dr. Pickett, Mr. Gunton Alderton, Mr. Lloyd, Dr. Spicer, and Dr. Savill. Treasurer: Mr. F. Lawrance. Secretaries: Mr. H. Percy Dunn and Dr. Clippingdale. Auditors: Dr. Blenkinsop and Dr. Gloster.

WARNEFORD HOSPITAL.—At a special meeting of the governors of this institution held at Leamington on the 6th inst., it was proposed that, as at the Queen's Hospital, Birmingham, every out-patient should be required to pay a registration fee of one shilling. The honorary medical staff objected strenuously to the proposal, and it was urged that when all the attendant expenses had been defrayed the hospital would not benefit pecuniarily to the extent of £50. The plan was eventually rejected by an overwhelming majority, only three voting for it.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ANDERSON, JAMES, M.D., M.R.C.P., has been appointed Assistant Physician to the London Hospital.

BUTLER, W. HARRIS, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for East Woolwich.

COLLINGWOOD, FREDERICK W., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant House-Surgeon to the Torbay Hospital, Torquay.

CUSSE, ERNEST, M.R.C.S., L.S.A., has been appointed Resident Medical Officer and Secretary to the Bournemouth Cottage Hospital and Dispensary, vice T. G. Pigrott, M.R.C.S., L.R.C.P.Lond., resigned.

DOVE, AUGUSTUS CHARLES, M.B., M.R.C.S., has been appointed Junior House-Surgeon to the Cancer Hospital, Brompton.

GUTHRIE, LEONARD L., M.A., M.R.C.S., L.S.A., has been appointed House-Surgeon to Paddington-green Children's Hospital, vice Dr. George Parker.

HASLEWOOD, ALBERT, M.R.C.S., has been appointed Honorary Medical Officer to the Devonshire Hospital, vice W. H. Flint, L.R.C.P., resigned.

PARROTT, THOMAS GODFREY, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the National Sanatorium for Consumption and Diseases of the Chest, Bournemouth, vice Dr. Humby, resigned.

WELSFORD, GEORGE FREDERIC, M.B.Cantab., M.R.C.S., has been appointed Medical Officer for the Second District of the Woodstock Union.

Births, Marriages, and Deaths.

BIRTHS.

ARNOTT.—On the 3rd inst., at Burnswark, Malabar-hill, Bombay, the wife of Surgeon-Major James Arnott, M.D., of a son.

BATTYE.—On the 27th ult., at Denbigh-street, the wife of John Howard Battye, M.D., of a son.

COHEN.—On the 2nd inst., at Stranraer-place, Malda-vale, W., the wife of A. Cohen, M.A., M.D., of a daughter.

CONSTABLE.—On the 29th ult., at Kennington-park-road, the wife of Joseph J. Caffry Constable, M.D., of a daughter.

DALE.—On the 24th ult., at Park Lea, Scarborough, the wife of Frederic Dale, M.D.Cantab., F.R.C.S.Eng., of a son.

DUKES.—On the 1st inst., at Sunnyside, Rugby, the wife of Clement Dukes, M.D.Lond., of a son.

HEDLEY.—On the 23th ult., at Lawn-road, the wife of Brigade-Surgeon W. S. Hedley, M.D. (retired), of a son.

LITHGOW.—On the 2nd inst., the wife of T. G. Lithgow, F.R.C.S.Ed., L.R.C.P.Lond., of Stirling House, Farnborough, Hants, of a son.

MACLACHLAN.—On the 28th ult., at Fenwick, Thurlow-park-road, West Dulwich, the wife of Andrew Maclachlan, M.D., of a son.

ROBINS.—On the 4th inst., at Down Hall, Rippingale, Bourne, the wife of G. Norman Robins, L.R.C.P., M.R.C.S., of a daughter.

MARRIAGES.

BASS—BISHOP.—On the 29th ult., at St. John Baptist's, Crowthorne, Berks, Charles William Bass, M.R.C.S., of Langsett, Ilford, Essex, to Edith Mary, eldest daughter of George Bishop, of Wellington College, Berks.

BROWNE—GARRETT-SMITH.—On the 30th ult., at St. Mark's, Hamilton-terrace, James W. Browne, M.A., M.B., Fellow of Worcester College, Oxford, to Alice, younger daughter of J. W. Garrett-Smith, of Abercorn-place, N.W.

PAGE—GRACE.—On the 27th ult., at Downend, G. Shepley Page, L.R.C.P., L.R.C.S.E., to Katharine Fanny, second daughter of Henry Grace, of Kingswood-hill, Bristol.

SMALL—HALL.—On Aug. 17th, at St. Philip's Church, Sydney, N.S.W., John Small, L.R.C.S.Ed., L.R.C.P.Ed., of Geelong, Victoria, to Alice Maud, second daughter of the late Capt. R. Morgan Hall, of 48th and 13th Regiments, Bath, England.

WATSON—GREY.—On the 28th ult., at Newport, Isle of Wight, John Watson, M.D., of Royal Heath, Sandown, Isle of Wight, to the Lady Anna Tredger, youngest daughter of the late Rev. Harry Grey.

DEATHS.

ASHMEAD.—On the 4th inst., at Talbot House, Brierley-hill, Helen Wilhelmina Ashmead, the beloved wife of Geo. Ashmead, L.R.C.P.Ed., L.R.C.S.Ed., and youngest daughter of the late Captain Henry Walker, of Castle Stuart, Inverness-shire. Deeply regretted.

PEARCE.—On the 1st inst., at Eastbourne, George Pearce, M.D., of Leicester, aged 47.

SEATON.—On the 30th ult., at Halliford House, Sunbury-on-Thames, Joseph Seaton, M.D., F.R.C.P., F.R.G.S.

SHIRREFF.—On the 28th ult., at Sowdon Lodge, Lympston, South Devon, James Hales Shirreff, M.D., aged 73.

WATSON.—On the 28th ult., John Ferra Watson, J.P., M.R.C.S., of Helgham Hall, Norwich, aged 69.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, October 7th, 1886.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE ELECTION OF DIRECT REPRESENTATIVES.

AT the moment of going to press we have received advertisements with reference to the approaching election of Direct Representatives from the President of the Medical Council, who, for this purpose, is the returning officer. All nomination papers must be forwarded on or before Nov. 9th to the Registrars of the Branch Council of England, Scotland, and Ireland respectively.

G. We do not prescribe.

TONSILLITIS AND ITS RELATION TO SCARLATINA AND DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I am glad to find from Dr. Hingston Fox's letter that we are not so much at variance as at first sight appeared. That all cases of tonsillitis are not due to infection may, I think, be argued from the facts that some people are subject to constantly recurring attacks, and the severity of each is in no degree less severe than the preceding one. Then, too, there are some cases of tonsillitis accompanied with ulceration of the surface which, if treated with iron and quinine, go on from bad to worse, and yet rapidly improve under the effervescing citrate of potash. Now, were the ulceration due to septic poisoning, the very reverse of this would occur; and I therefore consider that the ulceration in these cases is dependent upon extreme distension of the surface of the gland tissue. Again, I may state that I and my family, though resident in different places, were at one time frequent sufferers from quinsy; and even now, were I to undergo excessive fatigue for a week or two and take my meals irregularly, I could easily bring on an attack. Never have I seen albuminuria or paralysis follow an uncomplicated case of quinsy, though one of the latter, it appears, was reported the other day by Dr. Prévost in the *Archives Médicales Belges*; and I have never known two cases to occur in the same house within three or four, and I think I may say with perfect correctness six, months of each other. In fact, I have never had a single case which could be said to arise from infection or contagion. I am, Sir, your obedient servant,

Surbiton, Sept. 30th, 1886. F. P. ATKINSON.

P.S.—It appears to me that Dr. C. Haig-Brown has somewhat mixed up simple inflammation of the tonsils with the follicular type of the disease; though, in my opinion, they are entirely different as regards their origin. The former is generally accompanied with enlargement and tenderness of the submaxillary gland or glands, the latter with enlargement and tenderness of the lymphatics.

A MONSTROSITY.

THE thirty-ninth number of the *Gazette Hebdomadaire des Sciences Médicales* contains two figures and descriptive text of a so-called cyclocephalic monster. The chief feature in the monster is the want of development of the nasal region, attended with the approachment of the two orbits, so that they have become partially fused. A further degree of this deformity leads to the complete fusion or want of differentiation between the two orbital regions, and there is then but one organ of vision. In the specimen in question there was a rudimentary nasal appendage which formed a kind of flap that partially concealed the abnormal orbital region.

A Twenty-five Years' Subscriber.—1. We consider our correspondent was not properly treated by the coroner if that gentleman made the remark attributed to him with the knowledge that our correspondent had been ordered to discontinue his attendance upon the deceased.—2. The remarks no doubt have a tendency to damage our correspondent's practice; but they are, of course, not actionable. Moreover, our correspondent's reputation is quite good enough to warrant him in treating the matter as beneath further notice.—3. We would not advise petitioning the Secretary of State.

Berkshire.—Probably next week.

"A CASE OF GUINEA-WORM."

To the Editor of THE LANCET.

SIR,—Your correspondent, "Reader," who seeks advice as to the treatment of a case of guinea-worm in your last issue, should take a piece of sticking-plaster about an inch and a half wide, and roll it tightly up to about the calibre of a No. 6 catheter, allowing the free edge of the plaster after cutting to the proper size to remain unrolled for the width of about half an inch. The protruding end of the worm (head end) having been first wiped dry by a dab from a sponge or carbolised cotton over it, and the sore whence it issues, and the little roll of plaster above referred to having been placed transversely beneath the worm and over the healthy skin beyond the point of exit, is placed across in regard to the long axis of the little spindle, and between the free surface of the rolled up piece of plaster, which are then closed over it and all firmly secured together. The little spindle is then taken hold of tightly at both ends by the thumb and forefinger of both hands, and most gently turned round underhanded, strictly on its own axis, so as not to drag, till a coil of the worm is wound around it, and is then secured *in situ* by means of a few narrow pieces of strapping. No attempt must be made to extract the worm at one sitting, or failure is sure to follow, and a gentle continuous traction and tension on the worm is only admissible, on which entirely will depend the successful issue. Should any spasmodic or undue strain be put on the worm it may break, as it is often rather friable, giving exit to acrid exudations and infiltration into neighbouring tissues, followed by severe local inflammation and irritation. As the worm often attains the length of some feet, and always several inches, I need not say that it will take some days, or weeks, to effectually get rid of it. The spindle need not be changed throughout the whole process; but it, and the little sore, must be kept well cleansed at each daily sitting with a weak solution of carbolic acid. It is quite obvious that the plaster spindle is much more pliable than ivory or any other solid material, and adapts itself to any irregularities of surface from which the worm often issues, and can be kept firmly *in situ*, without unrolling, by a little strapping, and without causing any undue strain on the worm. The watchwords must be *gentleness*, *patience*, and *time*. The patient, of course, must be kept quiet during the treatment.

I am, Sir, yours faithfully,

Truro, Oct. 5th, 1886. D. W. WILLIAMS, M.D.

W. E. (Belfast).—Perhaps the fullest and best treatise on cremation is that recently published by Professor Carlo Cucca of Naples. Of the various kinds of "ustrina," or "crematoria" (as they are less accurately called), he compares those of Polli, of Gorini, and of Siemens, and pronounces in favour of the last-named as not only the best, but the cheapest. He declares that cremation, instead of being optional (*facoltativo*) should be made obligatory in Italy.

Mr. Startin.—Yes, in an early number.

FEES FOR NECROPSY IN THE ISLE OF MAN.

To the Editor of THE LANCET.

SIR,—I notice in your issue of Saturday, Sept. 25th, a paragraph to this effect:—"The Governor of the Isle of Man, it is reported, has reduced the fee of £1 1*s.* for a post-mortem examination by order of the coroner to sixteen shillings." I am in a position to state that the report is incorrect. His Excellency has not reduced the fees, but rather increased them. Formerly the payment made for medical evidence before the coroner was 10*s.* 6*d.*, and the fee to which the medical man was entitled for a post-mortem examination and for the evidence arising therefrom, if such evidence were given, was £1 11*s.* 6*d.*; or in all, £2 2*s.* Now the payment is to be, for evidence before the coroner, 15*s.* 6*d.*, and for a post-mortem examination and evidence arising therefrom, £1 11*s.* 6*d.*; in all, £2 7*s.* I think it but right that these facts should be made public.

I am, Sir, yours faithfully,

Douglas, Isle of Man, Oct. 4th, 1886. J. A. DEARDEN.

A DEFENCE OF TEA.

AN article which appeared in our columns some weeks ago condemning the excessive use of tea as injurious has come under the observation of the Chinese at Shanghai; and a recent copy of the *Shén Pao*, a local native paper, contains a leading article which is evidently founded upon a misconception of the tenour of our remarks. The writer states that for several hundred years no one has heard that the habit of tea drinking is an injurious one. Why should it suddenly become so to-day? Moreover, tea has been drunk in China for thousands of years without any apparent ill-effects. Our contemporary then proceeds gravely to discuss the various sources from which this imagined danger may arise. The water cannot, it argues, be injurious, for it has been boiled; and as adulteration of the leaves has practically ceased, how can the pure article be injurious when the adulterated article which was exported and consumed for years had no evil effects? Another reason for the appearance of the article condemning tea has been suggested to the contributor to our contemporary; and although in his opinion it is not deserving of immediate and implicit belief, yet, looking at all sides of the question, he would not venture positively to state that it is devoid of truth. "It is said that a foreign doctor discovered a spring of water possessing valuable medicinal properties, and that after mixing some kind of preparation with it he put it up in bottles, like the lemonade and soda-water used by foreigners here; that as the demand was not very brisk, he originated this story about the injurious properties of tea, with a view of increasing the sale of his preparation." Despite, however, such a low estimate of the honour of foreign medical men, the writer concludes with the expression of high admiration for their professional skill, which he contrasts with that possessed by the native faculty much to the latter's disadvantage.

M.B. will have to obtain leave to practise in Spain. This may be granted to an English graduate without examination, but cannot be claimed as a right. We are making further inquiries, and will endeavour to answer our correspondent's query more fully in a subsequent issue.

Mr. Greenwood (Stronalyne).—There are several institutions of the kind, for a list of which we must refer our correspondent to the Charities Register, published by Longmans.

A NEW METHOD OF ARTIFICIAL RESPIRATION IN CHILDREN.

To the Editor of THE LANCET.

SIR,—For several years I have adopted a very simple method of performing the artificial respiration that is sometimes required in new-born infants, and as it is devoid of the display usually attending the present plan, which is sometimes so exciting to nervously constituted mothers, perhaps it will commend itself to many of your readers.

The child is laid in the supine position; the palm of each hand of the operator is placed on each side of the chest, with the nipples underneath the hands and the fingers overlapping the ribs and partly covering the abdomen. For inspiration the fingers are bent so as to catch under the free edge of the ribs, in order to raise the chest wall outwards and upwards, whilst for expiration the fingers are extended and pressed together with the palms of the hands on the chest and abdomen. Trusting this explanation is sufficiently lucid,

Believe me, Sir, yours faithfully,

Bournemouth, Oct. 1st, 1886. F. W. CORY.

Medicus (Sunnyland) will be obliged to pass the examination for the State diploma in order to practise in Switzerland. His best plan will be to write to the Dean of the Faculty of Medicine at Geneva.

Volo.—Our correspondent has a legal claim. Such claims have been allowed. Whether in any given case they will be recognised, or it is worth while to spend money and worry over them, is a matter for grave consideration.

A Beginner.—Roscoe and Grainger Stewart.

SOMETHING WRONG AT THE "COLINDERIES."

To the Editor of THE LANCET.

SIR,—I have just been made aware of a disgraceful state of things at the Exhibition at South Kensington. One of the *employées* informs me that since it was opened they have had to pay for the use of the waiting-rooms. Do you not think this is a very cruel arrangement? The poor girls are at their duties twelve hours each day. Some come from a distance, so that fourteen hours per day is about the average they are absent from home. They are charged a halfpenny each time they visit the room. To be healthy and comfortable 3*d.* per day is needed—1*s.* 6*d.* deducted from 12*s.* per week! Naturally, economy is practised. Consequently much misery is endured, and no doubt in many cases the foundation laid for painful diseases.—I am, Sir, obediently yours,

Sept. 30th, 1886. E. M.

SEVERAL articles and communications have been crowded out of our present number; amongst them being an editorial on the introductory lectures delivered at the opening of the several medical schools, annotations on various subjects, letters from numerous correspondents, &c.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Kidd, Dublin; Prof. Humphry, Cambridge; Mr. Weddell, Newcastle-on-Tyne; Dr. Williams, Truro; Dott. L. Vallardi, Naples; Dr. O. Sturges, London; Dr. H. R. Ker, Halesowen; Mr. R. Leigh, Liverpool; Dr. Porter, Sheffield; Sir Jas. Sawyer, Birmingham; Mr. Percy Dunn, London; Dr. Wadham, London; Mr. J. Black, London; Dr. A. Wilson, Edinburgh; Mr. M. G. Biggs, London; Mr. J. N. Tratman, Shanghai; Mr. H. Whates, London; Mr. A. G. P. Gipps; Mr. J. P. Hentsch, London; Mr. J. H. Pugh, London; Mr. A. D. Pithie, Greenock; Mr. Freeman, Pangbourne; Mr. A. J. H. Montague, London; Dr. Taaffe, Brighton; Mr. Kerr, Preston; Dr. Theodore Maxwell, Woolwich; Mr. Batterham, St. Leonards; Professor John Clay, Birmingham; Mr. Stretton, Kidderminster; Dr. J. F. Payne, London; Dr. Thurstan, Southborough; Mr. Fisher, Dundee; Mr. F. Treves, London; Mr. J. A. Dearden, Douglas; Messrs. Burroughs and Wellcome, London; Mr. F. P. Atkinson, Surbiton; Messrs. Brown and Son, Newcastle-on-Tyne; Mr. H. B. Hewetson, Leeds; Mr. F. W. Cory, Bournemouth; Mr. Hourigan, Freshford; Messrs. Wright and Co., Bristol; Dr. Lewers, London; Mr. Spurgin, Maryport; Mr. John King, Birmingham; Mr. Jas. Startin, London; Mr. A. E. Barker, London; Mr. T. Christy, London; Mr. Graham, Bristol; Mr. W. A. Dingle, London; Mr. Kenny, Buckhurst Hill; Mr. Phillips, Weston-super-Mare; Dr. Whitehead, Carlisle; Mr. Somerville, Edinburgh; Dr. Davies, Bridgend; Dr. Ward, Oxford; Mr. Manton; Messrs. Pratt and Co.; Mr. T. B. Browne, London; Mr. Wallace, Cardiff; Mr. Abbs, Dewsbury; Mr. Bingham, Grimsby; Dr. Whiteshap; Messrs. Lea and Co., Philadelphia; Dr. Braithwaite, Rickmar; Messrs. Kilner Bros., London; Mr. Garrard, Rotherham; Messrs. Boulton and Paul, Norwich; Mr. Groves, Dorchester; Mr. Rudkin; Messrs. Maw and Co., London; Dr. G. Harley, London; Messrs. Hopkinson and Co., Notts; Mr. Ewin, Leicester: Mr. Powell, Shifnal; Mr. Kershaw, London; Dr. Usher, Yeadon; Dr. King, Ilfracombe; Mr. Halliday, Bramley; Mr. Jones, St. Albans; Mr. Bigg, London; Mr. Rawlinson, Burnley; Miss Thomas, Liverpool; Mr. Elliot, Carlisle; Mr. Van Buren, London; Mr. George; Dr. Brailey, London; Dr. Radcliffe Crocker, London; A Beginner; W. L. M.; Tunbridgense, London; M.B.; Subscriber; Hopeful; Junius; Inquirer; B.M.; A Senior Student; A. B. C.; Vicar; M.D., Newcastle-on-Tyne; L. M. D.; One of Them; C. W., Brighton; M.D., London.

LETTERS, *each with enclosure*, are also acknowledged from—Dr. Heron, Glasgow; Dr. Williamson, Ventnor; Mr. Bowler, London; Mr. Gray, Bristol; Dr. Maclachlan, West Dulwich; Mr. Roberts; Messrs. Morgan and Scott; Mr. Chilcot, Ealing; Mr. Appleton, Beverley; Mr. Guest, Darlington; Miss Taylor, Clapham; Miss Jones, Derby; Mr. Green, Glamorgan; Mr. Hough, Derby; Dr. Morris, Spalding; Mr. Ellis, Bishop Auckland; Mr. Hoare, Bexhill-on-Sea; Dr. Aitken; Messrs. Lofts and Co., London; Dr. Wise, London; Mrs. Hitch; Messrs. Medical Diary for the ensuing Week.

Monday, October 11.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. Gordon Smith: Sanitary Appliances.

Tuesday, October 12.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, October 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M. Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. T. B. Rosseter: Trichodina as an Endoparasite; Desiccation of Rotifers; The Abbe-Zeiss New Objectives and Eyepieces.
HUNTERIAN SOCIETY.—8 P.M. Mr. Hutchinson: On the Value and Measuring of certain Symptoms.
PARKES MUSEUM OF HYGIENE.—8 P.M. Prof. F. De Chaumont: Ventilation, Measurement of Cubic Space, &c.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Dr. Meadows: Cæsarean Section.—Mr. Lawson Tait: Extra-peritoneal Cysts. Specimens will be shown by Dr. Edis, Dr. Fancourt Barnes, and others.

Thursday, October 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, October 15.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Dr. Alfred Hill (President): A Consideration of the Various Modes of House-refuse and Sewage Disposal.
PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. Percy Boulnois: Scavenging and Disposal of Refuse.

Saturday, October 15.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
To CHINA AND INDIA	One Year		1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES	Ditto		1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

ADVERTISING.

Books and Publications (seven lines and under)	£0 5 0
Official and General Announcements	0 5 0
Trade and Miscellaneous Advertisements	0 4 6
Every additional Line	0 0 6
Front Page	per Line 0 1 0
Quarter Page	1 10 0
Half a Page	2 15 0
An entire Page	5 5 0

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin Paris.

Introductory Address
ON
MYSTICISM, SCEPTICISM, AND MATERIALISM IN MEDICINE.

Delivered at St. Mary's Hospital, Oct. 1st, 1886,

BY MALCOLM MORRIS, F.R.C.S. ED.,
SURGEON TO THE SKIN DEPARTMENT.

GENTLEMEN,—The frequent and regular recurrence of events tends to produce indifference as to their nature and origin. As with the words of a language, so with the customs of a country—the original meaning is often lost in obscurity. Inaugural lectures form no exception to this result of time. So accustomed have we become to them, so gradual has been their development, so strong is their family likeness, that they are in some danger of becoming meaningless ceremonies. The introductory lecture is bequeathed to us by a bygone age. It comes to us as a curious academical heirloom, venerable with associations. In spite of a troubled past, it has retained much of its early peculiarity amid more than one revolution in the educational world. Little wonder that the initial purpose of this traditional form should have become obscure, and its original outline a little blurred.

It may, then, not be out of place to ask the purport of this now familiar ceremony? Its simple aim is to introduce the beginner to the study of medicine. In this sense it is clear such a lecture would be impossible at the present time. Its ambition would be beyond the scope of human capacity. One hour's discourse would hardly serve for the introduction of the student to a science that is one of the most complex and diffuse in the realm of learning. The ideal initiatory lecture was only possible at a time when that science was one of vague and narrow scope. In proportion as it has grown, the formulæ which once sufficed to introduce it have become dwarfed and inefficient. They have assumed the form of vehicles for advice, or have served to embody a few of the prevailing opinions of the time, or have been used to chronicle progress and to record experience, or to vaunt the all-importance of a particular school. Considered as the first of a series of technical dissertations they have ceased to exist. I feel, then, that I need not apologise for not attempting an impossible task; while, on the other hand, I must ask your indulgence for an effort that must needs be halting and imperfect. In the place of endeavouring to introduce the uninitiated to the entire science of medicine, I would venture to draw your attention this afternoon to certain historic phases of the modern art of healing that appear to me to demand consideration. A review of the aspects of medicine will serve, I hope, as an introduction rather to its environment than to its details. Instead of attempting a geological survey, so to speak, of the scientific planet itself, I will confine myself to an examination of the atmosphere in which it revolves. The first point to which I would direct your attention concerns the element of

MYSTICISM IN MEDICINE.

Could Lord Macaulay's New Zealander enter this assembly, he would be puzzled to recognise our business as that of the initiation of men into a knowledge of the processes of life and death. Medicine and mystery are with him interchangeable terms, and he would miss the incantation, the weird dance, and all the saturnalia that are for him the natural concomitants of the healing art. Noise, panic, and mystery are the three accessories of aboriginal medicine. The "medicine man" is a protoplasmic element in evolution—a primitive admixture of the charlatan, the fanatic, and the mountebank. He is, nevertheless, the germ from which, as a profession, we must acknowledge descent—our prototype in an age when science was but a slender figure arrayed in the too exuberant drapery of mysticism. Onward a century or so, we encounter this same germ developing into the physician of the middle ages—a gloomy compound of ignorance and superstition. He is still deeply mysterious, but there is in his art less of falsehood, more of truth, albeit he dabbles in spells and occult influences. He seeks to impress the common mind by means of mystic crucibles, and works hand-in-hand with the astrologer and the magician. But he is withal less of the quack, and more of the student of science. There is an earnestness in his unwearied search for the elixir of life, and some reality in his pursuit of the philosopher's stone. His room, exhaling the vapours of an unknown world, must have been a very den of terror. Yet to-day his grandest phenomena are eclipsed by the most unpretending conjuror. Still, this element of mystery was not wholly unproductive of good. It saved the life of science when threatened by a bitter fanaticism. Its spark was fanned by the love of greed when it had ceased to be maintained by the love of knowledge. At the risk of liberty and life the scientist toiled on in anxious seclusion, fearful himself and yet inspiring fear by reason of the exalted nature of the pretended objects of his researches. His was a position of great power, though the true spirit of scientific medicine was in the feebleness of infancy. Nearer to our own time is the period when with an increase of knowledge there came a decrease of mysticism. The supernatural was not quite abandoned, but a more tangible foundation for true learning was arising from the study of human anatomy. At this period was propounded the mystery of the humours of the body, the lymphatic, splenetic, and the like. The condition of the patient was said to be dependent on an admixture of these or the predominance of one of them, and it was the physician's work to endeavour to remove or to modify these humours. The belief in drugs was at its zenith; the examples of the old formulæ then employed that still survive are permanent evidences of human credulity.

Two questions naturally arise out of these considerations: First, How was the mystic element evolved? and, secondly, Has it entirely disappeared from the enlightened medicine of our own time? I think it will be found that the element of mysticism in medicine has been forced upon it by the public. It is the result of two opposing conditions—the absolute knowledge demanded by the laity on the one hand, and the more or less extensive ignorance of the professor of the healing art on the other. This ignorance, where it exists, he must not acknowledge. He is expected to be able to recognise disease and to know how to treat it. Yet no other professor is so "cribbed, cabined, and confined." The astronomer may admit want of knowledge. The chemist and the physicist may say, "*This* I know, *that* I do not know"; and the lawyer may, without loss of reputation, confess himself an agnostic in matters legal. But such an admission would be fatal from the lips of a medical man. With him nothing must be admitted that would disturb that most potent factor in therapeutics—absolute and implicit faith. Medicine, despite the strides it has made in modern times, is still extremely defective. This scanty lore must be supplemented by fiction. The public insists upon absolute knowledge. This cannot be obtained; it must therefore be invented. Had the public in the middle ages been content with the little learning the period afforded, the student would have been saved many volumes of nonsense, and the sick man a flood of obnoxious medicine. But they were insatiate, and would not be satisfied with a little. The phenomena of disease became associated with star influence, spirit agency and other dim powers. That in some directions this mysticism did much harm to science cannot be doubted, but happily its influence was not wholly paralysing. It gave at least a spurious dignity to the pursuit of knowledge at a time when the sum of human knowledge was by no means great. It offered attractions to aspiring men, whose imagination it stimulated; while it stifled in many ways the true spirit of scientific inquiry, it became a tempting lure to many in whose brains that spirit was quickening. It saved learning at a time when it was fast sinking into contempt, and it floated the little ark of science over a troubled and tempestuous sea.

And there is mysticism in the medicine of to-day. Athwart our paths may still be traced the track of the astrologer. There remains in the people a belief in the efficacy of drugs as drugs—a belief that as for every bane there must be an antidote, so for every disease there must be a curative leaf or root. Nature is distrusted; disease is still represented as some evil influence to be exorcised. In the popular mind disease walks the earth as a devouring fiend, and has a personality about it as of old. Our very phrases, "Stricken with disease," "Visitations," and "Seizures," are survivals of the conceptions of primitive times. There is still to-day a demand for

perfect knowledge from all professors of the healing art, and, as of old, the gaps in medical science—which is far from having reached the category of the exact—have to be filled with fiction, though less, it is true, in amount, and less unwholesome also in character. The mysticism survives in the courtly phrase and the ambiguous language of the practitioner of modern times. When sorely pressed by the sick man, the physician's only armoury is equivocation, from which he draws such verbal weapons as "the state of the constitution," "the tone of the body," "the general health," "lowered vitality," and *id genus omne*—a vicious circle of ambiguous platitudes, diluted to vagueness by the admixture of scientific terms. Are not these in some sort a survival of the circle of the horoscope? This antagonism between the public and professional mind is deplorable. It cripples investigation; it places the medical man in a false position, in which his dealings become artificial and his utterances evasive. At no far distant day, however, there is hope that medicine will have shed for ever the last vestige of mysticism, and what will rid it of such unworthy disguise will be the influence of a more carefully educated public. A great step in this direction is already being accomplished by the introduction of the elements of physiology and the laws of health as essential features in scholastic training. This knowledge is precisely what is wanted to qualify an individual to form a true estimate of the relations that should exist between the medical man and the patient. With a mind cleared of the crude absurdities in which his forefathers blindly confided, he will be of all men best able to appreciate the difficulties of the doctor and to be tolerant of his deficiencies. He will understand how to be satisfied with the known, without vainly clamouring for the unknowable.

SCEPTICISM IN MEDICINE.

Let me now invite your attention to what I may term the element of scepticism in medicine, an influence which will probably have no small share in moulding the medical man of the future. Intellectual development has been the most prominent feature of the present age. Both in extent and variety the attainments of science and of art have been prodigious. Examples are not far to seek. Down to the commencement of the present century the advance made in so simple a branch of practical mechanics as locomotion was altogether trifling. The revolution effected by the introduction of steam as a motive power was a revolution indeed! The adaptation of steam to this end gave an impetus to inventive genius that enabled it at one bound to outstrip the puny efforts of past ages of the world. The scientific step from the primitive chariot of ancient times to the stage-coach was wholly insignificant by the side of the great advance which will for ever be associated with the name of Stephenson. This result was not the work of centuries. The whole of the vast revolution was conceived and perfected in the lifetime of an individual man. In the art of lighting, the process of development was hardly less startling and sudden. All that the knowledge of ages had done in that direction was but a trifle in comparison to the introduction of gas. Here, too, the entire change has been effected within the limits of one generation; indeed, within the recollection of, I daresay, more than one here present to-day. And what a host of other marvels does this period include. Picture the world before the introduction of the telegraph. We can hardly realise the fact that there has been a period within the memory of living man when yet it was not. Its coming united humanity into one family. It was the one touch of science that made the whole world kin. Electric force is to-day one of the main bonds of our civilisation. It is difficult to imagine that these advances in science have been made since this century opened. In every direction we see indications of the same marvellous activity of thought. We see the various departments of science combining for mutual benefit, working harmoniously, and producing unexpected results. And even more stupendous have been the movements in the philosophical world. It is not too much to assert that the Darwinian theory invested our very existence with a new meaning. It was a revelation that startled the whole civilised world. It shed a light on the science of life that necessitated the re-writing of its history, destroying at a blow many previous systems of thought. Something of a like revolution took place in mental philosophy, in the study of the human intellect, and the analysis of the human emotions, on the introduction of the anatomical element. Before this our conception of mental movement was shadowy [illegible] unsubstantial. Anatomy lifted many obscure questions into the light of day. It has already given us the key to many mysteries of the mind, laid bare many secrets of the senses, and has provided a basis for the solution of matters that are still impenetrable.

Our age is one of tumultuous mental activity. Old forms of belief are on all sides being assailed; primeval faiths are crumbling to decay. The philosophy of the past is either dead or dying. Old things are passing away; a host of ancient prejudices are tottering to their fall; and such is the rapidity with which we are moving, that scarcely have they been levelled with the dust when new creeds spring vigorously from their ruins. Such are the times in which we live, and they are times in the highest degree favourable to scepticism. It is rampant among us at this moment. Speculation is rife, and it is a blemish which medicine has not escaped. Scepticism has infected medicine fully as much as it has religion. Where to-day is the implicit belief in drugs which was a dogma of the healing art in past times? Like many another faith venerable and unquestioned by our forefathers, it is losing or has lost its hold upon men's minds. The extreme sceptic boldly avows his entire disbelief in the potency of any drug whatever; others less dogmatic content themselves with acknowledging the value of a drug or two. The position is attained where scepticism, wrapped in its own self-confidence, once and for all repudiates all aids and accessories; briefly, it states its deliberate opinion that disease is infinitely better left to itself. The natural physiological energy of the body is the prime element in the healing process. This is neither more nor less than modern fatalism—waiting on events. Such a doctrine, if successful, would be fatal to medicine. Without doubt the element of interference has been far too prominent in the past. But there are absolutely no just grounds for rushing to the opposite extreme and forswearing the use of remedies merely because they have once been administered in gross excess. The remedy is as bad as the disease.

There is no use in blinking the fact: young men are and always will be naturally attracted by scepticism. There is about it a sensational fascination congenial to the developing and active mind. It is a bias, however, most vigorously to be withstood. Scepticism as such is too often adopted as the alternative to careful reasoning and the patient examination of facts. In training the intellect, the student will find it advantageous to cultivate that form of it which is the chief characteristic of the judicial mind. A judge's duty is twofold. It is not sufficient that he shall be able to arrive at a just decision upon the facts *presented* for his consideration; he has, in the first instance, also to decide what facts are admissible as evidence. On these and on these alone must his final judgment be based. The rules of evidence are known to every advocate, but, having the whole case to handle, he cannot devote so much attention to the question of the acceptance or rejection of this or that evidence as can the judge who is less hampered with details. Like the judge, we have not only to sift that which is given us, but to watch and to seek out whence it comes, and to look to it lest any who may have pet theories to support may find us so-called facts to fit them. Special pleaders are by no means monopolised by the bar.

Changes of belief irresistibly forced upon a man by the accumulation of facts and the weight of well-stored experience are worthy of all respect and consideration. But many forms of scepticism in modern medicine are rather to be deemed emotional and infective, and as such are apt to take possession of the learner, who will be tempted to accept his creed upon judgments other than his own. Whatever we profess, whatever we deny, let us see to it that we are able to give "a reason for the faith that is in us," and that reason is at least our very own.

So much for the elements of mysticism and scepticism. Let me now ask your patience a few moments while I refer to the third aspect of my subject.

MATERIALISM IN MEDICINE.

Materialism must be viewed as a useful and indispensable feature in the study of medicine. It was the absence of this element as a firm basis and starting-point that was mainly productive of the mischievous results we have considered under the head of mysticism. We have seen how medical science suffered at the hands of the alchemist and astrologer: can we be quite sure that it is in no like danger from the well-intentioned but too restricted efforts of the materialist? The mind requires a field neither too large nor too small. Formerly, the tiny light of science wasted all its

rays in the vain attempt to illumine regions far beyond its ken. The result was mysticism. To-day materialism threatens to err almost as much in the opposite direction by throwing all the little light it can command upon a pin's point. The man of science in the middle ages lifted his rushlight to the skies, and, soaring, lost its glimmering aid. In our own time he stoops so low as practically to hide its light beneath a bushel. While we are minutely inspecting matter as matter, we are narrowing our vision, and shutting out the broad issues which must be read with it, if we would rightly comprehend those enigmas of life to which matter affords the only key. While we minutely analyse the details, our eyes are out of focus for the broad truths the sum of them should teach us. Medicine should attempt not only to acquire facts, to accurately record phenomena, to compare kindred appearances: but it must go a step further and strive to grasp their wider significance, their general bearing. Many questions have been practically shelved, because men have become absorbed in the process of grubbing over a few minute details. The mind has been led away from a right conception of the whole by a too minute consideration of the part. In saying this, I would not be understood to disparage the practice of fact accumulation. It is of incalculable value as a means to an end. All honour to those whose lives have been devoted to a work so arduous, so unattractive. But in modern medicine we are apt to make too much of a fact *per se*. Let us have a care that in moulding the medicine of the future the constructive power claims its due and proper share of our consideration. At present the process is one rather of disintegration. Disease is being studied almost exclusively in regard to its minutest issues. We happen at this moment to be greatly concerned in the microscopic investigation of disease, having traced its source, as is confidently asserted, to bacteria. The inquiry, which is undoubtedly a most valuable one, is absorbing the genius of the time. Time was when that fatal scourge, consumption, was attributed to certain humours in the blood. Further investigation led to the conclusion that it owed its origin to a small particle—the tubercle. And now, in our own time, scientific inquirers have pushed their inquiries to such an extent that the most minute living particle known is reputed to be the parent of this fell disease. There is something uncanny in the contemplation of this minute organism. It may be almost taken to represent the limit of philosophical inquiry. But wonderful as the discovery is, do we know any more concerning the disease itself? Do we save more lives than did our forefathers? This is the crucial question which should be the touchstone whereby to measure our success. In the examination of disease, it must not be supposed that all truth lies at the bottom of the microscope, any more than at the bottom of the proverbial well. While men were worshipping facts as facts, Darwin was busy constructing his great theory. Facts were the basis upon which he built his grand superstructure; but no amount of unreflective pursuit of mere detail, however persistent, would have given the world the Darwinian theory. I say, then, and I would urge it strongly, that pure materialism in medicine may be carried to an injurious extreme. In modern pathology, for example, as originated by the German school and taught by its apostles, while men are actively contesting as to the nature or formation of a certain cell—whether it be spindle-shaped, round, or ovoid; whether it be derived from this tissue or from that—they are likely to lose sight of the real bearings of the case. By all means respect facts, and you cannot better show respect for them than by using them. A medical inquirer is not a mere collector. Collect your facts, and then reason from the data you have established. A collection teaches nothing till it has been arranged. The tendency at present is, in the majority of instances, to collect everything and to arrange, and therefore to adduce nothing.

One last word—and I speak now as a student to students. I have done my best, in an imperfect way, to point out what I conceive to be some of the dangers that surround the study of medicine. I would warn you to avoid the mystic on the one hand, and the sceptic and materialist on the other. But while I have been suggesting what not to do, you must understand that progress cannot result from negations. There is one condition upon which your success will in the main depend. Without this your efforts must be abortive. I refer to the oft-quoted but little-heeded precept—"Work for work's sake." The days of *walking* the hospital are over; it is now *working in* the hospital. You have a hospital and school wherein to work of which you may justly be proud. And you have in our Dean an example of energy and perseverance which you may well imitate. It is to Mr. Field that we are chiefly indebted for our present position among the metropolitan schools. You are entering a serious and earnest profession. Medicine is a goddess that brooks no divided worship. She will have all your faculties or none. She demands an actual sacrifice—a complete devotion to duty without adequate reward. This is the true diploma of medicine, and without it we cannot consider ourselves to be qualified. Medicine is noble just so far as it is unselfish. Clearly understand that you are entering upon a career in which work is inadequately paid, honours are few, and the struggle for existence keen and constant. But, in spite of this, there is something in the contact with disease that stimulates even the most prosaic, and that something is best told in words uttered forty years ago on a similar occasion to the present by Sir James (then Mr.) Paget. "There is not," said he, "in this world a nobler spectacle than that of a rational being devoting himself with patient, earnest perseverance to the cultivation of his powers, that they may be employed in the discharge of duty. Knowing that a force within him is capable of unlimited expansion, and confessing in his inmost consciousness that its development and its exercise are duties of strongest obligation, he pauses not to ask whether outward reward will crown his work or not; much less, with scrupulous calculation, does he count the cost and gain. But, because he knows that the powers and opportunities he has received were given him for use, he resolves that not one of them shall run waste or wild: for him to be indolent were to be unthankful. And so, in toil, yet not in weariness, he pursues his way; sowing seed, of which he reckons not whether he shall reap the fruit; content, because he is in the path of duty; blest, if only he may see or think that he ministers to the welfare of his fellow-men." It is to this toil that we bid you welcome to-day.

There is on all sides a constant cry for rest. Let not this cry be heard during your few years of study. Remember well the solemn words of Arnauld—"Rest? rest? Shall I not have all Eternity to rest in?" The life you must look forward to is one that can only stimulate the imagination of the strong man. A vast multitude of the practitioners of medicine die in harness. They die as they have lived. They never attain to that oasis of rest to which their long labours give them so earnest a claim. They are debarred the very peace they have been instrumental in bestowing upon others. And in many and many an instance they only find the long-sought-for rest when that time is reached of which Browning speaks—a time

> "When something like a white wave of the sea
> Breaks o'er the brain and buries us in sleep."

THE CONNEXION BETWEEN PULMONARY PHTHISIS AND OVARIAN DISEASE.

By BEDFORD FENWICK, M.D., M.R.C.P.,

ASSISTANT-PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, AND TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE.

IN one of the most recent works upon the subject, the author[1] writes: "Of the causes of ovarian tumours nothing positive is known." But various observers have each adopted a pet theory to account for the production of these new growths. For example, Dr. Safford Lee[2] firmly believed that parturition created a tendency thereto. All the facts and figures, however, on which he based his belief would apply much more forcibly to prove that pregnancy was the active agency at work. While, on the other hand, it is most difficult to see how the mere emptying of the gravid uterus—an intrinsically natural process—could excite the slowly developing degenerative changes which more recent pathology has taught us takes place in these cases. Then Scanzoni taught that chlorosis, with its consequent amenorrhœa, was the great cause. But it is evident that this alone cannot possibly be the case, or the factory hands of London and our manufacturing centres would swell the numbers up to tens of thousands. Whereas, Sir Spencer Wells, in his classical work,[3] writes: "Calculations, based

[1] Peaslee on Ovarian Tumours, p. 86. [2] Ibid., p. 88.
[3] On Ovarian and Uterine Tumours, 1882, p. 244.

upon the Registrar-General's report, make it appear that the female population of England and Wales comprises an average of 11,000 cases of ovarian disease, with an estimated duration of life of four years each." And the above argument of the comparative infrequency of these growths would equally apply against another theory, that profuse menstruation and its consequent anæmia is the *fons et origo mali*. One more theorist condemns marriage, and yet another the state of single blessedness. But statistics show very little in support of either view. Of Sir Spencer Wells's 1000 cases, 569 were married and 431 were single—a fact which, considering the normal numbers in each condition, does not exhibit any marked preference on the part of the disease. Finally comes the question of pregnancy or sterility. Dr. Peaslee gives his whole and valuable support to the latter theory. Believing that the ovary needs rest as much as any other organ, he says that it is never at peace except during gestation and lactation, and that the ovaries, therefore, of a woman who has borne even one child have had probably eighteen months' rest out of thirty years' hard labour, while the organs of a childless case have never ceased from work. So he sums up the matter thus:[4] "It is the non-gratification of the instinct for procreation, and not the disappointment of mere sexual desire or of affection, which determines the result apparently in these cases." But the whole of his argument seems built upon the other theory: that the ovary, to keep healthy, must needs have rest from work. For my own part, I must confess that I fail to see that this necessity is proved. The lungs do not cease to fill and to empty, or the heart to contract and expand, till life itself is ended. We do not expect, or altogether desire, them to take a moment's rest. Why, then, should the ovary require eighteen months'? Bearing in mind the intimate, nervous, and vascular connexions between the ovary, the uterus, and the breast, it is at least easily to be understood why an increased hyperæmia and functional activity of either or both of the latter two organs should involve a comparative anæmia and inertia of the first-named. But even then we must always remember that it is by no means absolutely certain that during gestation and lactation the ovary necessarily obtains functional rest. Indeed, many well-known clinical and pathological facts would rather tend to prove that it does not do so. When, however, we look at the facts and figures of the theory—none of which, by the way, are furnished at first hand by Dr. Peaslee himself—we find the argument weaker still. "M. Boinnet states that out of 500 cases *collected by himself* (the italics are mine) he found that 390 had never borne children"—that is to say, only about one woman in five in this unique series had been pregnant. Far be it for me to question the authenticity of these figures. I would only note that, as I have said, the series is unique. Then "M. Carlier has made the observation that cows which do not calve have ovarian cysts." The utter vagueness of this generalisation is rather bewildering. But it may be pointed out that, whatever may happen to cows, human females have been known to conceive and bring forth children while known to be suffering from cystic disease of one or both ovaries, and that most families have at least one member who has never conceived and yet has not been attacked by the disease in question. Now these apparently are all the facts, all the figures, all the arguments which have been brought forward to prove the theory that sterility is an exciting cause of ovarian cystoma, or, if I may so put it, that a passive negative state can excite an active positive degeneration. But, on the other hand, out of the 150 cases upon which this paper is based eighty had borne one or more children, seven had had one or more premature confinements, and only sixty-three of the whole number had never conceived at all. And, as I shall shortly show, these form a series of perfectly typical and unselected cases, so that in all probability they will represent the ordinary proportions of childbearing and childless cases of the disease. And, finally, if sterility by itself played any part in the production of ovarian cystoma, it is evident that the disease would be much more common than it already is in England, and, secondly, that it would be much more common still in other countries where the marriage-rate is lower and the birth-rate greatly less than in these islands. For example, the most recent statistics show that the population of Great Britain is doubling itself every sixty years, that of Germany and Austria together in every 110 years, and that of France in 140 years. But the rough figures which are obtainable on the subject from other countries would seem to show that ovarian disease is even less frequent abroad than at home. So that, however fallacious these figures may be, at least we may conclude that it is not a more usual affection among other European nations than our own. Consequently, I am led strongly to believe that sterility by itself has but little or no influence in the causation of cystic diseases of the ovary. It only remains, therefore, to consider the question of the influence of gestation; and, in the first place, I would recall attention to the normal physiological process which takes place in the Graafian follicle when impregnation of the lately-contained ovum has taken place. We know that, instead of the clot being absorbed and the follicle obliterated in a month, the process is so gradual that it is prolonged through the nine months of pregnancy, and even perhaps for a month or two afterwards. Is it not evident, therefore, how much greater is the possibility of the degeneration and liquefaction of the follicular contents during this greatly prolonged process of absorption than during the active obliteration of the sac begun and ended in one intermenstrual period? Pathologically, therefore, the probabilities are in favour of the theory that gestation may be an exciting cause of ovarian disease.

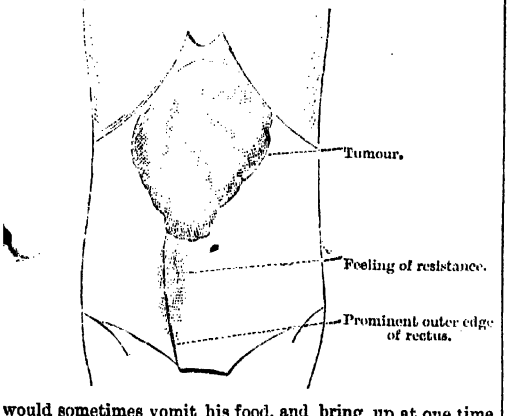
I deeply regret that Sir Spencer Wells does not afford us, in his work on the subject, the clear light which he throws upon any question which he has investigated. For I believe I am correct in saying that he has not given any authoritative decision upon the point of the causation of this disease. But out of the 150 cases which I have referred to, 87, as I said before, had been once or more pregnant, and only 27 of the remaining married cases had never been so at all. These figures, I frankly admit, are too limited to prove much; still, I think they tend to show that gestation may be a factor in the production of the disease. Then I would lay some stress upon the fact that so many patients date their illness from their last or some previous labour—a fact which so strongly impressed Dr. Churchill that he endeavoured to found upon it the theory that pregnancy was an exciting cause of the cystic growth. But it is only when labour has emptied the uterus that the patient notices the swelling of the abdomen, and the discomfort or pain produced by the tumour itself. And all who have had anything to do with these cases will recall how frequently a patient says that her first intimation of her complaint was that after a confinement her abdomen did not regain its natural contour, but remained more or less large and distended. In no fewer than eleven cases out of my series of 150 this fact had so impressed the patient that she succeeded, I find, in so impressing the clinical assistant that he made a special note of it. Of course I do not regard this question as settled by any means. We must have a great many more, and a great many more accurate, facts before the theory can be regarded as definitely proved. Still, I venture to believe that I have shown good and sufficient cause for drawing attention to its probability at least, and to the need for further investigation of the question. For if it be proved beyond cavil or doubt that gestation is an exciting cause of ovarian cystoma, the practical lesson as to prevention is plain, and important beyond measure.

There is yet another possible exciting cause which I have not seen specially noted, but which I am inclined to think is, perchance, more frequently the *fons et origo mali* than we at all suspect. I mean some accident giving rise to sudden hyperæmia of the ovary, and perhaps, through the consequent disturbance of its rhythm, to the commencement of the cystic degenerative change. Every clinical observer knows how often a fall or a strain is followed by ovarian pain or by hæmorrhage from the uterus, and how very often cases of ovarian prolapse or of chronic or subacute ovaritis are referred by the patient to some such accident when we investigate the history. And of the present series I find three well-marked cases in which the woman attributed her illness to a like cause. One, a married woman, aged forty-one, enjoyed good health till she was thrown from a cart. Great pain and swelling of the abdomen followed, and the latter slowly and steadily increased for five years when she came under treatment, and had a large ovarian cyst removed. Another, a single woman, aged twenty-four, fell downstairs and at once experienced great pain in the side, followed shortly afterwards by swelling, which gradually increased for eighteen months, when she was operated on for ovariotomy. I have heard of other cases where tumbling off a ladder or lifting a heavy weight was followed at once by abdominal pain and the formation gradually of an ovarian cyst, so that I must

[4] Op. cit., p. 89.

[4] Op. cit., p. 89.

strongly express my belief that falls or severe strains may form an exciting cause of the disease. And now, briefly to review our progress so far, I have shown grounds for belief that gestation and accident may be potent exciting causes of cystic disease of the ovary, and that other theories which have been advanced do not bear rigid investigation.



(To be concluded.)

SOME REMARKS ON THE OPERATIVE TREATMENT OF CHRONIC OBSTRUCTION OF THE SMALL INTESTINE.

By R. L. KNAGGS, M.A., B.C. CANTAB., F.R.C.S. ENG.

(Concluded from page 668.)

CASE I.—F. M——, aged fifteen, was one of a family of eight, six of whom died young. He himself had had scarlet fever, measles, whooping-cough, and croup; but on April 15th, 1885, was quite well. On that day he stayed in a swimming bath two hours. The same night he was seized with shivering, and the next day had severe pain in the abdomen, which was so tender that he cringed at the slightest touch. On April 23rd he was admitted into the Fever Hospital for typhoid (?). The main features of his illness were at that time as follows:—(1) The pyrexia never high, the highest point being 102·6° lasted three weeks from admission; (2) the abdomen was distended; (3) there were no spots; (4) the bowels were never moved, except by enemata, until solid food was given, when they were opened naturally; (5) the child remained so thin when convalescing as to give rise to a suspicion of tubercle, but of this there seemed to be no very definite evidence. The boy left the Fever Hospital on July 4th, and a fortnight later began to have attacks of abdominal pain about the umbilicus, which "bent him double." In another fortnight vomiting set in, and he

would sometimes vomit his food, and bring up at one time "all that he had taken" for several days. Then a tumour, accompanied with pain and nausea, appeared at intervals in the upper part of the abdomen. Formed motions were passed daily till a week before admission to the infirmary, when they became fluid. Three months previously a little blood had been found in his motions. He had had a solid diet, and had lost a stone in weight during the previous six months.

On Jan. 29th, 1886, the boy was admitted into the Huddersfield Infirmary under my father's care. He was very emaciated and had a hectic flush. There was a distinct fulness both to the touch and the eye in the umbilical, epigastric, and both hypochondriac regions. The iliac regions were hollowed out, the spines being very prominent. The abdomen was resonant all over. After short palpation a prominent tumour appeared in the upper part of the abdomen, and active peristalsis of the distended intestines was plainly seen. This was accompanied by considerable pain, nausea, and gurgling. The shape of the abdomen was quite altered by the tumour, which stood out to the extent of two or three inches and disappeared after lasting a minute; it occupied the position shown in the above diagram. Under chloroform a feeling of resistance that had been noticed running from the inferior limits of the tumour towards Poupart's ligament resolved itself into the sharp outer edge of the right rectus, beneath which was something that felt like a length or coil of intestine containing some doughy material. The rectum was quite empty, but considerable resistance was felt upwards and to the right. Specific gravity of urine 1020; no albumen. The following treatment was adopted:—A quarter of a grain of extract of belladonna, in form of pill, three times a day, belladonna ointment applied to the abdomen, and a diet of peptonised milk only.

Fluid motions continuing to pass, and the boy's condition remaining unaltered, it was decided, after consultation, to explore the abdomen. The diagnosis was chronic obstruction from matting of the small intestine, and the exploration was undertaken in the hope of removing the obstruction either by separation of adhesions or by enterectomy. On Feb. 17th Mr. Knaggs accordingly performed the following operation. A median incision, five inches long, was made, extending from an inch above the umbilicus. No layer with the usual characters of peritoneum was met with. A few adhesions between the parietes and the bowels were separated, and at the bottom of the wound were exposed loops of collapsed small intestine, closely agglutinated by adhesions, and containing a few scattered lumps of fæces. This collapsed intestine was thought to constitute part of the obstruction, and it was traced in one direction, its adhesion to the parietes and other portions of intestine being separated while doing so. Tracing some six or eight inches to the right showed the bowel to enter some structure at right angles probably the cæcum—and so the tracing was reversed. After about another foot of intestine had been unravelled the finger was able to explore in the direction of the tumour, and felt what was probably distended intestine. Now, as the tracing went on, one or two knuckles of bowel were exposed, whose covering bore some resemblance to normal peritoneum, but still considerably altered by adhesions. It was evident that the portion of the bowel above the main obstruction was being approached, as these knuckles were full of fluid, though not greatly distended. But adhesions seemed universal, and the finger could not enter any definite cavity where the intestines were free from adhesions. A part of the bowel had now been reached which did not seem to have been much obstructed, and the intestine below it was beginning slowly to fill. The operator now began to divide the organised bands of lymph, which considerably contracted and distorted the collapsed coils. When this was done the coils were found to be decidedly fuller. The filling having taken place almost imperceptibly, and the operation having been very tedious and prolonged, it was deemed advisable, in the absence of any very clear indication, to bring it to a conclusion. The coils of intestine were returned into the abdominal cavity, a Keith's drainage-tube was placed in the recto-vesical pouch, and the incision closed. The dressings were so arranged that the tube could be emptied without interfering with the wound. The tube was nearly filled with boracic lotion and enclosed in other antiseptic dressings.

The patient was kept under the influence of morphia, given subcutaneously, and fed by nutrient suppositories and enemata. The temperature, which before the operation had run a normal course, was 102° on the night of the operation, but afterwards fell as low as 99°. The pulse varied from 120 to 140. The tube was dressed night and morning. At the first and every subsequent dressing a considerable quantity of purulent-looking discharge, having a decidedly fæcal odour, was taken away, the tube being on each occasion filled with boracic acid solution till it was perfectly clear. On Feb. 19th the material was a coagulated mass of lymph. On the 20th he had a copious motion, portions being formed; and during the night he was delirious and restless. On the 22nd, after another similar night, the bowels were again well opened, the motion being partly solid and partly fluid. The patient had become very exhausted, and died about 10.30 A.M., half an hour after the tube had been dressed.

The necropsy was made by Dr. L. P. Bevan, the abdomen only being examined. The incision was found to be imperfectly healed, and where unhealed it was unhealthy-looking. Fæcal matter filled the channel of the drainage-tube. On opening the wound the exposed coils were seen to be covered with greenish lymph, which was only superficial. The unravelled [redacted] formed fresh adhesions,

but they were distended, as was also the large intestine. By taking a point two inches above the umbilicus, and drawing imaginary lines from it to the lower ends of the costal arch, a diamond-shaped space was formed. Below this space the peritoneal cavity was practically obliterated; in the space itself there were numerous adhesions and bands, many of them of great strength, but the intestines here still maintained some peritoneal lustre, and were somewhat freely movable; they were dilated and thickened. Scattered throughout the abdominal cavity were a number of light-coloured caseating masses, some of a semi-pultaceous appearance, others more solid, and shining through a layer of peritoneum or false membrane. Several were found in the mesentery, others apparently in the midst of adhesions. One was placed in the anterior wall of the bladder, and another close to the pylorus on the greater curvature of the stomach. One of these masses, in the right lumbar region, had partly broken down into pus. The intestines were soft, and more than once gave way as the adhesions were being separated. The mucous surface of the intestine showed a small circular ulcer, with raised thickened edges, at the upper part of the ileum; and in the large intestine, close to the cæcum, was a group of some five or six perforations, with rounded edges, of varying size, the largest being almost as big as a shilling; one or two had a well-marked fenestrated appearance. Externally there were the remains of adhesions. The rest of the large intestine was healthy, except for the lymph external to it.

CASE 2. E. R——, aged forty-three, married, no children. She dated her illness from March 7th, 1885, when she was seized with pain in the abdomen, and the bowels, which had hitherto acted with great regularity, ceased to act well. For ten days she felt poorly, with anorexia and abdominal pain, but no tenderness, and the bowels continued to act in an insufficient and irregular manner. Then she began to vomit, and the state of the bowels got worse and worse, in spite of aperients. She vomited daily, sometimes three or four times, and would bring up at intervals as much as a couple of pints of greenish fluid, after which she was considerably relieved. When seen by my father on May 7th, he found her much emaciated and exhausted, and unable to retain anything on the stomach. A hard swelling was perceptible towards the left side of the abdomen, extending from near the umbilicus to the pelvis. There was also retroversion of the uterus, but this seemed to have no connexion with the malady. She was placed upon liquid peptonised food, and a quarter of a grain of extract of belladonna, in form of pill, was ordered to be taken three times a day, belladonna ointment being applied to the abdomen.

On May 11th, 1885, she was admitted into the Huddersfield Infirmary, and the same plan was continued. No satisfactory progress was made. The bowels were never opened, except by enemata, and then only a few small scybala were passed. The vomiting continued as frequent and as copious as before admission, and the weakness and emaciation increased. An exploratory operation was therefore decided upon, and on June 20th, after consultation, Mr. Knaggs opened the abdomen in the median line by an incision three inches long below the umbilicus. Cautious exploration was then made with the finger, and a growth, or succession of growths, solid, and of a yellowish-white appearance, was felt and seen, evidently embedded in the mesentery, and extending downwards from about the position of the upper part of the left kidney to the left side of the pelvis. The peritoneum was studded with an infinite number of small tubercles.

The case seemed so hopeless that nothing further was attempted. The wound was closed, and it healed by first intention. There was no interruption to recovery. The results of the operation were singular and most unexpected. The patient vomited once within the next twenty-four hours, and for the last time. The bowels in a few days began to act with regularity, and improvement has been steady though slow. The patient when I last saw her (April 30th, 1886) was in a fair state of health, and able to get up and do light things about the house. She was better than she had been at any time since she left the infirmary, and she was continuing slowly to gain flesh both in the face and body. She every now and then suffered considerable pain from flatulence, and very frequently loud gurgling could be heard all over the room. She had only vomited two or three times since leaving the infirmary, and then the vomit was small, and due to something that had disagreed with her. The bowels acted twice daily, and the belladonna had been discontinued. No sign of disease existed about the lungs. When the intestines were not distended with gas there was a resonant tumour of variable size, reaching from the umbilicus to the pubes, and evidently a mass of matted intestines. There was a movable lump as big as a walnut in the left iliac fossa, which had not varied in size, and was probably a large gland or a tubercular mass. At the fundus of the uterus was a craggy mass, which was close to a puckering and thickening of the mucous membrane of the rectum—probably healed ulceration.

Dr. Fagge in his article on intestinal obstruction,[1] after noticing that the primary cause of "contractions" was generally a chronic peritonitis, adds: "It might therefore be thought that ordinary strumous peritonitis would be likely to give rise to similar effects. Such an occurrence must however be rare, for I have looked up all the fatal cases in our modern post-mortem records without having met with any one in which symptoms of obstruction are stated to have existed." He then narrates a case, to which there was no history, to show that strumous peritonitis may cause narrowing of the intestine to such a degree as to lead to dilatation and thickening of the bowel above the narrowed part. Dr. Fagge has since recorded a case in which the obstruction was due to this cause.[2] And Mr. Maunder[3] records a case of "intestinal occlusion dependent upon tubercular disease of the intestines," where the tubercular deposit was entirely "in the substance of the peritoneal covering."

The two cases here recorded, which occurred in the practice of one surgeon within eight months of one another, were brought almost to death's door from the results of intestinal obstruction, and in neither was tubercular peritonitis suspected as the cause until the operation showed it to be so in the one and the post-mortem examination in the other. That tubercular peritonitis does not necessarily contra-indicate or add very seriously to the risks of an operation is sufficiently proved by the result of the second case. There is hardly room for doubt that the operation has already prolonged the patient's life many months, and her continued improvement in health without regular medicinal treatment may fairly raise the thought that the incision itself may have exercised a salutary effect upon the course of the disease. This case may be considered in connexion with Sir Spencer Wells' classical case in which recovery seemed to date from a sharp attack of peritonitis that came on after the incision. Another remarkable case has recently been recorded by Mr. Lawson Tait.[4]

In the first case no operation would have been attempted had the real state of affairs been foreseen, but appearances were thought to point to a localised lesion, and the circumstantial history of typhoid, doubtful as it may now appear when critically examined by the light of subsequent events, tended to obscure the diagnosis. I have very little doubt that what was looked upon as typhoid was really a subacute commencement of peritonitis or an exacerbation of one previously existing; yet it was quite within the bounds of possibility—perhaps even of probability—that the typhoid condition should have originated a localised peritonitis, and the feeling of resistance leading to the right groin was in favour of that suggestion; whilst the perforations that were actually found so close to where typhoid perforations might be expected is of interest when we consider the history of the case. The group of perforations at the beginning of the large intestine is interesting. Perforation of a tubercular ulcer is a rare but still an occasional occurrence, and an interesting case is recorded by Dr. Hale White.[5] The present case is remarkable from the fact that a group of ulcers perforated. Before the perforations occurred the intestines must have been glued together, and a fatal peritonitis prevented. How far they may have owed their origin to the dragging of an adherent coil upon their floors, already softened by the results of inflammation, it is impossible to say, but this does not seem an unreasonable explanation. It is curious that during the operation so little should have been seen of the remarkable conditions that were really present. Except one or two suspicious circumstances, which investigation failed to clear up, no inkling of the true cause was gathered. The collapsed coils exposed by the incision were not inconsistent with a

localised matting; but it was not till after death that by continued unravelling the true state of affairs became apparent.

In the second case, it is difficult to understand what led to the removal of the obstruction. It is possible, but unlikely, that some accidental touch during the operation may have done all that was necessary; but I incline rather to the belief that the relief was afforded in the same way as it is sometimes by an enterotomy. I think that the very careful feeding after the operation, assisted possibly by the vomiting, so reduced the distension above the obstruction and prevented its reaccumulation that the natural passage was restored, and that the action of the belladonna, with the subsequent careful diet, were sufficient to keep it open.

Huddersfield.

WHAT CONSTITUTES MALIGNANCY?[1]

By HERBERT SNOW, M.D. LOND.,
SURGEON TO THE CANCER HOSPITAL.

THOUGH we are by no means yet in a position to solve the great mystery which surrounds this question, it appears to me that by discarding some useless lumber in the shape of pathological over-refinements, and by taking as general a view as possible of the whole subject, we may yet do much to narrow the problem, and to place ourselves face to face with it in its simplest form, shorn of all irrelevant matter—surely a by no means inconsiderable advantage towards its successful solution.

Taking first for our consideration the large class of malignant diseases denominated "alveolar carcinoma," with its principal subdivisions—scirrhus and encephaloid,—we are told that this is due to the proliferation of glandular epithelium in the meshes of a fibrous stroma, such stroma being firmly organised and most abundant in scirrhus, and comparatively scanty in encephaloid. Here the character of this stroma, and the emphasis laid upon it in pathological instruction, seem to me to obscure from our mental vision the essential and vital characteristics of the new growth. Some authorities consider it merely the original connective tissue of the part; others an entirely new formation; the most recent make an equally balanced compromise between the two. But I think that the prevailing impression in the medical mind is that this alveolar stroma is altogether a neoplasm, a characteristic and typical feature of the cancerous tumours. Let us now examine the correctness of this view, taking scirrhus as the most typical form of alveolar carcinoma and the female breast as its most ordinary seat. If we take a thin section from the normal breast, we see the bands of white fibrous tissue variously interlaced, so as to form irregular meshes; at intervals the acini of the gland lined by epithelium; here and there collections of adipose tissue. When the organ becomes affected by scirrhus, we find the epithelial cells of the acinus transgressing their boundaries, depositing themselves in the interstices of the normal connective tissue wherever they can gain a foothold, here proliferating abundantly and stretching the developing fibres, till in time these become atrophied or absorbed. In the last stage, as a rule, the cells greatly predominate; we then encounter only friable cell-masses, many of which have undergone caseous or fatty degeneration, with but a mere skeleton of the original fibrous tissues remaining.[2] On examining a section of the scirrhosed breast, we notice an acinar or alveolar distribution of the cell-masses, corresponding precisely to the normal arrangement of the fibrous bands, and in no way differing from it. When the section is through a plane parallel to the fibres, we find the cells apparently arranged in long thin rolls; when transverse, the cells appear grouped in larger or smaller irregularly roundish or oval clusters. Here and there some of the original acini of the gland remain, adding to the alveolar appearance.

But in order to find the most typical alveoli and the representation of scirrhous cancer most commonly given in pathological manuals, we must study the development of the cancer cells in fatty tissue. We here see these cells travelling from the affected part along the fibres of the reticulum; they locate themselves at the angles formed by the crossing of the different fibres and proliferate, crumpling up before them the fat-cell which each mesh contains. When the process is complete, the place of the fat-cell is wholly occupied by the malignant cells, and the original fibres of the reticulum remaining unaltered, the appearance presented under the microscope is that of large roundish acini. Throughout all this we utterly fail to find any development of new fibrous tissue. It cannot be denied that there may occasionally take place (as in other conditions of chronic irritative inflammation) some hypertrophic increase of fibrous tissue in the vicinity of a cancerous tumour; the skin of a cancerous breast often *seems* thickened, even to a long distance from the seat of disease. But this phenomenon is by no means constant, is of an accidental nature, and has nothing whatever to do with the alveolar characteristics of the neoplasm. The most careful examination of numerous cases has entirely failed to indicate to me that there is any increase of fibrous tissue whatever in ordinary cases of scirrhus, whether hypertrophic or of new formation. The gist of the whole process of development in scirrhous cancer of the breast appears simply to be that the cells of the acini, under the influence of some law at present very mysterious to us, proliferate abnormally, diffuse themselves through the adjoining tissues by the agency of lymph currents (probably also by their own amœboid movements), and grow vigorously wherever they can find room; but that their distribution depends strictly on the anatomical structure of the part, and proceeds on lines previously laid down.

I will pause here a moment to make one or two further remarks respecting the relationship of the white fibrous tissue to scirrhus, which we have just been considering; because I believe that many or most people look upon the characteristic hardness of a scirrhous tumour as due to the superabundance of such tissue in and around it, and perhaps at the first glance will not be able otherwise to account for the very marked induration which we almost always find. The fallacy of such an idea will, however, be obvious when we consider that a tumour composed wholly of white fibrous tissue has no such feature; still more so when we remember the soft pulpy character (in ordinary situations) of the growth we term "round-celled sarcoma" (which in abdominal organs I have seen not a whit more solid to the touch than condensed milk), and then reflect that this material, when enveloped by a rigidly resisting capsule, as in the case of the testicle, feels to us of stony hardness. A still more striking example is afforded by lympho-sarcomatous tumours, which, usually not particularly remarkable for their hardness to the touch, when growing under dense fascia in the lower part of the neck are commonly mistaken at first for an exostosis, then for osteoid cancer. The truth is, that the sensation to our hand of hardness occasioned ordinarily by scirrhus, and extraordinarily by the tumours just mentioned, results from the tension of cell-masses growing under or among the meshes of resisting non-elastic tissue. A similar explanation will account for the puckering of the skin, for the retraction of the nipple, and general tendency to shrinking and contraction in the adjoining tissues, most marked in the case of scirrhus, though by no means confined to this; the growing cell-masses haul on the fibres, somewhat in the same way as a sailor hauls on a rope.[3]

Next as to encephaloid cancer. We hear little of this nowadays. There is a fashion in pathology, as in most things else; and the present custom is to designate tumours which would formerly have been classed under this heading as "round-celled sarcoma." I venture to think that this is a great mistake; and that the latter term, implying as it does a connective tissue origin, is employed far too frequently at the present day. In the case of the female breast, I cannot but assign an *epithelial* origin to the tumours commonly termed "sarcoma," together with a certain degree of alveolar structure proportionate to the stage of the tumour and to the amount of fibrous tissue still remaining; and I therefore prefer for these the old and unfashionable term

[1] This paper constitutes part of a lecture introductory to the course delivered by the staff of the Cancer Hospital from January to March, 1886.

[2] This description, of course, does not refer to those exceptional chronic adstrophic cases in which the fibrous tissue is not eroded; though even here I should hesitate to call it hypertrophied.

[3] A familiar example of the enormous energy exerted by proliferating cell-masses—often in themselves soft, pulpy, and friable—must occur to all who have noticed the power with which colonies of young fungi elevate heavy slabs or stones overlying their bed; and we know how the algæ, growing on the lees of wine which has issued from a small leak in a cask, may eventually [redacted] cask up many inches.

"encephaloid."[1] These growths on section often remind one of pomegranate, the soft pulpy cell-masses being contained in coarse meshes of the connective tissue of the part, and their vascularity adds to the general resemblance. On inspecting a thin section of one of these, the brown bands of fibrous tissue will be seen in contrast with the dark-blue cell-masses. Under the microscope we find cells of pretty much the same character as the former; as a rule they are not quite so large or so well defined, but their growth appears to be far more exuberant. Instead of little detached knots of cells inserting themselves, as it were, painfully and with difficulty into the connective tissue meshes, we find huge masses; these are still contained in alveoli, only that the latter are now very large and coarse. The cell-masses at first keep within the bounds of the normal acinus of the gland—soon, however, transgressing this; they are evidently the results of proliferation of the epithelium appertaining to that acinus, and show no indications of any connective tissue origin.

The question now arises: If these two forms of cancer (scirrhous and encephaloid) both arise from the acinar epithelium, how is it that they are clinically so distinct—so that in the one case we find a tumour of stony hardness, in the other a growth comparatively soft, perhaps even fluctuating? The former is characterised by puckering and contraction, the latter by prominence and distension. I think we may find a plausible explanation of these peculiarities in the state of the white fibrous tissue of the individual patient. Those who have occasion to operate frequently on the female breast must have noticed, when proceeding to scoop out the contents of the axilla, the marked difference in the consistence of the normal tissues here situated—a difference by no means referable solely to age, but in great measure also plainly depending on natural habit of body: so that in one woman you may clean out the cavity with great ease; in another, not markedly distinguished from the former in age or general appearance, the fibrous tissues are exceedingly tough, and have to be divided by the knife or scissors. I would, then, refer the clinical and other differences between scirrhus and encephaloid cancer, as these affect the female breast, simply to differences in the resisting power of the white fibrous tissue in the individual who happens to suffer from the one or the other. In scirrhus, as a rule, the malignant cells force their way with difficulty, only gradually eroding their fibrous envelopes; in encephaloid, the cells prey, if I may so speak, on the surrounding fibrous tissue from the first, and there is no resistance, no pressure, no increase of tension, no feeling of hardness to the touch. I do not see how else to account for the facts, but I cannot venture, however, to offer the above hypothesis as more than provisional.

(To be concluded.)

[1] If carefully looked for, a typical scirrhous appearance may nearly always be found at some part of the section of these tumours, a point tending strongly to indicate an ide[illegible]

EPITHELIAL CANCER OF THE TONGUE LIP, AND UTERUS.

BY JOHN CLAY, M.D.,
PROFESSOR OF MIDWIFERY, QUEEN'S COLLEGE, BIRMINGHAM.

IT is now six years since I first communicated to THE LANCET (March, 1880) some observations, with illustrative cases, on the use of Chian Turpentine in the Treatment of Cancer. Much outspoken, not to say hostile, criticism of the remedy characterised the discussion which resulted from that communication. I have not troubled myself to enter upon this controversy, nor, with the space at my disposal, can I now venture to do so. I have been content to steadily pursue the treatment in the course of my own practice, and with such excellent results as to justify me in adhering to the statements I made in the paper above referred to. As the test of experience is the most conclusive reply that can be made to the criticisms and objections offered to my method of treatment, I now submit such evidence, in the form of brief notes on three cases of cancer, in different positions, each treated by Chian turpentine. I offer these, not as isolated examples, but as types of a number of successes obtained by similar treatment in cases alike as to their character and their situation. In the name of suffering humanity, I ask the medical profession to consider these cases without prejudice, and in the hope that the narration of them may lead to a more extensive and resolute trial of a remedy the high value of which I have tested and proved in my own practice.

CASE 1. *Epithelioma of the Tongue.*—On March 30th, 1885, I saw, in consultation with Mr. Bury of New Barnet, Mr. [illegible]—— of Shrewsbury, aged fifty-nine years, a gentleman retired from business. The medical gentleman in charge of the case informed me that the patient was suffering from epithelioma of the tongue, and that he had consulted two of the highest authorities in London, who had confirmed his diagnosis, and had pronounced the case to be unsuitable for operation. It was reported to me that one of the consultants confidentially expressed the opinion that the disease would probably prove fatal within two months. The disease was first noticed about four months previous to the above-named date. It commenced with soreness on the right side, at the junction of the root of the tongue with the floor of the mouth. There was some ulceration at this part, which was attributed to the irritation of a decayed tooth. The tooth was extracted, but the soreness and ulceration were not relieved, but gradually increased. The patient has never had syphilis. He has had caustics applied occasionally, and had taken sedatives to ease the pain. On examination, I found, in the situation above mentioned, an ulceration about the size of a sixpence, with a hardened and everted edge on the tongue side of it. There was a row of raised shot-like epithelial growths (not in a state of ulceration) proceeding from the ulcer on the lateral border of the tongue, and running forwards towards the tip for about three-quarters of an inch. The tissues around the ulceration and growths were thickened and hard from cancerous infiltration. There was an enlarged submaxillary gland about the size of a pullet's egg. The movements of the tongue were limited and painful. The patient was well nourished, but depressed and anxious. I gave an unfavourable prognosis, but thought it was a case in which Chian turpentine ought to be perseveringly tried, as that seemed to be the only alternative left to him. He was ordered the following mixture: eight ounces of Chian turpentine (Southall's) and two drachms of resorcin, two teaspoonfuls three times daily; and to have the ulcer and growths slightly painted on alternate days, respectively with chromic acid solution (ten grains to the ounce) and solution of perchloride of mercury (one grain to the ounce). On April 16th, 1885, Mr. Bury wrote to me thus: "There is no arrest of the glandular enlargement, which, if anything, is somewhat more marked. The ulcer in the tongue about as before. I presume we must not lose all heart because the remedies do not seem to have arrested the disease; possibly sufficient time has not elapsed since the commencement of the use of the medicines." On June 30th he again wrote to me, and in reference to this point stated that "about a week after your reply to me the enlargement of the glands began to disperse, and in about three weeks it was entirely gone. The ulcer of the tongue is, I believe, quite healed." I mention these facts, as it is a too common error on the part of medical men to imagine that the remedy is useless because its effects are not apparent in a few days. I did not see the patient again until July 10th, 1885, when I was surprised to find him looking so well. As I had heard nothing of him I feared that he had succumbed to the disease. On examination I found the enlarged gland had disappeared; the tongue could be moved freely and without pain; on the right side it looked and felt quite normal, as though it had never been affected. On the left side of the neck, however, I discovered an enlarged gland, and on the lateral border of the tongue on the same side I found an epithelial growth of the size of a hazel-nut in a sloughing condition. The remedies were ordered to be continued as before. I saw the patient about a month afterwards. The newly discovered growth had all but disappeared, and a month later I found the parts free from disease. The medicine was directed to be taken in diminished doses, and the local applications to be discontinued. I saw him in December of the same year, when he was quite well and proposed spending some weeks on the Continent. I quote the following remarks on the case from a letter from Mr. Bury, the medical gentleman already referred to: "You will be greatly pleased with the success of your remedies, which have restored to life, one may truly say, under God's blessing, one doomed to die in the course of a few months."

CASE 2. *Epithelioma of the Upper Lip.*—Mrs. [redacted], aged fifty-two years. General health good; has had four children, but no miscarriages; never had syphilis; menopause about eight years previously. She consulted me on October 20th, 1883, at the Queen's Hospital, ostensibly for a vaginal discharge, but really for a growth occupying nearly the whole of the upper lip and involving the lower portion of the left ala nasi. She had been under the care of Mr. W. Freer, who had advised its removal. It presented a fungating raised appearance, and was irregular in outline. The surrounding tissue was hard to the touch, and the cancerous infiltration extended some distance around the nodule. A small portion was excised by scissors, and examined by the resident physician and resident obstetric surgeon under the microscope, in the fresh state, and well-marked "epithelial nests" reported. On account of the occasional hæmorrhages, the growth was painted over once with perchloride of iron solution, and afterwards dressed with vaseline. The *simple* Chian turpentine mixture was ordered to be taken three times daily, in two-teaspoonful doses. The patient presented herself regularly every fortnight at the hospital, and at the end of ten weeks the mass had shrunk considerably, and had a black appearance; the infiltration had disappeared, and she was now free from pain. In the twelfth week the mass felt loose, but it was not interfered with. Thirteen weeks from the commencement of the treatment, on getting up in the morning, the patient found that the mass had separated during the night. The lip was free from hardness, and movable. There was a white cicatrix about the size of a shilling, and a slight notch in the margin of the lip. I saw her on August 16th, 1886; she was quite well, and there had been no recurrence of the disease.

CASE 3. *Epithelioma of the Os and Cervix Uteri.* Mrs. W —, aged fifty-four years. Very feeble and emaciated, and cachexia well marked. Could not walk a hundred yards even with assistance. Has had very profuse watery and sanguineous uterine discharges for several weeks. Mr. L. Bair, who had seen her previously, had, she stated, pronounced the case to be uterine cancer, and incurable, and that she could not live a fortnight. On examining the uterus, a mass of epitheliomatous cancer, about the size of a hen's egg, occupied the upper part of the vagina, but believed to be limited to the uterus; it bled freely from the examination. I ordered the Chian turpentine mixture with resorcin, and directed her to use vinegar-and-water injections. At the end of seven weeks the hæmorrhage and leucorrhœal discharges had nearly ceased, and the patient could now walk more than a mile twice weekly to see me. The growth had almost disappeared. At the end of five months she had increased 1½ lb. in weight. About the seventh month she had an attack of facial paralysis affecting the right side, which probably arose from cold. She recovered almost completely. Now (a year and a half from the commencement of the treatment) she can attend to her household duties as well as she could before her illness. The growth has cicatrised completely. There is a small nodule, which appears to be healthy, and represents the os and the cervix of the uterus.

Birmingham.

TROPICAL ABSCESS OF THE LIVER.

BY SURGEON A. TOMES,
INDIAN MEDICAL SERVICE.

(Concluded from page 665).

WITH regard to the treatment, there are two drugs which are eminently useful in the presuppurative stage of hepatitis—ipecacuanha and chloride of ammonium. The use of the former, advocated by Professor Maclean, in the same large doses as for acute dysentery, has proved of the utmost value in reducing sthenic hepatitis of Europeans. I prefer the latter for natives, in doses of from fifteen to twenty grains, combined with quinine and hydrochloric acid. Experience having taught us the immense risks to life that attend the plan of non-interference when an abscess has formed, and knowing also that the prospect of a cure by operative treatment depends largely upon the stage at which it is undertaken, our utmost attention must be paid to the early detection of pus. So soon as there is any suspicion of suppuration the liver must be explored; there is no need to wait for the abscess to declare itself. It is now a routine practice among surgeons in India to explore the liver with a long fine needle or trocar. The instrument, which may be attached to an aspirator, is plunged into the organ towards the suspected seat, and even when no pus is found no evil result has ever been known to follow. On the contrary, the acute symptoms are generally relieved by the procedure. I have heard of practitioners who puncture not merely for an exploratory purpose, but as a curative measure, in acute hepatitis.

In advanced cases there may be no difficulty of diagnosis. There will be a large, tense, fluctuating swelling occupying the hypochondrium. Actual pointing is rare, and in all cases where there is any doubt the aspirator should first be employed to determine the presence and position of the abscess. Supposing pus to be detected, the rule is to evacuate. Thirty years ago, heavy as the mortality from unrelieved ulcer was known to be, surgeons hesitated to interfere. They preferred to wait in hopes of a cure by natural processes. Results of operation were most unfavourable, because it was undertaken too late, and because entrance of unpurified air produced septic decomposition. They never operated unless the abscess came to the surface and distinctly fluctuated. With earlier detection, improved instruments, and antiseptic precautions, operation is followed by a greater measure of success in modern times. Still, the circumstances attending the formation of an abscess in the liver are such that the proportion of recoveries will always be small. The disease is the outcome of a constitutional affection; there is a tendency to complication by bowel complaint and to multiplicity. Effect of climate can be met by removal to Europe. Multiplicity cannot usually be detected during life. One abscess may be successfully opened and drained, while another, a deeper one, bursts internally and destroys life.

In the absence of a sufficiently extensive and complete series of cases, where all results are given, the failures as well as the successes, it is impossible to estimate accurately what greater degree of success attends operative interference at the present time. It appears that formerly the mortality was little, if at all, lessened by operation. In the 81 cases collected by Dr. Waring (1862-52), the cures were 15, or 18·5 per cent., but he distinctly admitted that the proportion was much overstated, the cases having been in a great measure selected for report. As far as I have been able to make out from a study of 126 unselected cases operated on in recent times, the recovery rate is now about 22 per cent. Taking small series, the results are very variable. In one series of 9 operated on in a Calcutta hospital, 1 only was cured. In another series of 14, 8 were cured. Surgeon-Major (now Brigade-Surgeon) Curran[1] collected 24 cases, with 4 recoveries. Of the 8 cases in "Murchison's Clinical Lectures," 3 were cured. In my own, 20, all natives, the recoveries were 5, or 25 per cent.

The diagnosis of an abscess having been confirmed, there are two methods of dealing with it—the open and the close. The close consists in emptying the sac by a single or several aspirations at intervals, until it becomes obliterated. The open method means the establishment either by the knife, or by an ordinary trocar, of a permanent opening, and draining off the contents until that same end is attained. Formerly there was no choice; the open method was the only one available. When the aspirator was invented some sixteen years ago, it was hoped this would mark the commencement of a new era in the history of the treatment of liver abscess: difficulties would now be overcome, all risks avoided, and evacuation effected with certain success. These expectations, alas! have not been realised in full. As an instrument for diagnosis the aspirator has proved invaluable. But it is found that only a certain number (the smaller proportion) of abscesses suitable for operation can be cured by aspiration alone. Cases occur over and over again where the cavity speedily refills as soon as emptied, and the open has to be substituted for the close method. Aspiration, by causing centripetal tension on the walls, appears to favour the refilling of the cavity. At least two-thirds of all cases that have been cured by operation have been treated on the open method. In my opinion a cure should always be attempted by aspiration, for this method is the more agreeable to the patient, while the risks of septicism are avoided.

[redacted] Gazette, 1880.

Moreover, it is far more rapid. If the case is capable of cure at all by the close method, it is cured promptly after one or two tappings, while the open is always a tedious business.

Abscesses of small or medium size, and limited by a distinct wall or membrane, also quiescent abscesses, are those most likely to be cured by aspiration. Cures have resulted after a single aspiration of as much as 16 oz., 30 oz., and in one remarkable case 112 oz. of pus. This last would be scarcely credible were it not for the established reputation of the author, Professor McConnell, of Calcutta. The operation may need repeating a second or even a third time, but when it is necessary to tap oftener than that, my experience is that the establishment of a permanent drain is called for. In operating by this method, it is a question whether the abscess should be completely emptied or not. I am in favour of partial evacuation in any but small collections, to aspirate slowly, and to desist as soon as the fluid runs with difficulty. The liver cannot so contract upon a large cavity as it is emptied as to effect its obliteration. A vacuum results, to fill which there is a rapid reaccumulation of fluid (pus, broken-down tissue, and exudation from the vessels). A guide as to the advisability of persevering in the close treatment in any case will be afforded by the character and quantity of the contents, and by the temperature range. If the contents are proved to have become of the uniform yellow character of laudable pus, that indicates the cessation of the breaking-down process and the formation of a limiting membrane. In aspirating, it is best to use the largest-sized trocar, because liver pus is apt to be so thick, tenacious, and shreddy. Having discovered its presence by the fine explorer, that may be left *in situ* as a guide. The larger trocar is then fitted and introduced along it, having first incised the skin with a scalpel to facilitate its entrance, and to avoid an unpleasant or even dangerous jerk. The operation is not painful, except at first, when the skin is perforated, but it is one that patients usually very much dread. On one occasion the patient suddenly flinched before the instrument even touched him, with the result of internal rupture and death. Since reading that account I have been in the habit of giving chloroform. Local anæsthesia by cocaine might answer. For establishing a free opening some prefer the knife, but a large trocar is usually employed. The skin having been incised, the trocar is boldly slid along the exploring needle (Sir J. Fayrer's grooved needles offer great advantages for this purpose) to the required extent. If no guide is used, the cessation of resistance will indicate that the cavity has been reached. It is advisable to leave the cannula *in situ* for a few days, to allow of adhesions forming, otherwise the organ may shift its position on its removal, when the reintroduction of a tube will be difficult and free escape of pus prevented. Subsequently a drainage-tube is substituted for the cannula, and its end received into a bunch of absorbent dressings. Post-mortem examinations show that adhesions do not always exist, though they are generally found. The risk of extravasation has, however, been exaggerated, and the tendency of modern surgeons is to disregard the point in determining the period for operation. Where no adhesions exist at the time of operation, if a tube be left in the wound, lymph is very soon thrown out around it, shutting it off from the pleural or peritoneal cavity through which it passes. It has been found completely isolated by the second day. The drainage-tube should not have lateral perforations throughout its length—granulations from the walls of the sinus in which it lies are apt to sprout into them and prevent its extension in the process of contraction of the cavity. One or two large holes near the end are all that is necessary.

Which is the best site for opening an abscess? As a general principle, the puncture is to be made where pus can be most readily reached, as indicated by fluctuation or by exploration. But whenever a choice is permitted, it is advisable to open *below* the ribs, for these reasons: 1. An opening in the intercostal space is apt to become obliterated on the collapse of the liver by the falling together of the ribs; this may necessitate excision of a portion of one or more to preserve patency of channel. 2. If a soft rubber tube be left in, it is liable to be compressed by the approximation of the ribs, and escape of pus will be interfered with. 3. If a stiff cannula be left in, it may, by its irritating pressure, excite periostitis, and even necrosis.

When every has follo[illegible] spontaneous external bursting an abscess, th[illegible] always below the ribs, generally in the epigastrium, in the neighbourhood of the ensiform cartilage. When an abscess bursts through the thoracic wall recovery is rare; death is preceded by necrosis of ribs and sloughing of integument (Maclean). Thus nature clearly indicates the best route for evacuation. Statistics also show that better results attend operation below the ribs. Out of ten abscesses tapped between the ribs eight died and two recovered, or at the rate of 20 per cent.; out of twenty-two tapped below the ribs twelve died and ten recovered, or at the rate of 45·4 per cent. For aspiration the same rule does not apply. It is dangerous to aspirate towards the extreme upper and lower borders of the enlarged organ, for on removal of the trocar (the largest is used) there probably will be nothing to prevent extravasation of pus or blood. The liver contracts and alters its relation to the parietes in those directions. Extreme limits should be avoided, but there is little risk if aspiration is performed in the region where the organ is in constant contact with the chest wall, and there is no fear of necrosis after aspiration through an interspace.

It is scarcely necessary to say that the most stringent antiseptic precautions must be observed. It is impossible to prevent the entrance of air under the open method, but it can be rendered harmless by filtration through an antiseptic medium. In any case the accident is less dangerous where there is a free exit for its escape than where the cavity is sealed up. A large abscess will discharge an enormous quantity of matter, and the dressings rapidly get soaked, so that it is a difficult thing to keep the patient clean, and the decomposition of the discharges in the dressings is a great source of danger, especially in the tropics. With regard to washing out the cavity, as long as the pus keeps sweet this is unnecessary. Irrigation does not diminish the amount of discharge, but rather tends to increase it by its irritating effects on the walls.

I especially recommend for adoption the excellent method of dealing with abscess of the liver on the open method devised by Dr. Patrick Manson of Amoy.[2] By his plan the risks of extravasation of pus or blood where no adhesions exist, and of septic infection from decomposing discharges or entrance of foul air, are avoided; while at the same time the cavity is perfectly and constantly drained, and the patient maintained in a condition of comfort and cleanliness throughout. Having employed it, I can testify to its great value and convenience. The apparatus consists of a large trocar and cannula; a piece of drainage-tubing eight or ten inches long, of a diameter rather larger than that of the cannula; six feet of indiarubber tubing, half an inch bore, one end being fitted with a silver tube two inches long, fixed in the centre of an antiseptic pad; and a piece of waterproof sheeting. The calibre of this silver tube is such that the end of the drainage-tube can be easily and accurately fitted into it; the other end of the six-foot tubing is fastened within a small wide-mouthed phial placed in a large wide-mouthed jar. The jar, phial, and tube are filled with antiseptic solution, and the tube is clamped at its ends. The abscess is tapped with the trocar, and while pus is flowing the drainage-tube, previously stretched on a staff to reduce its calibre, by tying its distal end over a cap or with a piece of catgut, drawing in its proximal end and fastening it with string to the eye of the staff, is then slipped through the cannula to the full depth of the cavity. The cannula is withdrawn over the stretched tube; the tube is then released by cutting the string, and immediately springs to its full diameter, thus completely filling up the openings in the liver and parietes, and bridging over any interval that may exist between them. The free end of the drainage-tube is inserted into the connecting silver ferrule. A flannel binder is applied around the chest above and below the tubes and the pads and waterproof, to keep the apparatus in place. The clamps are removed from the long tubing, and its syphoning action set going. The contents of the abscess pass into the small phial, which is kept submerged in the solution in the jar, and thus acts as a trap. The jar is placed on the floor at the bedside, and is emptied and refilled from time to time as occasion requires. The length of the tube allows full play to the movements of the patient. After a day or two, it is found that the drainage-tube is no longer firmly held; it will have dilated the opening by its presence, and will lie loosely; any discharge that may now escape at its side will be caught up in the antiseptic dressings under the waterproof. By this

[2] Medical Reports of the China Customs Gazette.

time a wall of lymph will have formed around it, shutting it off from the visceral cavity.

Whenever an abscess is being drained, it is important to remember the necessity of shortening the tube from time to time as the cavity contracts. I have known an abscess close in around an unshortened tube until at last the latter came to lie in a mere sinus of a length corresponding to the depth of the original cavity. The walls of the sinus continued to secrete pus, and this led to a false impression as to the progress made, until lateral exploration with a probe at once revealed the true state of affairs.

Shepherd's-bush.

ON RECURRING VENOUS THROMBOSIS FOLLOWING CHRONIC PYELITIS OF GONORRHŒAL ORIGIN.

By H. FRENCH BANHAM, M.A., M.D,
PHYSICIAN TO THE ROYAL BERKSHIRE HOSPITAL.

W. G. ——, aged thirty-four, was admitted into the Royal Berkshire Hospital, under my care, in October last, with symptoms indicative of chronic pyelitis. For the early history of the illness of this patient I am indebted to Mr. A. J. Moore. Coupling the facts given to me by him with those ascertained from the patient, there can be little doubt that in June of last year he had an attack of gonorrhœa, followed by inflammation of the prostate gland and retention of urine, necessitating the occasional passing of a catheter. Subsequently he had cystitis, with frequent and painful micturition; and some time afterwards he began to experience severe pain in the region of the right kidney. On his admission to the hospital all symptoms of cystitis and prostatitis had disappeared, but there was considerable pain and tenderness on pressure over the right kidney, and he was passing acid urine mixed with a large quantity of pus and a few oxalate-of-lime crystals and blood-corpuscles. Notwithstanding rest and careful dieting and the administration of certain remedies, the case underwent no material change until the beginning of January last, when he experienced some sharp pleuritic pains in the right side, and there were the accompanying physical signs of a localised dry pleurisy. These shortly disappeared. There was then great tenderness over the liver, which descended a little below the margin of the ribs. During the period of these additional symptoms there was some little pyrexia and constitutional disturbance. On Jan. 16th he had shivering, was seized with severe pain in his right leg, and when seen by me in the evening of the same day his temperature was nearly 103° F., his pulse was rapid, and he appeared to be exceedingly ill. The leg was then much swollen, and the whole of the long saphenous vein exquisitely tender and quite hard. The man was suffering so much that no further examination was made at this time than was necessary, with the view of affording him as much relief as possible. The next morning it was observed that there was tenderness extending quite up to Poupart's ligament, but no induration of the vein was noticed above the saphenous opening. After a few days the case began to assume a less serious aspect, but on the 25th there was a repetition of the symptoms that had set in on the 16th, the veins of the left leg being affected in the same way as those of the right had previously been. In this second seizure the pyrexia and pain were less. In the case of both legs the swelling and œdema affected the foot, leg, and thigh, almost up to the saphenous opening; but above this the integument appeared to be normal. The two attacks above recorded would have appeared entirely unconnected the one with the other but for the circumstance (ascertained on inquiry subsequently to the second seizure) that in the week intervening between the commencement of the two attacks there had been for a short time considerable enlargement of the penis and difficulty in micturition. For a week or two the patient continued in a most precarious condition, with a feeble and rapid pulse and general febrile symptoms. In a short time, however, his state became substantially the same as on admission, the urine having the same character, but the tenderness in the right flank had almost disappeared. The superficial epigastric, circumflex, iliac, and other superficial veins of the abdomen, as well as some of those in the leg, were now conspicuous by their distinctness, and the long saphenous vein, and even its tributaries on the dorsal and inner side of the foot, still remained hard and cord-like. He left the hospital in the beginning of March, and I have ascertained that for a time his general health continued to improve, but he was afterwards attacked by thrombosis of the veins of one arm, full details of which have not, however, come to my knowledge.

Some of the conditions in this case were not so closely observed as they should have been; it is possible, however, that under any circumstances there might have been some difficulty in interpreting them. The sequence of gonorrhœa, cystitis, prostatitis, and pyelitis no doubt actually occurred. In regard to the thrombosis and endophlebitis, it is not clear which was cause and which effect; both existed on the evening of Jan. 16th. Attention was chiefly directed to watching for its upward extension, and the sudden appearance of the same condition, or at least of thrombosis, on the left side was wholly unexpected. I am inclined to think that thrombosis of the right long saphenous vein first occurred; that it was soon accompanied by endophlebitis; that the thrombosis extended so as to involve the right common iliac vein; that the prostatic plexus was then implicated; and so the mischief passed to the other side. These, however, are matters of conjecture. But it is curious to observe the great tendency to thrombosis that seemed in this case to exist, and which occurred, apparently, not as the result of feebleness of circulation, for the pulse was good and the patient not greatly prostrated, but, as it were, from some special condition of the blood, perhaps caused by the long-continued deteriorating influence of a purulent discharge, reducing its albumen and leaving the coagulable element in comparative excess.

ST. THOMAS'S HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF THE OCCIPITAL BONE; TREPHINING; RECOVERY.

(Under the care of Mr. SYDNEY JONES.)

THE following is an example of that class of injury which has been extremely benefited by the application of the principles of antiseptic surgery to its treatment. There are few cases in which greater advance has been made than in these, as will be readily acknowledged by any surgeon with a knowledge of the results of practice in this department of surgery during the last twenty years. In injuries such as that recorded it is of course impossible to prepare the patient as carefully as before exploration of the brain for tumour, neither is it possible to make the incision as now recommended, whilst often the presence of foreign bodies introduced by the instrument which inflicted the damage is a serious source of danger. That it is, however, possible with care and skill to secure immunity from spreading inflammation of the meninges and other local complications is well proved by this as by other cases which we have published. For notes of the case we are indebted to Mr. Sansom, dresser.

J. N——, aged fifteen, a cabinet-maker, was admitted on June 18th, and left on Aug. 13th, 1886. The patient was brought in about a quarter of an hour after the accident. He was stooping down to pick up some money, when a swing boat struck him with much violence on the back of the head. He was knocked down and rendered insensible, and was bleeding from a cut on the back of the head when picked up.

When examined at the hospital the lad was found to be almost insensible, it being only possible to partially arouse

him by shouting to him, when he would put out his tongue and make some unintelligible answer. The pupils were unequally dilated, the right being the larger; both acted to light. The conjunctivæ were sensitive. The surface of the body was pale and cold, and there was slight sweating. The pulse was rapid, somewhat feeble and irregular. There was no stertor. The limbs were flaccid. Soon after admission the patient began to move his head from side to side, moaning occasionally. He vomited at frequent intervals, but the vomit contained no blood, nor was there any from either nose or ear. There was a lacerated wound in the occipital region, to the left of and slightly above the external occipital protuberance, about an inch and a half from before backwards, and nearly parallel to the long axis of the head; and on the introduction of the finger into this an irregular depressed fracture of the bone could be felt. This measured three-quarters of an inch from before backwards, and half an inch from side to side. The edges were sharp and irregular, and the depressed bone could be felt at the bottom of it.

About two hours after the injury Mr. Sydney Jones trephined, the patient being under the influence of chloroform. Two trephine openings were required, and from these the splintered bone was elevated and removed. The internal table was found to have been splintered to the left and behind, and a sharp spicule of bone was found driven in between the dura mater and the bone, pressing on the dura mater, but not causing any wound. The wound was carefully closed with catgut sutures, a drainage-tube inserted, and the wound dressed with dry iodoform gauze, the head being carefully bandaged. Before the operation the head was shaved and washed with a 1 in 20 solution of carbolic acid, whilst during the operation the spray was employed. His temperature at midnight was 98°.

June 19th.—He was very restless during the night, never dozing for more than ten minutes together. Has to be constantly watched to keep him in bed. Vomited at 6.30 this morning after taking a teaspoonful of milk. He has not passed urine, nor have the bowels acted, although five grains of calomel were given last night. When spoken to he complains of headache, and has asked for the urinal, which he has not used. He always lies on the right side, with his eyes closed and the limbs flexed. Face flushed; eyes bright; pupils normal. Pulse rather full, 100; temperature normal. Some blood came through the first dressing, which was renewed at 2.30 A.M. Bowels acted freely in the afternoon.

21st.—He passed a restless night, but seems quieter this morning. He has vomited at times since the operation. Has retention of urine, which is relieved by the catheter.

22nd.—Complains of hunger, but is still only allowed to have milk. Pulse 80, fairly strong and regular. No sickness. Will now lie on either side.

23rd.—Was restless during the early part of the night. Pulse weak and dicrotous. Tongue moist and slightly furred. Wound dressed: very slight healthy discharge.

25th.—He has much improved; sleeps well at night, but requires the use of a catheter at regular intervals. Wound dressed and drainage-tube removed.

July 1st.—Since the last note the wound has been dressed daily, but is now almost healed, there being but slight discharge from a small aperture about a quarter of an inch in diameter. He is still restless both night and day, and cannot be left alone on account of his attempts to get out of bed. The left pupil is slightly the larger; he has no headache, and he eats ravenously.

On the 19th the temperature in the evening rose to 101·2°. It did not afterwards reach this, there being a rise of one or one and a half degrees above the morning temperature until the 25th, when it became normal both morning and evening.

A month later the patient left the hospital. The wound was quite healed, though the depression due to the removal of the bone was very evident. He was fitted with a leaden plate to protect this.

WOLVERHAMPTON GENERAL HOSPITAL.

TWO CASES OF ACUTE GLOSSITIS.

(Under the care of Dr. TOTHERICK.)

FOR the following cases we are indebted to Mr. W. H. Evans, M.B. Lond., house-physician.

CASE 1.—E. R——, aged twenty-one, was admitted on July 12th, 1886. Tongue covered with thick brown fur, hard, and immensely swollen, projecting half an inch beyond the teeth; it lies immovably fixed in the mouth; causes great pain, and is very tender on pressure. Salivation profuse. Breath extremely offensive. There is very little swelling in the floor of the mouth, but considerable pain on pressure both here and at the angle of the jaw. Movements of head and neck are attended with slight pain. Articulation impossible. Deglutition very difficult. Patient complains of headache, and feels generally ill. Pulse slightly increased in frequency. Temperature 100·4°. Ordered milk and beef-tea, one ounce of saline aperient mixture three times a day, and a weak solution of permanganate of potash to wash out the mouth. The man can give no cause for his condition, but thinks he "caught cold."

July 13th.—Temperature normal; pain much less, but no apparent diminution in the size of the tongue.

14th.—Tongue much smaller; temperature normal; salivation less troublesome.

15th.—The tongue has almost gained its normal size. Patient feels much better.

He made complete recovery, and was discharged on July 17th, 1886.

CASE 2.—J. P.——, aged twenty-seven, was admitted on July 23rd, 1886. The patient was seized with sudden swelling of the tongue on the 21st, caused by "catching cold." Towards the same evening he complained of pain and swelling in the floor of the mouth, gums, and at the angle of the jaw. The pain has increased in intensity and the swelling in extent during the last forty-eight hours. He has been out of work several weeks, and denies any excessive indulgence in drink.

On admission the tongue was hard, and painful on pressure, covered with a thick fur, and protruded about three-quarters of an inch beyond the teeth. Salivation most profuse and distressing. Odour of breath not very offensive. Has great dysphagia, and can only swallow fluids, which have to be poured to the back of the throat. Articulation impossible. Respiration not impeded, although the dorsum of the tongue almost meets the roof of the mouth. Temperature 99·8°. Pulse 116. Urine: sp. gr. 1030; contains a trace of albumen. Ordered milk and beef-tea; also one ounce of saline aperient mixture three times a day, and a lotion of Condy's fluid for the mouth.

July 25th.—Temperature 102·2°. There is some superficial sloughing of the gums and under part of the tongue. Has had scarcely any sleep since admission. An incision about an inch and a half in length and a quarter of an inch in depth was made on each side of the median line of the tongue. Towards evening he felt much relieved, the temperature having fallen to 99·4°.

26th.—Swelling of tongue subsiding; has much less pain, and has slept fairly well since the incisions were made. Salivation still troublesome.

27th.—Tongue slightly swollen and indented by the teeth. Made a good recovery, and was discharged Aug. 1st, 1886.

Remarks by Mr. EVANS.—All observers admit this to be a rare disease. In his clinical lectures, Dr. Graves, referring to a case he had attended in his private practice, remarks as follows:—"True idiopathic glossitis is an extremely rare disease. J. P. Frank only saw one case during his whole life. Four cases of it have been observed of late years in different parts of Europe, one of which is given in a German journal on the authority of my friend, Dr. Gattel, of Elbing, a gentleman upon whose accuracy implicit confidence may be placed." After making a careful survey of the literature of the subject, I can only find sixteen cases, exclusive of the two above described, which are reported at any length. In the course of my reading I had come across descriptions of a few others, but of so fragmentary a character that it may fairly be questioned whether the cases to which they referred were undoubted examples of this disease. From a study of the cases lately admitted into this hospital, the onset of the disease is very sudden, enormous swelling of the tongue coming on in a few hours. There may be a little premonitory pain and stiffness about the angle of the jaw, with slight difficulty in mastication and occasionally pain in the occiput and neck, and then the swelling of the tongue follows with great rapidity. The organ may almost fill the cavity of the mouth, and in some cases project beyond the front teeth as much as "two inches." The tongue now lies motionless, is hard and painful on pressure, and coated more or less thickly with a brownish-white fur. Sometimes it is deeply indented by the teeth, especially on the inferior surface of the tip. Articulation is imperfect, and in some cases absolutely

impossible. Salivation is generally a prominent symptom, and causes great distress; the saliva, constantly dribbling over the surface and along the sides of the tongue, becomes viscid and ropy unless immediately wiped away. In severe cases the salivation may be profuse, and it constitutes to my mind one of the most distressing symptoms. Swallowing becomes extremely difficult, and in many cases fluids have to be passed to the back of the throat; even then the attempt at deglutition may set up violent fits of coughing. The inflammatory process may be strictly limited to the tongue, but does occasionally spread downwards to the rima glottidis and larynx, causing such serious obstruction to respiration that tracheotomy offers the only chance of escape from asphyxia. The temperature is usually slightly raised, but seldom runs higher than 102°. If no active treatment has been adopted, the tongue, having remained in this enlarged and painful condition for a variable period, from a few hours to a few days, commences to subside; and this sometimes occurs with great rapidity, being reduced to half its bulk in twenty-four hours or less; but usually a more gradual resolution takes place, and seven or eight days may elapse before the tongue has attained its natural size. Although the natural tendency of the disease is towards resolution, this happy termination does not invariably occur. It may go on to chronic induration or end in chronic glossitis. Several cases of hemiglossitis resulting in imperfect resolution have been recorded, one half of the tongue, remaining perceptibly larger than the other; one such case is mentioned by Dr. Graves, who states that in spite of his deformity the patient was able to speak perfectly. I am not aware of any case in which the glossitis was bilateral that is said to have terminated in a permanently enlarged tongue, but surely it is not unlikely that such an event might occur. We should not easily perceive it, as the advantage derived from a comparison of the two sides of the tongue available in cases of hemiglossitis would of course be lost. Another termination of acute glossitis is in suppuration, which may be diffused or circumscribed; the former variety rarely occurs. However, one case, in which death occurred from laryngitis, was recorded by Mr. J. Z. Lawrence, where the hyoid muscles and root of the tongue were infiltrated with purulent material. But the circumscribed form seems to be more common. Three out of the above-mentioned sixteen cases were followed by a circumscribed accumulation of pus; in two cases it was situate towards the root of the tongue. Recovery quickly followed evacuation of the pent-up matter. Gangrene may take place, but this is an extremely rare occurrence. One case of sphacelus of the tongue is reported by Mr. A. Pritchard, but the evidence that this was preceded by acute inflammation does not seem to be sufficiently clear. The diagnosis in general presents no difficulty; the enlarged tongue, profuse salivation, and other symptoms of the disease are characteristic. Nevertheless, in a paper published in the *Practitioner* some months ago, Dr. S. Mackenzie described some conditions liable to be mistaken for it, amongst which were salivary calculus, acute ranula, and abscess in the floor of the mouth. Most writers consider acute glossitis to be a strictly catarrhal affection; Mr. Butlin, Dr. Mussy, and Sir Dyce Duckworth are quite agreed upon this point. In two of the above eighteen cases it succeeded a "pharyngo-laryngitis," in one it followed "erysipelas and sore-throat," and in another the patient was being treated at the time for acute rheumatism. In the majority of cases the patients attribute their illness to "catching cold." It occurs more often in men than women, and chiefly in young adults, although in one of the above-mentioned cases the patient was eighty years of age. It generally affects both sides of the tongue; out of the eighteen cases it occurred eleven times bilaterally and six times unilaterally (in four instances on the left and in two on the right side), and in one case it attacked each side of the tongue in succession, being first on the left and afterwards on the right side. In a case of hemiglossitis reported by Mr. Bellamy, in which both sides of the tip were affected, attention is drawn to the fact that the median septum is thick and strong posteriorly and mesially, but thin and delicate towards the tip, and it is suggested that in cases of hemiglossitis which become general the inflammatory process may probably extend from one side of the tongue to the other through the thin part of the septum at the tip. With regard to treatment little need be said; it is very simple. The less severe cases usually subside in a few days, no active interference being necessary. The diet should consist entirely of slops; a saline aperient is generally indicated; and the mouth may be washed out with a disinfectant lotion, a weak solution of permanganate of potash answering the purpose very well. In the more severe cases, it is the general opinion that incision of the substance of the tongue is the correct mode of treatment; it relieves tension, diminishes the risk of sloughing, and certainly alleviates the pain.

GREENOCK INFIRMARY.

A FEW NOTES ON THE SYMPTOMS AND TREATMENT OF THE VICTIMS OF THE DISASTER AT CRARAE.

(Under the care of Dr. FOX.)

FOR the following notes we are indebted to Mr. Alex. D. Pithie, assistant house-surgeon.

On Saturday, Sept. 25th, a large number of excursionists went by steamer to witness the explosion of seven tons of gunpowder at Crarae quarries, Lochfyne-side. These quarries are situated on the side of a hill, and form a large bowl with only a narrow entrance. After the explosion the excursionists landed and walked to the quarry, about a quarter of a mile off. No sooner had they entered the bowl of the quarry than they began to stagger and drop down in all directions. With difficulty they were brought out, when it was found that six were dead and a great number unconscious. Eventually all of them recovered under the treatment used by medical men on the spot, except seven, who were sent to this institution.

On admission, all but one were found to be comatose. This patient had been violent, but could now be induced to keep to bed by gentle coaxing. The general symptoms were as follows:—The breathing was slow, deep, and stertorous (in the fatal case it was short and shallow, with stertor). The faces were flushed, and the veins on the neck and forehead distended. The eyelids were closed, and the pupils in every case were dilated on admission (in the fatal case these contracted just before death), but responded to the stimulus of light. The extremities were cold. There had been involuntary evacuation of the bowels in every case. As to the bladder, it was impossible to come to any conclusion, but on passing the catheter only a few ounces of urine could be drawn off. There was a very strong odour from the breath of each patient, which might be described as sweet-feculent. The pulse in each case was slow, but full and regular. All the temperatures were at first subnormal. The patients were all unable to swallow.

When admitted, the sufferers were at once stripped and put to bed; sinapisms were applied to the extremities, nape of neck, and spine; hot bottles were placed between the legs and along the thighs and side, also to the feet; the catheter was passed, and the urine drawn off. The bowels were first cleared out by a purgative enema of castor oil and turpentine, and afterwards stimulant enemata of beef-tea and brandy administered at intervals of about three-quarters of an hour. Friction was applied to the extremities and body. In the fatal case, ether was given hypodermically when the pulse began to fail (which it frequently did), with the effect of temporarily restoring the heart's action. The tongue was drawn forwards, and strong friction used to the chest and sides. Ammonia vapour was tried, also galvanism along the spine. These means were, however, of no avail, as the patient died of syncope about 9 A.M. on the 26th. Just before death very strong reaction set in. There was very profuse perspiration, the pupil contracted, and the temperature rose to a little over 101°. The peculiar odour of the breath was noticeable in every case, also the involuntary evacuation and dilated pupils. As to the bladder, it was impossible to say anything about the involuntary micturition, inasmuch as, although their clothes were wet, this might be attributed to the very heavy rain which fell at the time. All the temperature being subnormal might or might not be also attributed to the inclement state of the weather, and perhaps also to the long journey in the steamer before they reached the hospital. This might also apply to the cold extremities.

After being put into bed, and the means described above used, the patients became bathed in a warm perspiration. In two cases the transition from coma to consciousness was accompanied by delirium. This in one case was so violent as to necessitate the use of a strait-jacket. After the full return of consciousness the patients felt very weak and much prostrated. [redacted] case (the longest unconscious) there was [redacted]che and giddiness on any

mental exertion five days after the accident. In no case was there any secondary complication. The shortest time of return to consciousness in the hospital was twelve hours after the accident, and the longest about forty hours. The patients say they do not remember any peculiar feeling at the time of the accident, except one, who says he felt as though he were being suffocated by sulphur fumes. To sum up, it may be stated that all had the appearance of narcotic poisoning, and that the lines of treatment used were based on the management of such cases.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Congenital Malformation of Heart.—Undeveloped Sexual Organs and Congenital Defect of Tonsils. Pulsating Tumour of the Head, with Raynaud's Disease.—Renal Lithotomy.

THE first meeting of the session of this Society was held on the 8th inst., Mr. Thomas Bryant, F.R.C.S., President, in the chair. The new volume of the Transactions of the Society was laid on the table for inspection.

Dr. CHARLEWOOD TURNER read a case of Congenital Malformation of the Heart, with Systolic and Prediastolic Basic Bruits, and made observations on the causation of bruits preceding the cardiac sounds. The case related was that of a cyanotic boy, aged six, under observation for four years with the same symptoms. A systolic bruit was audible over the pulmonary valve, followed by a well-defined "prediastolic" bruit running up to an accentuated second sound, and accompanied by a slight thrill. The bruit was conducted down the sternum. In regard to this case, it was pointed out: 1. That the character of the "prediastolic" bruit, and the associated phenomena prove its endocardial origin, and that a basic valvular bruit of this character can only be due to regurgitation arrested by delayed closure of rigid valvular curtains. 2. That with a rigid and defective but not incompetent valve there must be some reflex, which would, if of sufficient duration, produce a bruit with all the features of that heard, and the occurrence of such cases shows that the interval of the diastolic period preceding the second sound may be sufficiently prolonged for the production of a distinct bruit, while their rarity shows that this interval is appreciable under exceptional conditions only, as with a high degree of stenosis of the pulmonary orifice and hypertrophy of the right ventricle in the present instance. In regard to the bearing of such cases on the question of the causation of the "presystolic" bruit, it was pointed out: 1. That with a rigid and defectively acting, but not incompetent, mitral valve also, there must be reflux in the interval of the systolic period preceding the closure of the valve and first sound, which would, if of sufficient duration, produce a bruit with the distinctive features of the presystolic bruit, in these being referable to predominance of vibrations in the freely hanging curtains of the patent valve over fluid vibrations in the production of the bruit. 2. That the conditions are much more favourable to the production of a "presystolic" than of a "prediastolic" bruit by reflux: *(a)* The general expulsive ventricular systole which commences from a state of relaxation being slower than the impulsive action of the elastic resilience of the distended vessels; and *(b)* its commencement at the apex of the ventricle being separated by an interval from the first acts of the contraction of the cavity by the muscular fibres encircling the mitral orifice: this basal contraction, closing up and drawing aside the interpapillary space and propelling the blood into the apex and infundibulum, being preparatory to the general systole by which the blood is grasped and expelled, and seeming to represent the passage of vermicular contraction along the first limb of the vascular loop of which the heart is a development. Thus the occurrence of a "prediastolic" basic valvular bruit implies the more frequent occurrence of "presystolic" mitral bruits similarly produced. This fact seems thus to fully corroborate the views of the late Dr. Barclay as to the causation of this bruit, and at the same time to remove the basis on which the alternative auriculo-systolic hypothesis rests—the assumption, that is, that there can be no appreciable interval between the auriculo-ventricular impulse and the first sound. To this hypothesis it is directly objected that to refer a bruit running up with progressive intensification to an accentuated first sound supposes a forcible and impulsive ventricular contraction, of which there appears to be no evidence or probability, and is incompatible with the character of cardiographic tracings in such cases, which show a well-marked interval between the summit of the auriculo-systolic elevation and the ventricular systoles. Supposing these elevations to represent the force of influx into the ventricle, the tracings seem to be inconsistent with the hypothesis; but reasons are given for regarding them as indicative of the completion of the auricular systole—i.e., of the first act of ventricular contraction, and commencement of "presystolic" reflux where the valve is rigid. Reference is made to the occurrence of a "presystolic" bruit or modification of the first sound with that character in the absence of mitral stenosis, as another clinical observation according with Dr. Barclay's views, but not satisfactorily explicable on the alternative hypothesis. The conviction is expressed that Dr. Barclay's view of the causation of the "presystolic" bruit not only affords a sufficient explanation of the clinical facts, but the true interpretation of them.—Dr. CARRINGTON argued from a case of presystolic bruit, in which the left auricle had been filled with clot, that auricular contraction could not be the cause of the murmur.—Dr. COUPLAND said that the presystolic bruit was a definite one; it was of minor importance whether the bruit was due to blood flowing away from the ventricle or to blood flowing towards the ventricle. Clinically such distinctions were of little value.

Mr. A. PEARCE GOULD read a paper on a case of Undeveloped Sexual Organs, associated with Congenital Defect of the Tonsils. It was that of a male, aged twenty-seven, over 6 ft. high, slender, with fair, soft, smooth face, a boy's voice, and no hair on his face. The penis and both testicles were small, but the right epididymis was thickened, which Mr. Gould attributed to a blow on the part when the boy was eleven years of age. The prostate could scarcely be felt through the rectum, and the seminal vesicles could not be felt. The man had no sexual desire; the only sign of any sexual activity was occasional slight priapism. There was an oblique inguinal hernia on the right side. The pillars of the fauces were close together, and only very small tonsils could be seen or felt between them. Mr. Gould said the case raised the question whether there was any intimate connexion between the tonsils and the testicles. It was a popular notion that excision of the tonsils before puberty endangered virility, and Dr. Shorthouse, quoted by Dr. Ogle, was named as a writer who spoke of such an effect as a matter of common observation. The shrinking of enlarged tonsils, and the cessation of repeated attacks of tonsillitis at puberty, were adduced in support of the influence of sexual maturity upon these organs. On the other hand, in Zanzibar, where all boys have their tonsils excised, the testicles are well developed, and the operation now is so common that, were it liable to be followed by such a grave result as non-development of the sexual organs, abundant evidence of this fact would be forthcoming. The removal of an enlarged organ was different from its imperfect development, and might be attended with different results. Mr. Gould had seen two women with absent or undeveloped ovaries, and in whom the tonsils were of full size; and Dr. Langdon Down, who had seen many cases of imperfect sexual development, had not observed any associated change in the tonsils.—Mr. THOMAS BRYANT considered that there was no special relationship between the atrophy of the tonsil and testicle.—Dr. FELIX SEMON agreed with this opinion, and said that the size of the tonsil was very variable in the adult and appeared to have no relation to virility. There might well be a remote connexion between the tonsils and the testicles. Enlargements of adenoid tissue anywhere had a tendency to disappear after puberty. Authors had described cases of defective development of the tonsil associated with longitudinal slits in the anterior arches of the soft palate.—Mr. WARRINGTON HAWARD, speaking of the alleged connexion between the tonsil and testicle, said that in tonsillotomy removal of a portion of hypertrophied tonsil was all that was practised. What would happen to the testicle if the whole of the tonsil was removed could not be stated. In his opinion the man had as much tonsil as many virile individuals. That there was some connexion between the activity of the genital organs and of the tonsils he could not doubt; in many women the process of menstruation was attended with temporary swelling of the

tonsils.—Dr. HINGSTON FOX thought the atrophy of the tonsils and that of the testicles were mere coincidences. The diminution in size of the tonsils at puberty was but part of a general diminution of organs composed of adenoid tissue, and might be attributed to a lessened demand for leucocytes. At the period of menstruation there was general slight temporary congestion of lymphatic tissues.—Mr. RICKMAN J. GODLEE asked whether the patient had had mumps.—Mr. PEARCE GOULD could not say for certain whether the man had had mumps; the past orchitis was believed to be due to a blow from a cricket-ball.

Mr. F. TREVES read notes of a case of Pulsating Tumour of the Head, with Raynaud's Disease, and produced the patient for examination. The patient, a lad aged seventeen, complained of severe frontal headache, vomiting, and vertigo. These symptoms had existed for twelve months. Both carotids were considerably enlarged, as were also the temporo-facial and internal jugular veins. Over the arteries a loud and harsh bruit was to be heard, and a thrill felt. There was no arterio-venous communication. Certain vessels of the scalp were dilated. The right side of the face was a little larger than the left, the right facial muscles also acted with greater vigour. The right side of the tongue was larger than the left. The right eye was more prominent than the left, and the right palpebral fissure was the larger. There were nystagmus and occasional diplopia. The left external rectus was weak. The patient was liable to "hot sweats." Over the left mastoid region was a cirsoid aneurysm of peculiar character. It was the seat of an intense bruit. The skull beneath the tumour was marked by a number of irregular channels. There was a second pulsating tumour over the occiput. It was venous, and communicated through a fissure on the skull with the superior longitudinal sinus. It was the seat of a certain pulsation, but presented neither thrill nor bruit. The tumour was readily reduced. The sphygmographic tracings of the two swellings revealed remarkable differences. In the venous tumour the respiratory curve was evident. The pulsation in this tumour was derived from the brain. The skull presented certain irregular gaps and fissures, which appear to have been caused by veins in a state of congenital dilatation.—Dr. HALE WHITE thought that an explanation of the case founded on the idea that the sympathetic system was at fault was but ill-founded. Exophthalmic goitre should be remembered in connexion with the case. As to Raynaud's disease, he could not but think that the terms defective circulation and venous congestion would explain the appearances. Mr. TREVES, in reply, said that he had not attempted to explain the whole case, but only the origin of the venous tumour. Whatever the boy's state was, it was certainly not one of venous congestion.

Mr. BUTLIN read some further notes of a case of Renal Lithotomy published in the Transactions of the Society, vol. xv., p. 113, 1882. In a letter received on Feb. 3rd from the patient's father (a medical man), he says: "About a fortnight ago he had a good deal of pain in the left loin, very much as he used to have in the right. I found he was passing small pieces of calculus soft and friable, and that the urine was alkaline. I kept him quiet for a few days and gave him nitro-hydrochloric acid. The wound is now entirely healed, the urine normal except a little mucus occasionally, the pain in the loin quite gone, and I am happy to say he is progressing most satisfactorily. In December, 1882, I had received a note from the patient himself to say that at the end of the year he was quite sound and in excellent health." Again on Sept. 15th of the present year he had received information that the patient was quite well, and enjoying himself in South Africa. It had, he said, been proposed that in cases similar to this one the entire kidney should be removed. If this had been done in the present instance, not only would the risk have been materially increased, but when the other kidney was attacked the danger would have been very great.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Oct. 6th, Dr. J. B. Potter, President, in the chair.

THE following specimens were shown:—Dr. Malins: A Dermoid Ovarian Cyst. Dr. Lewers: (*a*) Microscopical Sections of a Uterus affected by Malignant Disease; (*b*) a Fœtus from a Ruptured Tubal Cyst, successfully removed through Douglas's pouch. Dr. J. Phillips showed an Ovum expelled thirty-four days after conception. Dr. R. Boxall exhibited the Thoracic Viscera of a woman who died in childbed with symptoms of pulmonary thrombosis due to dislocation of the heart into the left pleural cavity. Dr. W. Duncan and Mr. W. B. Sutton showed the Ovaries and Tubes from a case in which there was a hæmatocele due to rupture of the left ovary; also a pair of Ovaries removed for the cure of dysmenorrhœa.

Ruptured Uterus.—Dr. J. G. SWAYNE gave a description of four cases of ruptured uterus occurring in his practice—two complete and two incomplete. The first occurred about the middle of utero-gestation, and was not clearly traceable to any accident. The uterus appeared to have given way during the effort to expel a putrid five months' fœtus. The woman died undelivered, and a laceration was found in the anterior wall of the uterus, through which the child had passed, so that it lay between the uterus and bladder in a pouch formed by the peritoneum reflected from one to the other. In the second case labour had been induced at eight months, and the rupture had apparently arisen from a transverse presentation and the spontaneous expulsion of the fœtus, in a doubled state. In neither of these cases was the peritoneum torn. The third case was one of complete laceration, and the accident took place during the course of an ordinary labour at full term in a woman with slight pelvic deformity. She was delivered by craniotomy, but died on the fifth day after delivery. The fourth case was one of complete rupture, and occurred in a multipara during an ordinary labour. The child, which had partly escaped into the abdomen, was delivered by turning. Laparotomy was performed, the abdomen was thoroughly cleansed, and the wound in the uterus united by several sutures. Death took place within an hour afterwards.

Case of Rupture of the Uterus.—Dr. RICHARD COX gave the details of the following case. A multipara, aged thirty-eight, was taken in labour at 8 A.M. on May 2nd, and was attended by a midwife. Until 3 P.M. everything had appeared normal. The patient then suddenly screamed out, and became faint and sick. The expulsive pains ceased, but an agonising pain in the abdomen was complained of. Dr. Cox was sent for, and, being from home, arrived about 6.30 P.M. The patient was then moribund. After administering some stimulant, Dr. Cox passed his hand into the uterus, which was empty, and finding a rent of five inches in the anterior wall, he was able to seize a leg and bring the child back from the abdomen, together with the placenta, and to deliver them pretty quickly. There was some difficulty with the head, which was arrested at the brim by a slight contraction. The patient died shortly afterwards. She had had natural confinements previously.—Dr. BRAXTON HICKS said that so many points presented themselves that it was difficult to select, but he thought, when delivery had been effected and the uterus was found paralysed, when the rent was so large that a prolapse of the intestines occurred through the rent, that in such a case the best plan was to perform Porro's operation rather than to leave the case to its almost inevitable fate.—Dr. HORNOCKS thought operations per vaginam difficult, if not impossible, to carry out, and that abdominal section seemed the only method offering any hope. The question between carefully stitching up the rent or removing the uterus should be decided after carefully examining the site and size of the rupture, and more particularly the condition of the torn parts. If the laceration were severe, as usually was the case, Porro's operation would be best. If the edges were clean cut, they might be carefully brought together by sutures.—Dr. ROUTH said that, while agreeing with Dr. Braxton Hicks, there was another rule not one whit less important. When the case was ascertained to be one of rupture of the uterus, it was an unnecessary piece of cruelty and malpraxis to attempt to extract the child per vaginam, irritating the bowels with your hand, and running the risk of enlarging the tear in the uterus or increasing hæmorrhage and shock. The rule should be to proceed at once to abdominal section. Whether in cases of the tear being very ragged Porro's operation were preferable to sewing up the uterus might admit of question, but in any case the child should be extracted without delay by abdominal section, and not per vaginam.—Dr. GALABIN thought that, notwithstanding the improvements in modern surgery, rupture of the uterus, involving the peritoneum, would always be a very fatal accident. He had no doubt [illegible] where the child had escaped

through the rent, and the patient's condition permitted any interference, the operation should be abdominal section, and not removal of the child through the vagina. The empty and partially contracted uterus would occupy more of the pelvic diameter than when stretched over the fœtus, and extraction through the pelvis might be difficult, and increase the injury to the soft parts. He thought Porro's operation would be rarely advisable, as in all the cases he had met with the rent had commenced in the vagina or lower segment of the uterus, and in such cases it would be impossible to remove the whole rent by Porro's operation. When the rent was higher and ragged, this operation might be preferable.—Dr. CHAMPNEYS thought everyone must agree with Dr. Routh, that after the diagnosis of rupture of the uterus and escape of the fœtus is once made, no attempt should be made to extract the fœtus *per vias naturales*, nor should any second person examine per vaginam. He thought that Porro's operation (taking advantage as it did of all the latest antiseptic improvements) had been compared with the old-fashioned non-aseptic Cæsarean section, and to the advantage of Porro's operation. The recent improvements in the Cæsarian operation by Sänger, who uses numerous deep silver sutures and superficial silk ones, so as to leave no communication between the uterus and peritoneum, had shown that the comparison was fictitious. He doubted if Porro's operation should in any case be preferred, as part of the rent is so frequently below the line of amputation, not to mention the additional injury caused by it.

Papilloma of the Fallopian Tube and the relation of Hydroperitoneum to Tubal Disease.—Mr. ALBAN DORAN read a paper on this subject. Papilloma of the Fallopian tube is, he said, a rare disease, but may exist and produce marked symptoms. The papillary growth may represent not so much a true tumour as a product of inflammation. It is at least not malignant. In this disease a pelvic tumour, which may extend into the hypogastrium, always exists. Pain does not appear to be essential, and when present is possibly due to other disorders. Two cases, both under the author's observation, were described. In one case the affected tube was closed, the symptoms were entirely pelvic, and no hydroperitoneum was present. This case showed that papilloma of the tube may simulate hydrosalpinx. In the other case the ostium of the tube remained patent, and hydroperitoneum persisted till the diseased tube was removed. There was positive evidence that secretion escaped from the ostium. For reasons given at length in the paper, the latter case suggested that the disease described as hydroperitoneum, and understood to signify effusion into the cavity of the peritoneum due to disease of that serous membrane alone, may frequently, though not invariably, be due to mild chronic catarrh of an unobstructed Fallopian tube. The discussion of this paper was deferred till the next meeting of the Society.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

THE first meeting of the session was held on October 8th, the President, Dr. C. S. Smith, in the chair.

The PRESIDENT, in his opening remarks, alluded to the recent lamented death of Dr. Chadwick, who had taken great interest in the formation of the Society, and was its first president. He congratulated the members on the present flourishing condition of the Society, which he attributed to the fact that they eschewed ethical questions, and that their discussions included the theory no less than the practice of medicine.

Reunion of Tendons. Mr. JESSOP showed three patients, in whom divided digital tendons had been reunited by suture. In two cases the flexor, in one an extensor, tendon was affected. He remarked that the distal end of the tendon was in each case found at some distance from the wound, and required some force to bring it into position. The result in each instance was very good.

Trephining for Paralysis.—Mr. ROBSON showed a patient whom he had trephined over the left brachial centre for paralysis of the right arm, caused by a blow on the head a week previously. A small spicule of bone was removed. The operation was followed by complete recovery of movements of the arm.

Simultaneous Distal Ligature of the Right Carotid and Subclavian Arteries for [illegible] Innominate Artery.—Mr. HARTLEY showed a case in which he had performed this operation. The operation was performed on Sept. 1st, 1885, the patient being then almost *in extremis* from the pressure of the tumour on the larynx and œsophagus. She slowly recovered, and still remains in very fair health, but there is now a return of pulsation in the innominate region.—Mr. WHEELHOUSE suggested the employment of galvano-puncture.—Dr. CHURTON mentioned a case in which the patient died twenty minutes after galvano-puncture, due to the rupture of another part of the sac. The part operated on contained only a soft gelatinous clot, which he thought would prove rather a source of danger than relief.—Dr. BARRS thought galvano-puncture ought to be tried. He mentioned two cases in which benefit had been derived from it.—Mr. WARD mentioned three cases under the care of Mr. Jessop of distal ligature of the subclavian and carotid. In the first silk ligatures were used, and death ensued from secondary hæmorrhage on the forty-ninth day. In the second catgut ligatures were used, but the aneurysm was not cured and the patient was lost sight of. In the third silk ligatures were employed and secondary hæmorrhage occurred, which was stopped for two days by a ligature applied to the carotid, and, on a recurrence of the hæmorrhage, by galvano-puncture. He remarked on the advisability of using catgut ligatures.—Mr. MCGILL suggested the ligature of the vertebral artery.

Laparotomy. Mr. LAWFORD KNAGGS read notes of two cases in which laparotomy had been performed for chronic obstruction of the small intestine. In both tubercular disease was found to be the cause by matting the intestines together. One case proved fatal; the other recovered from the obstruction, though the operation consisted only of an exploratory incision. He remarked on the satisfactory result in the second case, and discussed the possibility of the incision having exercised a good effect on the disease. He thought that a large proportion of cases of chronic obstruction of the small intestine might be relieved by operation, and that in all cases not obviously hopeless exploration should be undertaken. To the three methods hitherto adopted—viz., enterotomy, division of adhesions, and resection—he would add a fourth—viz., the union of the intestine above the obstruction to that below, in the same manner as had been adopted in the excision of the pylorus for cancer.—Mr. PRIDGIN TEALE mentioned a case where laparotomy was performed and cancer of the sigmoid flexure found, but, curiously, before colotomy could be performed, the patient's bowels were freely moved.—Mr. MAYO ROBSON said he had found, in two cases where he had opened the abdomen in tubercular disease, great relief ensuing to the general symptoms after the operation.

Case of Chronic Anterior Poliomyelitis and Paralysis of all kinds. Dr. CHURTON showed this patient, a woman aged twenty-six, who, after being paralysed for several months, had regained muscular movement and strength. The progressive atrophy began after her delivery of twins in January, 1881; the paralysis of limbs was almost complete in August, 1885. Sensation was perfect. Faradaism and tonics seemed useless; potassium iodide did harm. A hopeful prognosis was given, of course with reserve. She was subsequently well cared for in a healthy house in the country, but used neither drugs nor galvanism. In August, 1886, she could walk fairly well, now almost perfectly, and the deltoids and other muscles were now also normal. Dr. Churton thought this a striking example of the tendency of tissues originally tolerably sound, but damaged by temporary causes, to reassert themselves under favourable conditions.

MEDICAL INSPECTION IN BROOKLYN.—The Brooklyn Commissioner of Health, Dr. Andrew Otterson, has inaugurated in that city a system of medical inspection and relief in the tenement-house districts, with special reference to the diseases of infants during the heated season. Ten physicians have been appointed, each assigned to a special locality, who are instructed to search for sick children needing attention, and to care for them, furnishing medicine gratuitously where parents are unable to pay for it, and at a reduced price to those who can.

THE LATE DR. WELLS, OF READING.—The Town Council of Reading has approved a proposal to promote a memorial to the late Dr. Wells. Part of the amount to be raised is to be devoted to the providing of prizes for the students at the Reading Schools of Science and Art.

Reviews and Notices of Books

A Manual of Diseases of the Nervous System. By W. R. GOWERS, M.D., F.R.C.P. Vol. I. London: J. and A. Churchill. 1886.

IN the space at our disposal it is impossible to do justice to works like the one that lies before us. We must therefore confine ourselves to indicating the scope, matter, and manner of Dr. Gowers' book. This is the first volume of the manual, and deals with the diseases of the spinal cord and nerves. The student and practitioner will find in it a true friend, guide, and helper in his studies of the diseases of these parts of the nervous system. It is a most complete manual, presenting a thorough reflex of the present state of knowledge of the diseases of the spinal cord and nerves. The care and thought that have been bestowed on its production are evident on every page. In the presence of such ability, learning, and originality, criticism can only take a favourable direction. The style and manner are accurate, studied, and adequate never diffuse. The illustrations call for special notice. They are numerous, new, and original. The author has largely pressed into his service the phototype processes of the Typographic Etching Company, and with good results. Some of the figures are truly excellent. The definition of Figs. 71, 82, 86, 88, 89, and 91 will bear witness to the truth of this assertion. The arrangement of the matter is simple and easy of reference.

Part I. opens with a consideration of the general symptomatology, including a description of the method of investigating symptoms. The chapter on the action and paralysis of muscles will prove of special value to the student when in the presence of cases of paralysis of individual muscles. Part II. treats of the diseases of the nerves, gives a careful account of nerve injury and degeneration, including therein the various changes in the electrical reactions of the nerves and muscles. The articles on multiple neuritis are some of the best in the book. Part III. commences with a complete account of the medical anatomy of the cord; it contains a diagram and description of "an element" of the motor path. This idea commands attention. An element of the motor path may be regarded, according to Dr. Gowers, as consisting of two similar segments, the upper and the lower. The upper segment consists of a large pyramidal cell, which communicates with the large spinal motor cell by means of a terminal ramification of nerve fibres, which is likened by the author to the terminal ramification at the distal end of the lower motor segment. We do not remember to have anywhere seen so clear a description of the mode of junction of the cerebral motor with the spino-muscular motor segment. In another part of the book Dr. Gowers points out that the nutrition and function of the terminal ramification of both motor segments are likely to be readily interfered with owing to the long distance of these termini from the source of trophic influence, which the author regards as the motor nerve cell itself; for the belief in the separate existence of trophic centres he sees no warrant. Curare paralyses the termination of the lower motor segment. It is asked whether there are not drugs and other causes which may annihilate the function of the terminus of the upper segment. This upper terminus is regarded as possibly of the nature of a local inhibitory centre, loss of the function of which would lead to "permitted hyperphysiological activity" of the spinal motor centres. The pathology of functional or hysterical paraplegia may be explained in accordance with these views. Suppose from any cause the motor centres of the cerebral cortex have their nutrition lowered, this lowering would tell most and first on the terminal ramification of the pyramidal fibres in the cord, and naturally on those fibres which had the longest course in the cord, consequently those of the leg. Taking this idea into consideration with what has been said anent local inhibitory centres, it will be seen how "functional" or "nutritive" spastic paraplegia may be accounted for.

In forty pages devoted to locomotor ataxy we think the student and practitioner will find, considering the small amount of space occupied, the most harmonious and full account of the disease in the English, German, or French language. The chapters on the varieties of muscular atrophy will be welcomed by all students, as conveying in a concise form all that is at present known of this complicated subject, whilst the discussion of the various forms of degeneration of the spinal cord is equally complete. The student and practitioner will be thankful also for the attention that the author has given to the treatment of diseases of the cord and nerves. Dr. Gowers has a good word in many places for massage, electricity, and other methods in vogue in the treatment especially of nervous diseases, but he also denounces the use of such remedies in other places, or at least asserts that in his experience in certain kinds of disease he has seen no good result to follow even carefully carried out courses of massage, &c.

Space exigencies forbid, or we should have liked to point out further excellences in Dr. Gowers' work. Whether we contemplate the erudition, meditate on the suggestiveness of the original matter, admire the illustrations, or think of the care that has been bestowed in apportioning the space to each subject according to its importance—from whatever point of view we regard this book, we must express the opinion that, judged by its first volume, no better manual on nervous diseases has been presented to the medical profession.

OUR LIBRARY TABLE.

Manual of Differential Medical Diagnosis. By CONDICT W. CUTLER, M.S., M.D. New York and London: G. P. Putnam's Sons. 1886.—Whilst admitting the general utility of such handy books of reference as the above, where in tabular form the reader finds presented the main features of difference between diseases that bear a superficial resemblance, yet we are sceptical as to their real educational value. To the student the advice should be to grasp the differences in clinical features by his own observation, and rather construct his own tables than rely on those already prepared for him by others. In saying this, we by no means desire to find fault with the way in which Dr. Cutler has planned and compiled his little book. We have given it a tolerably careful examination, and are pleased to find it accurate and intelligible. It is true, it would not be difficult to find fault with him for laying stress upon symptoms which are inconstant, or, at any rate, of such minor importance as to be of little service in differential diagnosis; but in the main he has succeeded in his endeavours to present to the student and practitioner a digest of symptomatology. The student must, however, guard against the mistake of allowing, for examination purposes, the information so choicely selected for him to replace the knowledge he personally would gain by diligent work in the wards.

Manual of Hygiene for Schools and Colleges. Prepared by the Provincial Board of Health. Pp. 293. Toronto: W. Briggs, 1886. This book has been published under the authority of the Minister of Education in Canada "for use in all the schools under the control of the Education Department." It is intended to supply a want which has long been felt "of a work on hygiene, which would occupy an intermediate place between the elementary text-books for the use of children and the advanced treatises for practitioners of medicine, sanitary engineers, and other persons intending to become expert [redacted] science." It appears to be

remarkably well adapted for the purpose for which it was prepared, and has evidently been drawn up by men well acquainted with the literature of the subject, and also possessing a thorough practical knowledge. A considerable amount of attention has been given to the subject of school hygiene, both as regards the furniture and fittings of the class-rooms, and the management of the pupils during the hours of study and recreation. The various influences likely to affect injuriously the vision of the children in schools are carefully discussed, and the subject of over-pressure has received a considerable amount of attention, and appears to be treated with sound judgment. The concluding chapter of the book contains the information usually given in the manuals on first aid to the wounded. As a whole, it is an excellent manual for the instruction of teachers in the important principles of sanitation, and in the measures necessary for the preservation of public health; and it has the advantage of a very copious index. It does the greatest credit to the Education Department of the Dominion of Canada, and to the members of the profession by whom it has been drawn up. A similar work for the use of our training schools, under the sanction of the Education Department, would be a valuable addition to our school literature.

Dr. Paul Boerner's Reichs Medicinal-Kalender, 1887. Herausgegeben von Dr. S. GUTTMANN. Theil I.: Geschäftliches Taschenbuch und Beiheft. Leipzig: G. Thieme. 1886.—The late Dr. Boerner in establishing this calendar did good service to his brother practitioners, and the favour with which it is received shows how that service was appreciated. The first part of the work consists in a substantial pocket-diary and almanac, with which is incorporated a vast amount of information—such as a table of the German Pharmacopœia and remedies outside its limits, with dosage and therapeutics, the table being compiled by Dr. Oscar Liebreich; lists of baths and mineral springs; hints for "first aid" in cases of sudden illness; symptoms and treatment of acute poisoning; a condensed list of diseases, &c. In the supplement we find sections on clinical thermometry and urinary analysis by Professor Jürgensen; on ophthalmological practice, with test-types, by Dr. Horstmann; otological, by Dr. Jacobson; and odontological, by Professor Miller. Anthropometrical tables, schemata for post-mortem examinations, and full directions for the bacteriological examination of sputum and intestinal evacuations, with illustrations of the comma bacillus, are also features of this little work, which comprises further sections upon the most important methods of hygienic research. It is a veritable *multum in parvo*, and we are not surprised at its popularity in the Fatherland.

Transactions of the College of Physicians of Philadelphia. Third series. Vol. VIII. Philadelphia: P. Blakiston, Son, and Co. 1886.—This handsomely printed volume contains many papers of considerable interest. Dr. H. C. Wood makes some remarks upon "Chronic Contracted Kidney with Normal Urine," in which he throws out the somewhat novel suggestion that in suspected cases a therapeutic test might be employed in the shape of cantharides or turpentine. "If on trial it should be found that a slight irritation would seriously affect the urine, the case should be looked upon with the greatest suspicion." Dr. A. V. Meigs reports on a "Case of Occlusion of the Vena Cava Superior," where a dissection displayed the course of collateral circulation by the internal mammary, intercostal, and azygos veins. Some cases of general anasarca and acute pulmonary œdema form the basis of a paper by Dr. E. T. Bruen on "Disturbance of the Normal Vaso-motor Tonus." Dr. Da Costa writes on the Hypodermic Use of Hydrochlorate of Cocaine (dose one-third to half a grain), in which mode its analgesic effect is, he states, not [illegible] distinctly as a cardiac stimulant. Dr. P. J. Mays gives the results of his inquiry into the Analgesic Effects of Theine, which he found to contrast with cocaine, but to be very efficacious. The same writer has an interesting experimental inquiry "On the Nutritive Value of Some Beef Extracts." Dr. H. Leffmann argues in favour of the prescription of pure alcohol in preference to ordinary fermented liquors. Amongst other papers worthy of notice are—"The Mechanism of Indirect Fractures of the Skull," by Dr. Dulles, copiously illustrated; "On the Anatomical Bearings of the Serous Covering of the Viscera," by Dr. Oscar Allis; "On Sunstroke and Heat Exhaustion," by Dr. Orville Horwitz; "On Photography of the Larynx," by Dr. T. R. French; "On the Basal Pathology of Chorea," by Dr. H. C. Wood; "On Raynaud's Disease," by Dr. J. H. Musser; and "On Constipation," by Dr. A. V. Meigs. The volume opens with obituary memoirs of Drs. John Light Atlee and George Hamilton, followed by an address by the retiring president, Dr. J. M. Da Costa.

Malarial Fever, as met with on the Gold Coast.—By C. H. EYLES. Printed for the Government of the Gold Coast Colony. London: Waterlow and Sons. 1886. This is an interesting *brochure*, which bears evidence of considerable painstaking and scientific research on the part of its author. It is less of the nature of a clinical than of a pathological treatise, and is particularly valuable for the study it gives of the subjects of icterus and hæmoglobinuria in relation to remittent fevers. The writer's standpoint may be gathered from the following passage, in which he explains his subdivision of the phenomena of malarial fever into the essential and the secondary. "Under the essential I place the purely febrile phenomena i.e., those met with in fevers generally viz., elevation of temperature, with gastro-intestinal, circulatory, cerebral, urinary, and other disturbances, the distinguishing feature being that the fever is paroxysmal and periodic; so that in cases of remittent (single paroxysm) there will be diurnal variations of temperature, not necessarily at the times in which they occur in continued fevers, but determined by the time of onset of the paroxysm. And among the secondary phenomena I place those symptoms traceable to solution of hæmoglobin—viz., icterus and jaundice, hepatic and splenic complication, and hæmoglobinuria." He reprobates the introduction of the term "blackwater fever" to indicate the severe form of remittent, preferring the older term "bilious remittent." Sections are devoted to the etiology of malaria, and to treatment, which latter contains some useful hints as to the administration of quinine.

Hospital Reports: Middlesex Hospital.—This hospital is one of the few that publishes a fairly full report of the cases that have been under its care each year. The volume before us is for the year 1884, and contains the reports of the medical and surgical registrars, and also an account of the work done in the post-mortem theatre. For these reports the following gentlemen are respectively responsible: Dr. Pringle, Mr. Roger Williams, and Dr. Kingston Fowler. We have only the space to say in general terms that the volume is one that no registrar should be without, and one which any compiler of statistics would find replete with information of a certain order. There are special tables on enteric fever and malignant growths. The table of necropsies is very instructive.

Transactions of the American Ophthalmological Society: Twenty-first Annual Meeting. New London, Conn. 1885. Boston: Published by the Society. 1885.—In this part are several interesting papers. Dr. Bull records a case of abscess of both frontal sinuses. In this case an opening was made into the sinus, much fetid pus removed, and recovery resulted. Knapp recommends the use of the actual cautery in destructive corneal processes. Dr. Fryer gives a case of bony cystoid tumour of the orbit caused by and enclosing

a piece of wood. Dr. Mathewson reports a case of epithelioma of the eyelid cured by applications of benzoic and calomel. Dr. Dennett supplies a new form of test-type founded on correct principles, and Dr. Hasket Derby does good service in reporting two cases of penetration of the eyeball by scissors during the operation for strabismus. In these cases recovery took place, but if carelessly treated there would be much probability of loss of vision or of the eye, with a risk of sympathetic ophthalmia.

Studies from the Biological Laboratory of the Johns Hopkins University, Baltimore. Edited by H. NEWELL MARTIN and W. R. BROOKS. Vol. III., No. 5.—The present number is devoted to Embryology and Microscopy. Dr. H. Leslie Osborn gives a minute account of the development of the gill in Fasciolaria, accompanying the memoir with a plate in which the successive stages are clearly shown; and Dr. H. G. Beyer communicates a paper on the structure of Lingula (Glottidia) pyramidata, with four plates of illustrations.

Spasm in Chronic Nerve Disease. By SEYMOUR SHARKEY, M.B., F.R.C.P. London: J. and A. Churchill. 1886.—This book is a reprint of the Gulstonian Lectures, delivered by its author at the Royal College of Physicians of London in the spring of the year. We have already had occasion to speak in terms of much appreciation of these lectures. We need now only say that the profession will doubtless be thankful to the author for supplying them with his valuable facts and inferences on spasm in chronic nerve disease in a separate and easily procurable form.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[SECOND NOTICE.]

IN our former notice of this Cholera Report we referred to the attitude of the British delegates at the Rome Conference in resisting the imposition of a five days' quarantine on ships which an internationally appointed medical officer might choose to regard as infected, in the place of trusting to the system of sanitary administration which has been carried out in this country, where an average annual expenditure of some £8,000,000 is voluntarily sustained for this purpose. This attitude, which was consistently maintained by all the delegates from this country, evidently led to the break-up of the Conference, for, as Dr. Buchanan points out, after an adjournment it never met again. But it must not be thought that the labours of the Conference have been inconclusive. Referring again to Dr. Thorne Thorne's account of the proceedings of the Conference, we find that at the date when the delegates were originally intended to reassemble, the Italian Government, which in the meantime had had opportunity of considering the attitude of the majority of the Technical Commission, including their own delegates, in this matter, issued a *Mémoire*, which cannot fail, in the long run, to have an important influence on any future international gathering called together to deal with this subject. Summarising this *Mémoire*, Dr. Buchanan explains that it indicated that an international understanding on the sanitary *régime* of the Red Sea and the Suez Canal had become imperative; that the existing professions of control over isolation and disinfection were utterly vain for any sanitary purpose; that reforms of practice in the Red Sea and the Canal were imperative; and that it went on to declare that the adoption of the reforms indicated would allow of such free use being made of the canal as a highway, as England had contended for at the Conference, permitting the abolition of existing restrictions upon the movements of vessels, not only in the case of English shipping, but in the case of vessels of all nations. Such a document, emanating from the Government of the country which called the Conference together, must be regarded as of high value; and we, at least, are satisfied to find that it entirely endorses the contentions of our delegates.

In Dr. Thorne's account of the distribution of cholera in Europe, in 1884-86 we find that for each year there is a statement of the importations of the disease into this country. These importations were few in number, but none of them led to any extension of the disease. As to this the annual report makes no boast, but it with reason implies that English sanitary administration may claim some credit for the result, and it proceeds to detail the action taken in this country in view of the European epidemic. Under Dr. Buchanan's supervision, and with the aid of Dr. Ballard as a senior inspector of long experience, a staff of medical inspectors was employed in 1884 and 1885 in visiting the port, riparian, and inland sanitary districts; those districts being specially selected for inspection where the Local Government Board knew, from previous reports and visits, that conditions of soil, water, or air pollution had existed which indicated a state of unpreparedness to resist the infection of cholera. These inspections were followed by interviews with the sanitary authorities of the districts in question, who were urged to remedy such conditions as called for remedy and to provide themselves with means for isolating first cases of disease. The total action taken in this way is shown by means of special reports by Dr. Ballard on the survey generally, and by Dr. Blaxall, R.N., on the principal port and riparian districts, and the whole is summarised in a more or less tabular document covering over two hundred pages. At first sight such a report appears eminently uninteresting; but, for all this, it is perhaps that portion of Dr. Buchanan's report of which this country may well be most grateful and most proud. Where responsibility for sanitary duty was found to be wanting, the inspections, we are informed, often "conduced in valuable measure towards its development"; and where local authorities were desirous of performing their sanitary duties towards their own districts and the kingdom generally, they were "greatly aided by the inspectors' visits, and have been correspondingly grateful to the Board for the advantage thereby afforded them." Such work as this, extending as it has done all over the country, must materially have advanced the interests of the community in the matter of health, and we can well believe Dr. Buchanan when he states that the duty of caring for the public health is by such measures becoming "increasingly apprehended by English communities." So also the action taken by means of this survey goes far to show to European and other nations that the opposition shown at the Conference to quarantine *versus* sanitary administration was not based on any considerations of commercial interests or economy. Although this country has for years past devoted large sums of money to the improvement of public health, the moment a European danger appeared additional expense was incurred by the central authority on the advice of their Medical Officer, and increase of expenditure and of vigilance was pressed upon local authorities. By such means the country not only arms itself in the best known way against invasions of cholera, but, at the same time, it succeeds in reducing the amount of its sickness and death from all causes. But this tabular report has further advantages. It contains at one glance an indication of the sanitary state of a vast number of our sanitary districts. Thus, if a visit to the seaside is contemplated, and doubt exists as to whether Dover or Shoreham should be selected, the reader may turn to the volume and find that at Dover the town is sewered throughout, the ventilation and flushing being satisfactory; that the waterclosets system is satisfactorily arranged; that refuse-removal is satisfactory; that the water-supply is one on the constant service system; that the work of the medical officer of health and inspector of nuisances is satisfactory; and that as regards other matters, progress is steadily arrived at. Turning next to New Shoreham, he will learn that the sewers are insufficiently ventilated, whilst private drainage is defective and a source of nuisance; that the waterclosets are mostly without flushing arrangements, and, as such, are a nuisance; that refuse-removal is not altogether satisfactory; that though the town has a public water service, local wells are liable to surface contamination, and that some houses have no supply; that though the work of the medical officer of health is "fair," that of the inspector of nuisances is unsatisfactory, and that sanitary administration is "lax." Had this report been issued earlier, perhaps some who suffered during the recent epidemic of typhoid fever in Shoreham might have escaped. Anyhow, this volume should be in the hands of every medical practitioner who has to advise his patients as to which localities they may visit with benefit, or which they should studiously [redacted] public also may well consult it in the same

THE LANCET.

LONDON: SATURDAY, OCTOBER 16, 1886.

THE Introductories have been duly delivered, and if half the good thoughts and good advice they contain are taken to heart by the students there will in a few years be a great gain to the profession. We believe, after all, in a good Introductory. The voyage on which a medical student enters in October, and which is to last for three or four years, is beset with dangers as well as duties. It may be made very pleasant or infinitely painful, and the burden of all the Introductories is the same. They aim at inspiring the love of truth, and encouraging its pursuit at all hazards. The history of discovery, or of individual men, whose fame has added lustre to their particular school, is in turn used by the lecturer, and used with such success that the student must blame himself if he enters on his great career with low aspirations and poor motives. We should advise each student to read all the addresses. There is much variety of conception and execution in them, and they will amply repay the time and trouble spent in their perusal. The thoughts of other teachers, and the history of other schools than his own, will save him from narrowness, and will supply him with arguments in variety for dutifulness and virtue. A very short experience will suffice to introduce a student in any school to men who affect to be wiser than their teachers, and who receive the loftiest thoughts with indifference or something worse. An Introductory Lecture to them is no gain. Nothing in it excites their admiration. They speak as if they had lived longer and seen more than their teachers, and as if it were a favour in them to be present, even if their object be to distract and disturb those who come to listen and to profit. Such men are in a minority, and it is very desirable the minority should be a still smaller one. Let any well-meaning student study the Introductories, and regard with some suspicion those who disparage them. It is impossible, and it would be somewhat invidious, to single out individual lectures for praise or blame. It would be useful for each student to put down on a piece of paper the great points in the Address of each lecturer and bear them in mind during his whole course of study. The character of medical students is well vindicated by Dr. WADHAM, and also by Dr. BISS in his lecture at the Middlesex Hospital. Dr. BISS showed that at Cambridge during the last eight years, while the number of medical students has increased from fifty to over three hundred, there has been an immense gain to order, decency, and morality. Dr. WADHAM argued with much ability against the necessity for providing home discipline and accommodation for medical students. The argument showed the complicated nature of the question, and the difficulty of giving to any Collegiate authority in London the powers enjoyed by the Universities of Oxford and Cambridge. Sir BENJAMIN BRODIE's experience, that the ranks of medical students contain a large number of young men diligent in the pursuit of knowledge and de[illegible] general conduct, is very valuable, and w[illegible] true than it is to-day. But no wise student would underrate the value of a home in which home virtues can be cultivated, and something like home authority used to promote regularity of habits and steady application to work. St. Thomas's Hospital was fortunate in having Dr. BRISTOWE to tell its history, and to pronounce the existing arrangements and prospects of the hospital worthy of its past, and much better than they might have been when some of the errors of the past are considered. Dr. GEORGE JOHNSON spoke with authority against all narrow specialism in medicine, and was very happy and forcible in his illustrations. His prophecies of the doom of those who despise vaccination will not immediately affect the fanatics of Leicester; but they will be realised some day by many who laugh at them now. JENNER'S association with vaccination is trite, but his association with the violin is not so well known, and it was a happy idea of Mr. BLACK, in urging the cultivation of music by medical students, to remind his hearers of the solace that JENNER derived from playing the violin and the flute when the cares of his great discovery weighed heavily upon him. One of the most thoughtful Introductory Addresses of the session is that of Mr. MALCOLM MORRIS, at St. Mary's, on Mysticism, Materialism, and Scepticism in Medicine. We insert Mr. MORRIS'S address in full this week, and have only now to say that it is a masterly and yet reverent exposure of some of the worst faults of medicine, ancient and modern, the study of which will make us all more safe against error, and more helpful in raising the reputation of medicine. For much of the affected mysticism and dogmatism of the professors of medicine in the past, Mr. MORRIS blames the public who loved to have it so. But the public and the profession, too, are both strong enough now to dispense with all such aids to authority, and to respect those advisers most who show the greatest desire to introduce simplicity and truth into medical treatment. Mr. BARKER'S Address at University College indicated the claims of medicine to more recognition by the public, and to more honour from the State. He was especially happy in showing how medical men, as a rule, steer clear, beyond most men, between errors of superstition on the one hand and a degrading materialism on the other. No doubt medical men are "lightly esteemed" as yet by the State. They have no place in the House of Lords. So much the worse for the House of Lords. The House of Lords would be much stronger to-day against attack, and in the respect and affections of the people, if it contained the eminent men of all professions, and especially of our own. For the welfare of the State the advice and counsel of the best of all its citizens are needed, and in the Second Chamber of the near future we may hope such citizens will not be conspicuous by their absence. But, after all, the chief reward of medical men must be of a different character from any that the State can give. It must be the approval of men of science generally. The peers of medical discoverers must themselves be men of science, and this recognition of medicine has already begun, and cannot fail to grow as the discoveries of medicine multiply and appeal to the admiration and gratitude of mankind.

THERE are probably few more lucrative departments of the healing art than "bone-setting." Unfortunately for the

profession, and certainly also for the public, the procedure, as a "specialty," has been monopolised by, legally speaking, irregular operators. The cause of this is not far to seek: for, in the first place, the joints, with their complex anatomy, furnish a favourable field for the exhibition of the bone-setter's pretensions; and, in the second, they enable him still further to trade upon the credulity of his clients, since he is able at least to make some visible show of the means and mechanism adopted to effect the end indicated by his stereotyped assertion that this or that bone is out of its place.

Medical men might well view with complacency, and even with contempt, this counterfeit presentment of legitimate surgery, and the notoriety achieved by men who, whatever their dominant motive, are certainly none too scrupulous in making capital out of popular recognition, were it not for the fact that only too frequently the qualified practitioner is made the gauge whereby the alleged superior skill of his unlicensed competitor is measured. Nor does the unfairness of the comparison rest on popular grounds alone, for every now and then cases are met with in which our judicial authorities are found to weigh the credentials of surgeon and amateur on what, according to their lights, they consider a righteous balance, and find the former wanting. An instance of this we had occasion to comment upon in our last issue, where a County Court judge nonsuited a medical man, in the belief that he had failed to recognise the nature of an injury which a "bone-setter," who claimed hereditary talent in his calling had, as he said, diagnosed and summarily remedied. It has been truly said that the mind is more struck by positive than by negative evidence, and surely the subject matter of these remarks bears no exception to the general rule. As Sir JAMES PAGET has pointed out, those who consult bone-setters are sure to publish and laud his successes, whereas in the case of his failure they are too chagrined to parade themselves in public as the dupes and victims of mistaken confidence. Again, there is always a strong tendency to regard the works of intuitive handicraftsmen as veritable triumphs, whereas they are often enough merely the outcome of sheer operative audacity. "Adventures are to the Adventurers" applies as closely to the professed bone-setter as to "Ixion in Heaven." Where many chance shots are made some quarry will be killed, and equally where many stiffened joints are *wrenched* some will be loosened with advantage. And herein lies the talisman whereby the "bone-setter" commands a certain amount of success and reputation. Patients having dislocated tendons, displaced inter-articular fibro-cartilages, joint adhesions, and spastic contraction of muscles are not uncommonly benefited by movements, and that, too, perchance, by the application of rude, unwarrantable force. The following is a frequent sequence of events. A person receives a severe sprain of a joint—say the ankle. He submits for a time to the quiet ordered by his medical attendant. The inflammation subsides, but stiffness remains. Readily persuaded of the vaunted powers of a certain bone-setter the patient surreptitiously seeks the latter. His joint is handled with vigour, adhesions give way, and thus the medical man is deprived of the chance of completing a cure which it is certain he would not have neglected. But there is yet another side of the picture, and it is high time the public were made aware of its existence. If a bone-setter fails in his attempts, it must not be supposed that the failure is of mere negative moment, for it often implies that irreparable damage has been sustained through the application of force which no properly educated and qualified surgeon would have dreamt of using. Sir J. PAGET records a case where violent manipulation by a bone-setter was exercised upon a fractured limb. We ourselves know an instance in which a bone-setter, ignoring the diagnosis of an eminent surgeon, violently wrenched a shoulder for "stiffness," whereas the immobility was caused by a malignant tumour of the humerus. The natural result of such a procedure is not problematical. But, worse to relate, the patient, hesitating between the conflicting statements of the surgeon and the bone-setter, refused to have the limb amputated, and his life was sacrificed. The treatment of dislocations as practised by a legally qualified surgeon must not be confounded with the irregular operations of men whose knowledge of the subject, generally speaking, varies directly as the scruples of their consciences and inversely as the audacity of their actions.

THE treatment of various forms of the alcoholic habit by means of strychnine, which has been recommended from theoretical and clinical researches by LUTON, GIACOMINI, MAGNUS HUSS, MOREY, LECUYÉ, JAILLET, MINOZ, DUJARDIN-BEAUMETZ, and AMAGAT, has recently been tried by some Russian practitioners, and found to give gratifying results. Dr. POPOFF, writing in the *Vrach* (No. 10, 1886), after giving a *résumé* of the results obtained by the French and Italian observers above named, mentions some cases of dipsomania which he had successfully treated in the same way, and in the last number of the *Vrach* (No. 38) Dr. K. K. TOLVINSKI describes the case of a man, aged thirty-four, belonging to a neurotic family, very anæmic, but with no organic disease, who had drunk hard for many years, and with whom of late the outbreaks had been as frequent as two or three every month. He was treated with chloral, bromide of potassium, and opium, with but little success, his extreme distress, desire for drink, nausea, vomiting and unusual weakness being unaffected. On the last occasion, when he had been drinking for some days, Dr. TOLVINSKI decided to make trial of strychnine, and began with the sixtieth of a grain of the nitrate in pilules three times a day, and did not prohibit spirits. The next day the man felt better, and asked for wine; but the sleeplessness, the want of appetite, and nausea and vomiting still continued, though in a somewhat less severe degree. Four days after the commencement of the strychnine treatment the patient had greatly improved in every way, and was soon afterwards able to resume his work. He continued to take the sixtieth of a grain twice a day for six weeks, and during the four months which have elapsed since the attack he has had no inclination for drink. Upon this case the editor of the *Vrach*, Professor MANASSEIN, who holds the chair of Special Pathology and Therapeutics in the Imperial Military Academy at St. Petersburg, remarks: "There is no doubt that, with abundant materials at hand, observations on the effect of strychnine on different forms of alcoholi[redacted] immediate future be accumulated in c[redacted] may be desirable as a

preliminary to distinguish the different classes of the affection. (1) Anæmic cases (literally "white fever)"; (2) actual drunkenness; (3) constant drinking without symptoms of chronic alcoholism; (4) chronic alcoholism. It is very possible that the effect of strychnine on these very dissimilar conditions may be different, and if all these forms are confounded together, as is done by many writers, it can only lead to confusion when the strychnine treatment is mentioned." Professor MANASSEIN goes on to relate the case of a cook, a very honest, respectable woman of forty-five, who was subject to attacks of insuperable craving for drink, which attacks were preceded by a depressed and highly irritable condition. They gradually increased in frequency, so that latterly they came on about every fortnight. Sulphate of strychnine was ordered in pills from the sixtieth to the thirtieth of a grain after breakfast and dinner. During four months of the strychnine treatment the patient continued in excellent health, not only having no outbursts, but not even experiencing any inclination for drink.

In another Russian medical journal, the *Meditsinskoe Obozrenie*, Dr. PARTSEVSKI gives an account of nine cases of acute and chronic alcoholism treated by means of hypodermic injections of strychnine. Seven of the cases gave excellent results, but in the remaining two cases the strychnine had to be discontinued and chloral substituted. In the majority of cases the treatment began to take effect very quickly on the appetite, sleeplessness, and hallucinations. The trembling of the hands, too, entirely disappeared, and the general irritability subsided. The author says that under no other kind of treatment has he found patients recover so quickly from an attack. Even the blueness of the skin and the puffiness of the face and hands quickly disappeared, and the quantity of urine became notably increased. The dose given is not very clearly stated, but the number of injections required in the different cases was usually from four to eight. In one case only were fifteen necessary. They were given twice a day.

THE visit of Sir HENRY ACLAND to the Pharmaceutical Society and the address which he delivered to the students afford one amongst many illustrations of the good relations now subsisting between pharmacy and medicine. There is no reason why these relations should not continue to exist, and become even more cordial. Though medicine has grown into a science since the time referred to by Sir HENRY, when silkworms, grasshoppers, toads, kittens, &c., were contained in the Pharmacopœia, it has not grown out of the faith in drugs. More than ever it believes in the value of drugs, but more than ever it requires that drugs shall be prepared in a pure state and in an agreeable form. The very progress of medicine involves the progress and development of pharmacy. This progress should tend at the same time to a sharper line of demarcation between the two callings. If a man is to excel in the business of a pharmacist, he cannot dabble in the work of a medical practitioner. There is a fundamental difference in the two callings. The function of the one is to supply pure drugs; that of the other is to study disease and to cure it. In the higher ranks of both callings this distinction is well defined, but there is a little overlapping. Sir HENRY [illegible] the education of the pharmacist does not tend to make him intrude into the domain of the medical man. We think Sir HENRY is on the whole, right. No doubt there are many druggists who assume airs of more knowledge than it is possible for any medical man to have; but the more educated the pharmacist, the more conscious will he be of his inability to understand disease, and the more will he shrink from pretending to do so. Sir HENRY'S praise of the calling of a pharmacist was well deserved. There is no better servant of the public and no better friend of the medical profession than an educated and intelligent pharmacist. The best medical practitioner will learn much from him, and will be most ready to admit his obligations. He must be a rare physician who is not indebted occasionally to the suggestions of those intelligent pharmacists whom he may know and who dispense his prescriptions, and it is impossible to deny that therapeutics have been much advanced by the work of chemists and pharmacists. All this praise, of course, has no application to the druggist who is ignorant of the distinction between his calling and that of a medical man, and who is vain enough to think that a knowledge of medicines enables him to understand their action and their application. Sir HENRY ACLAND spoke of the steps which have been taken by the Medical Council to ensure the best methods of revision of the British Pharmacopœia—referring, doubtless, to the appointment of a committee of the Council, and the allowance of a small grant for this purpose. These are steps in the right direction. Frequent changes in the Pharmacopœia are undesirable, but the existence of many more or less rival publications is some proof that our Pharmacopœia, with all its good qualities, is not such a perfect guide as it might be to the hardworked members of the profession. And considering the responsibility of the Council for the Pharmacopœia, it is but reasonable to regret that it has not used its large funds (for which no very obvious use can be found) more freely in encouraging investigations in pharmacy and therapeutics.

Annotations.

"Ne quid nimis."

THE PUBLIC HEALTH DURING LAST SUMMER.

THE mean temperature at the Royal Observatory, Greenwich, during the three months ending September last was 61·2°, and exceeded the average temperature for this period in one hundred years by 1·6°, although it was 1·5° below the mean temperature for these three months in 1884, when the mean for each month of the quarter was higher than that recorded during last quarter. The rainfall last quarter was 4·9 inches, and 2½ inches below the average. The registered amount of bright sunshine during last quarter was considerably above the average (especially in September), and exceeded the amount recorded in the corresponding period of any of the nine years 1877-85. The Registrar-General's quarterly return will not be issued for a month or two, but a summary of the mortality statistics for the twenty-eight large English towns published from time to time in the weekly return affords a trustworthy indication of the effect of the meteorological conditions above referred to upon the public health. It appears that the annual death-rate in these twenty-eight large towns during the thirteen

weeks of last quarter averaged 20·4 per 1000, and was 0·8 below the mean rate in these large towns in the corresponding periods of the ten years 1876-85. This rate was 1·6 above the rate that prevailed in the summer quarter of last year, but 2·4 below the rate in the far hotter summer quarter of 1884. The rate in London last quarter was 18·7, while in the twenty-seven large towns it averaged 21·8, and ranged from 16·7 in Derby, 17·0 in Bristol and Brighton, and 17·4 in Huddersfield, to 24·7 in Portsmouth and Salford, 24·9 in Manchester, 28·0 in Norwich, and 28·8 in Preston. Variations in diarrhœa mortality in great part explain the wide differences between the above-mentioned rates, the extreme variation being 12·1 per 1000 between the annual rates during last quarter recorded in Derby and Preston. In further explanation, however, of the high rates in some of the towns, it may be noted that in Portsmouth the "fever" rate was 2·03 and the measles rate was 0·82 per 1000; that in Salford the rate from scarlet fever was 1·18; that "fever" and whooping-cough showed fatal prevalence in Norwich; and that measles caused a rate of 2·38 in Preston.

THE INFLUENCE OF MUSIC ON THE CEREBRO-SPINAL SYSTEM.

IT has long been a familiar fact that susceptible, or perhaps we ought to say very impressionable, nervous centres, either of brain or cord, or both, may be influenced by music. Whether the influence exerted is not purely physical—perhaps mechanical and of the nature of vibratory movement, of a nature akin to that exemplified by the phenomena of sensitive and musical flames, and obeying the laws of concord or discord which Newton demonstrated as determining the chromatic and diatonic scales respectively, which Groves further illustrated in the induction of his doctrine of the correlation of forces, and which Tyndall has reduced to practice, may be a moot question, but we cannot doubt that it will sooner or later be settled in the affirmative. However that may be, the fact remains that music does act powerfully on the majority of nervous systems, and there is reason to think that the brain is not alone affected. For example, the movements of the lower limbs both in dancing and in marching are distinctly influenced by music, independently of the consciousness. When the brain at first participates in the excitement produced, it may become engrossed with other matters, and rhythmical muscular movements of the extremities, and in a lesser degree of the trunk, will be continued automatically in harmony with the music. Direct impressions on the cerebral centres are probably transmitted through the auditory centre. Thus monotonous and slow music will exert a calming influence, provided that it be not too slow to be in harmony with the nerve habit of the individual, as in that case it may irritate. It is also essential to the success of any endeavour to bring the brain under the control of music that it should first arrest the attention either by its power or sweetness, and then gradually conduct the organism into harmony with itself. A measured cadence of the sort likely to calm the mind is more likely to augment than to allay irritation, unless it begin with a powerful appeal to the brain in a key which accords with that in which the cerebrum is at the moment itself working. This has not, perhaps, been sufficiently well understood in some attempts which have been made, experimentally, to use music as a remedial measure. So with endeavours to rouse the spirits by music, the opening needs to be plaintive and in the key of melancholy which harmonises with the brain state of the patient. The attention being arrested and the cerebrum reached through the auditory centre, the key must be gradually changed, and the time quickened in such manner as to change the brain state. No great progress will be made with the employment of sound, and form, and colour as remedial agents, powerful as these agents really are, until we dismiss the unscientific idea of "mind," and begin to regard the brain as an organ which, like all other parts of the body, obeys physical laws and performs its function by purely physical processes.

THE SUPPORT OF HOSPITALS.

SPEAKING at Manchester in aid of the extension of the Hospital for Consumption, Lord Derby discussed at considerable length the general question of the maintenance of hospitals. We observe with satisfaction that his lordship, while making due allowance for the particular requirements of so prevalent a disease as consumption, does not view with favour the establishment of too many special hospitals. He truly says that these unattached wards, as we may call them, tend to excessive multiplication, and, when founded on a very small scale, cause waste of funds. Of the various means of defraying the cost of hospital management apart from endowments, he justly attaches the greatest importance to public subscription. Most of our readers will agree with him that rated taxation cannot, with anything like the same acceptance, meet the several conditions of the case. Money can, no doubt, be raised in this way, but the moral effect of such contributions is impaired when the place of sympathy is thus occupied by a legal obligation; while, on the other hand, existing parochial burdens are sufficiently heavy to render their further increase undesirable. If, however, we prefer the method of voluntary giving, it is still very necessary to use some discretion in selecting the recipients of hospital relief. Charity should not be grudged when it is given, but, as Lord Derby says, it is only intended for the poor who need it. All who can, should pay in their measure for medical attention. Our saying this does not, however, imply an approval of the pay-hospital system recently introduced in some quarters, nor do we gather that it is countenanced in the speech before us. Hospital resources are not to be applied in treating the ordinary illnesses of such persons, particularly in the out-patients' department. Nevertheless, there may be times of emergency when no other alternative is possible. In view of this, but more as a matter of common justice and humanity, it behoves every citizen to give what he can afford in support of our public medical charities. Spontaneous action of this kind is a feature of healthy national character. Happily, it is one which is apparent amongst us, though as yet far from being fully developed. The steady, though somewhat tardy, growth of stated annual subscription lists is, in this connexion, a matter for grateful satisfaction. There is still, however, need of a more efficient system of what we may call voluntary taxation, which will bring home to everyone, rich or poor, his personal responsibility to give something, much or little, in aid of the hospital of his own district. This method is indeed partly effective at the present time, and if extensively carried out, would at once relieve the hospitals of much debt, and would preserve the attribute of charity, which so well befits them.

THE REDWOOD TESTIMONIAL.

IT is announced that the subscription list of the Redwood Testimonial Fund will be closed in December. The sum already received is not, we regret to learn, sufficient to carry out the object of the movement, which is the foundation of a scholarship. It is hoped that those who know and value Dr. Redwood's exertions for materia medica, and more especially in connexion with the British Pharmacopœia, will subscribe to the fund. Donations should be sent to the hon. secretary, Prof[illegible] Bloomsbury-square, W.C.

THE HOWARD ASSOCIATION.

THE Annual Report of the Howard Association for 1886 has been published, and, as usual, deals ably with the important question of the best methods for crime prevention and the treatment of prisoners. Speaking generally of British prisons, it observes that during the past year considerable official attention has been directed to promote the efficient operation of two essential objects—viz., a deterrent influence upon offenders in general, combined with efforts to reform criminals individually. The considerable proportion of prisoners, both male and female, inveterate misdemeanants, who revisit the prisons scores or even hundreds of times in succession, at excessive cost to the community, and who are neither deterred nor reformed, has long been a scandal, and shows that in this respect at least our present system is a failure. Officialism is slow to perceive and slower still to act, but we are pleased to find that at length a remedy may be sought in wiser legislation, and also in the further development of those moral and religious agencies which already have been established, but which require more active support and determined sympathy from the general public before they can make definite headway. A proper classification of prisoners and an intelligent discrimination in prison discipline is much to be desired, and would, if carefully systematised, strike at the root of the two evils mentioned. We have often insisted that, whilst prison discipline in England is hardly sufficiently severe on hardened criminals, it is much too hard on those who are committed for technical offences or breaches of order. This was a point on which the late Dr. Wakley felt strongly, and we are pleased to see in the present report a touching tribute to his action in this respect. Speaking last year with regard to the necessity of making some distinction between prisoners committed for political and religious offences and those sent to gaol for actual crime, THE LANCET went a step further and pointed out that even in the case of criminals the disproportion in the severity that exists between short sentences of fourteen days and those of three or four months is very great, the amount and quality of food and certain other points of prison discipline being much more severe in the case of the shorter sentence as regards its effect on the prisoners' health and power of endurance than in that of the longer sentence. So well, we believe, is this difference known among habitual criminals that we are informed they will "go" for an offence that brings the longer penalty. "If they escape, the greater the plunder; if caught, the better they are fed." The same want of classification that is experienced in prisons is felt to even a greater extent in reformatories; the mutinies we so frequently hear of as occurring in these establishments probably arise from this cause, and there is undoubtedly great need of separating the younger from the older youths in these establishments. The Report further deals with other interesting particulars concerning our prisoners and methods of crime prevention—such, for instance, as the scheme for the "Conditional Release of First Offenders," observations regarding the "Boarding-out, Emigration, Temperance, &c." in connexion with the question of juvenile pauperism, and an abstract of the correspondence and information obtained both at home and abroad on the subject of capital punishment. In conclusion, the Report, in summing up the losses to the Society during the year, speaks in feeling terms of the death of Mr. Samuel Morley, and also of the deaths of three other efficient and liberal supporters—Mr. Balfour of Liverpool, Mr. Hugh Mason of Ashton-under-Lyne, and Mr. Allen of Dublin. Owing to the continued depression of business the financial year of the Association closes with debt, and the income has [illegible] diminished as to materially limit its operations and to cause grave anxiety as to its future. This should not be. The Howard Society stands between the criminal and the rigid officialism of a department, and until the representatives of the press have the right of visiting these institutions and reporting from time to time on their management, this Society acts as a wholesome check on the routine callousness of officialism, and brings to light any abuses that may arise.

PHARYNGEAL AND LARYNGEAL NYSTAGMUS.

IN our last issue we published some notes, in the form of a letter, on rapid rhythmic contractions of the pharyngeal and laryngeal muscles associated with rapid rhythmic contractions of the ocular muscles, in a case of cerebellar tumour in a girl aged twelve years. The importance of this nystagmus of the pharyngeal and laryngeal muscles lies partly in the interest attaching to the phenomenon and partly in its suggestiveness. In the case in question great attention was paid to the state of the rest of the nerves of the body, but nothing in the same nature as nystagmus of any other muscle was observed; nor, so far as we know, was there any rhythmical recurrence of sensation in any sensory district. The rate of the rhythm in the pharynx and larynx was perfectly synchronous with the rate of action of the muscles of the eyeball. The ocular nystagmus was of a mixed vertical and horizontal description. It is hardly likely that the symptom which Dr. H. R. Spencer discovered in this case of cerebellar tumour is of common occurrence either in tumours of the brain or in any other disease of the central or peripheral nervous system, but its present recognition will doubtless stimulate observation, and may lead to a still further extension of knowledge. The symptom is a genuine one, and evidently not dependent on a combination of conditions whose balance is easily upset, for the nystagmus has been in constant active operation for at least two months. The rate of the pharyngo-laryngeal contractions, like the synchronous nystagmus of the eyeball, is 180 per minute. It is worth while remembering the circumstance that the muscles which are the seat of the rapid nystagmus in this case are sometimes employed volitionally, and at other times automatically, or reflexly. Another feature of the case to which Dr. H. R. Spencer alludes is the rate of the pulse, which is unaccountably frequent, being 100 per minute. It may be that this is related in some way to the action of the pharyngo-laryngeal muscles, whose motor fibres in the vagus are derived, in part at least, from the spinal accessory nucleus, which is also believed to preside over the rate of action of the heart.

PAROCHIAL AID IN URGENT ILLNESS.

THE liability to incur bad debts is one of the grievances which are felt in a peculiar degree by members of our profession. Where the failure to pay expenses of treatment arises from deliberate neglect, the remedy is of course in the practitioner's hands, though as a matter of fact recovery of charges in a court of law is felt by many to consort badly with professional requirements. Where, again, the poor are attended in their homes, there is apt to be serious consumption of time without any chance of remuneration. It has been proposed to meet this latter difficulty in a somewhat novel manner. According to this plan first aid to the sick poor should be afforded by the police, who would on application procure the services of a neighbouring practitioner. The fee for a first attendance would be defrayed at the public cost, and the practitioner would therefore be to that extent ensured the reward of his labour. Medical men are not backward as a rule in placing their services at the disposal of their fellows in cases of emergency. To a considerable extent humanity requires that they should be ready to do

this without prior stipulations as to fees. It must also be remembered, however, that parochial guardians are not free from responsibility as regards many of the poor in a given district. The ordinary method of application for medical assistance through a relieving officer is also in some case inconveniently tedious. While therefore we doubt if the plan of aid in emergencies, which has been referred to, could be made to work in its present shape, we can enter into the feeling of the proposer, and agree with him that the moral right to remuneration by the parish for attendance on the poor in sudden and urgent illness should find some legal expression.

ROME, IN RELATION TO CHOLERA IMPORTATIONS.

TOGETHER with news of a still further reduction of cholera in Italy and in Austro-Hungary, there comes intelligence of the appearance of a disease in Rome which, to say the least, is of a choleraic type, the occurrence taking place simultaneously with a migration of working-people from the country districts. One case has terminated fatally, but it is by no means clear whether the disease has been actual cholera, or whether it has simply been autumnal diarrhœa of a severe type. It would be singularly unfortunate if cholera made any headway in Rome. In 1884, although the disease gained access to the city, it failed to spread to any noteworthy extent, and this fact, associated as it was with the existence in Rome of sanitary circumstances so vastly superior to those prevailing in most Italian towns and cities, unquestionably gave an impetus to sanitary work in the peninsula generally. Rome has an excellent and abundant water service, and the old wells were bricked up and thus abolished on the first rumour of cholera two years ago; hence there is little to fear on the score of water. As to sewerage, Rome is making substantial progress. It is true that the new system of culverts now being carried through the city is not in every respect such as to secure from leading British engineers unqualified approval; but still the advance made is very great, and when the scheme with its outfall is completed, Rome will be in a better position than it ever has been before. But in the matter of house drainage there is room for vast improvement in the Eternal City. Disconnexion and through ventilation of house drains is hardly known of, and many of the drains are badly-constructed brick culverts, which allow of the deposit of contents. There is therefore room for some apprehension as regards cholera, but it is much to be hoped that the labours of the local authorities, which were so successful in 1884, will not be less so in 1886 if cholera has really found its way into the city. Rome has, with justice, been compared with other cities as to the effect of efficient sanitary administration in controlling the spread of cholera, and if she can, by continued sanitary progress, maintain her immunity from the disease, notwithstanding recurring importations, her example may be expected to have considerable influence on the immediate future of the health of Italian cities.

PULSATING TUMOUR OF THE HEAD.

THE living specimen shown by Mr. F. Treves at the Clinical Society last week attracted much notice from the members. There appeared to be at least two pulsating swellings about the head, and each of different natures. One of these, situated in the middle line in the occipital region, appeared from the evidence adduced by the author to be of a venous nature, and in direct communication with the superior longitudinal sinus,—whilst the swelling that pulsated in the mastoid situation gave the signs of a cirsoid aneurysm. The aspect of the face was rendered peculiar by an apparent protrusion of the eyeballs, and the odd look of the countenance was enhanced by a difference in the size of the two palpebral fissures, and still more by an asymmetry of the face, the combined effect of the smaller size of its left half and a want of power in the muscles of the same side. In ordinary demeanour the protruded globes of the eye were at apparent rest, no obvious movement being perceptible; but in the act of looking to one or other side the globes were agitated by a side-to-side movement partaking of the characters of a moderately rapid nystagmus of the horizontal kind. In addition to these characters, the case was rendered more complicated by the presence of some degree of blueness of the hands, which felt cold—a double condition which Mr. Treves said was intensified by cold weather and, we believe, by the application of artificial cold. The patient in whom these features were observed was an intelligent lad who worked in a printer's office. In the upright posture the boy did not experience any subjective troubles, but on lying down he would be annoyed by the throbbing and rushing of the pulsating tumours, and sometimes his comfort was disturbed by headache, giddiness, and vomiting.

SUMMER DIARRHŒA MORTALITY IN 1886.

ALTHOUGH the mortality from infantile diarrhœa showed a marked and unusual excess in the first week of October, the mortality from this disease in the summer of 1886 will be measured by the recorded deaths from this cause in the thirteen weeks of the quarter ending with September. The mean annual death-rate from this cause during this period in the twenty-eight large English towns dealt with in the Registrar-General's weekly return was equal to 3·6 per 1000, against 2·1, 3·9, and 2·0 in the corresponding periods of the three years 1883-85. Diarrhœa mortality was relatively greater during the past summer than in the same period of 1884, if due allowance be made for the fact that in the summer of 1884 the temperature was considerably higher, and that considerably less rain fell than in the summer just ended. It cannot be assumed that the general sanitary condition of these towns was lower in the past summer than in the summer of 1884, and therefore it is evident that there are other factors than temperature and rainfall that govern the general fatal incidence of summer diarrhœa in our large urban population. The explanation of the wide variations in the death-rate from diarrhœa in different towns in the same summer season supplies a still more difficult problem, which has long been under investigation by the medical department of the Local Government Board. During the thirteen weeks of last quarter the death-rate from diarrhœa in London was 3·0, against 3·1 in 1884; while in the twenty-seven provincial towns the mean rate was 4·0, and was rather higher than the rate in those towns in the summer of 1884. Among these provincial towns the lowest diarrhœa rates were 1·1 in Bristol, 1·4 in Huddersfield, 1·5 in Halifax, 2·2 in Plymouth, and 2·5 in Portsmouth and in Derby; the highest rates were 5·4 in Salford, 5·5 in Preston, 6·2 in Leicester, and 8·2 in Norwich. All these four towns have habitually high diarrhœa rates, but compared with the rates in 1884, those recorded last summer showed a marked increase in Norwich, whereas they had considerably declined in Preston and Leicester. The low rates in Huddersfield and Halifax, both manufacturing towns, are in striking contrast with high rates in Leicester and Preston, also manufacturing towns. It may be noted, too, that the rate in Blackburn did not exceed 2·8, while in Preston, as above-mentioned, it was nearly double—5·5. What is the explanation of this wide variation between the diarrhœa rates in two neighbouring manufacturing towns of Lancashire during the same summer? It is for light upon these points, in connexion with the causation of [illegible] diarrhœa, that we look for the results of [illegible] Board investigation.

DIRECT REPRESENTATION IN SCOTLAND AND IRELAND.

THE Medico-Chirurgical Society of Aberdeen, Professor Struthers presiding, have passed two resolutions on the subject of Direct Representation. The first highly approves such a change in the law and in the constitution of the Medical Council. The second is as follows:—"In view of the approaching election of a Direct Representative for Scotland on the Medical Council, the Society is strongly of opinion that, in view of the very full representation already accorded to the medical and surgical corporations and the universities, the Direct Representative for Scotland ought to be one who is unconnected with the governing body of any of the corporations, or with the professoriate of any of the universities." The Direct Representation principle in Scotland seems to have much better chance of success than in Ireland. Two representative general practitioners are in the field. A third, Dr. Morton, is the new president of the smallest medical corporation in Scotland, which is already represented by a special and able representative, Dr. McVail, who, in the unlikely case of an emergency to which he was unequal, might rely on the assistance of Dr. Fergus, who has just left the chair. This attempt to secure seats for three officials of the Glasgow Faculty ought not to succeed. It is almost as bad as the attempt of the Dublin magnates, who have hitherto monopolised the five Irish seats, to snatch the sixth from the practitioners of Ireland. It is gratifying to see Professor Struthers, representing one of the highly represented bodies, giving his countenance to the thorough application of the principle of Direct Representation.

THE HISTOLOGY OF STRIPED MUSCLE FIBRE.

MR. MELLAND, Platt Physiological Scholar in Owens College, publishes an essay, in the studies from the biological laboratories of the Owens College, upon the Histology of Striped Muscle Fibre, which contains several points of interest. Starting with the admission of the essential identity from a physiological point of view of all those tissues which in a special degree possess contractility, he notices the remarkable histological peculiarity of the voluntary muscle fibre, which is in reality a cell, in presenting a characteristic transverse striation. Yet he thinks that his own observations tend to prove that the striated muscle fibre agrees fundamentally with the other contractile tissue elements, in containing an intracellular network, which is specially differentiated and more regularly arranged. He has observed this network in the fibres of dytiscus, the bee, crayfish, lobster, frog, and rat, prepared by a special method of gold-staining, the network being the only part of the fibre stained with gold. It may also be specially stained by treating the fibre with acetic acid, and subsequently staining with hæmatoxylin. It may be demonstrated, though not so completely, in the living fibre, and in acetic and osmic acid preparations. The method of gold-staining he has adopted is as follows:—Decapitate a dytiscus, open the thorax, remove a portion of a leg muscle, and place into 1 per cent. acetic acid from five to fifteen seconds, then into gold chloride solution of the strength of 1 per cent. for forty-five minutes, and then leave in a solution of formic acid containing 25 per cent. for forty-eight hours in the dark. Finally tease and mount in glycerine. Mr. Melland, it may be said in passing, illustrates his paper by a carefully drawn plate on which are many figures of the muscles of the above-mentioned animals. His method of preparation has a great tendency to soften the fibre and to cause it to expand on compression by the coverslip, and it also renders the fibre apt to split into transverse discs. Careful examination has satisfied him that an intracellular network may be demonstrated in striated [illegible] arranged in the form of a transverse network, which crosses the fibre, separating it into compartments, and united to the sarcolemma. Running longitudinally down each compartment, and joining the dots at the intersection of the fibres of the transverse network, are a series of fine rods. The network consists of an isotropous material, and is more highly refractile than the rest of the muscle substance, which is anisotropous. The matrix, or substance which occupies the interstices of the network, is of far greater bulk than the network. It is homogeneous throughout; nevertheless, it may be looked upon as being partially divided into columns or fibrils by the longitudinal bars of the network, and partially into discs, the contents of muscle compartments by the transverse network. By the action of spirit the matrix becomes split into fibrils, the sarcous substance shrinks, and the homogeneous mass now separates into fibrils along the lines of greatest weakness; that is, along the guide lines formed by the longitudinal bars of the network. Then fibres may again divide transversely at the horizontal networks, producing sarcous elements, which are thus, as described by Klein, a post-mortem phenomenon. Mr. Melland explains Cohnheim's areas as the appearances produced by coagulation and splitting of the matrix along the guide lines formed by the transverse network. They represent an end view of sarcous elements, and are also a post-mortem phenomenon.

CLINICAL FACTS IN NOVELS.

IN an interesting paper in the *Nineteenth Century* for October, Dr. Nestor Tirard discusses the subject of Diseases in Fiction, and, inferentially at least, pleads for greater realism or more accuracy in the use made by novelists of disease to kill off their characters. We are not quite sure that, if it were worth while to go into details, we should agree with the author in all his criticisms. For example, we think he is a little hard on Dickens, and we do not perceive the difficulty of understanding the illness of Dick Swiveller when nursed by the Marchioness. Nor are we prepared to endorse the suggestion that such maladies as locomotor ataxia, and neurasthenia as treated by the Weir-Mitchell process, might be further utilised by the writers of fiction. We fail to see the "picturesque side" of the antiseptic treatment, and we do not think "the prophylactic action of copper against cholera" promising material. These are, however, matters of detail, and doubtless it would be well for those who supply the reading public with materials for its amusement to be so far accurate as to point a moral and adorn a tale in such fashion as to avoid offending the intelligent susceptibilities of those who, knowing something of disease, find relief, if not delight, in the perusal of works of fiction. Meanwhile, it must be confessed that we are not of the number of those who yearn, above all things, for realism in the drama and romance. This is the age of "matter-of-fact" philosophy, and every question resolves itself into one of statistics. We venture to think that one department of Art, at least, might be kept free of the bonds of truth and realism. There are many ways of conveying instruction, and all we ask is that there shall not be a total suppression of the imaginative faculty. It is a positive relief sometimes to get out of the range of that exacting fusillade of facts—biological, medical, and sanitary—which the popularisation of science has developed to very formidable proportions. We are not sure that it is the sole mission of Art to copy Nature. In fiction, as in painting, a De Foe may emulate a Correggio, and by so doing fulfil a purpose in no sense less noble and elevating than that which animates the painfully precise artist who devotes a whole fortnight to the realistic elaboration of a picture of a broomstick. It really makes very little difference how the novelist kills off

his characters, and, in no spirit of cynicism, may we venture to observe that a story is not always the less interesting because of its improbability. Nevertheless, there is much to be said on the side of the argument propounded by Dr. Nestor Tirard, and we do not doubt that the novelists generally, and a certain, probably a very large class, of their readers, will be greatly indebted to him for the attention he has bestowed on an interesting subject, and the prominence which his paper cannot fail to secure for it.

ANEURYSM OF THE ARTERY OF THE SYLVIAN FISSURE.

A CASE of aneurysm of the artery of the Sylvian fissure has been reported in a Norwegian medical journal by Dr. A. Linboe. The patient, a woman aged forty-nine, came to Gaustad Asylum with melancholia. She had had a cardiac affection for many years. Besides melancholia, she complained at times of pain in the head and a feeling of irritability. There was some distortion of the face, the angle of the mouth being drawn down. One afternoon the patient became suddenly ill, entirely losing consciousness. A pufliness of the cheeks was observed. The left pupil was dilated and did not react to light; the right pupil was also reactionless. There were slight convulsions, and the woman died at 11.45 P.M. The distortion of the face, which had disappeared, was again present immediately after death. Eleven hours afterwards a necropsy was made. The anterior portion of the right parietal convolution was covered with a thin layer of coagulated blood. Over the whole of the left hemisphere there was a more or less thick layer of blood, especially in the left Sylvian fissure, where it had a thickness of about five centimetres; in the interior of this, a nodular aneurysmal enlargement of the artery was found about three centimetres in diameter. There was but little atheroma in the trunk of the artery of the Sylvian fissure on the left side, but a considerable amount of it on the corresponding artery on the right side.

THE "GRAPHIC" ON MEDICAL STUDENTS AND MEDICAL STUDY.

A VERY interesting paper on Medical Students and their Work, with good illustrations, fitly found insertion in our contemporary, the *Graphic*, of Oct. 2nd. The hospital from which the writer drew most of his facts was St. Thomas's. He writes under the initials "W. H. S." We commend the paper to all medical students; not that we agree absolutely with all the statements of the author. Some are open to question. One, for example, in which he says that the medical profession is far from being overcrowded. We cannot but think that such an estimate is only possible to one who occupies a somewhat select place in the profession, or whose life is exceptionally serene. The run of men in the profession find its paths somewhat crowded, and competition keen, and occasionally undignified. In some quarters methods of obtaining practice are resorted to which can only be explained by great pressure of circumstances, and then cannot be excused. Besides what we may call painful evidence of overcrowding, we have some statistical facts of the same import. Thus the number added to the profession yearly exceeds by nearly 300 the number falling out of the Register by death &c.; and the number now annually entering the profession exceeds by over 300 the numbers which used to enter it nine or ten years since. The medical profession is still not a bad calling for those with a special talent for it, but it will be more and more a stern vocation for strong and serious natures only. The author's views on what he calls "the grandmotherly interference with liberty of students" are worth consideration; but he treats too lightly the risks of modern Babylon to the young and inexperienced student. The surfeit of confectionery is a very good cure for the confectioner's new apprentice, but all temptations are not to be treated on this principle without grievous consequences, and the collegiate care of youths in medical schools is a subject that deserves more attention than it has received. With a few such demurs as these the paper in the *Graphic* is to be much commended. Happy the school that has such an exponent of its claims, and the pupils that have such a guide. It will not be his fault if they fail of scholarships and hospital appointments, or if they fail to acquit themselves like men in the after-race of medicine.

EXHAUSTION FROM VOMITING.

AN inquest was held by Dr. Danford Thomas on the 13th inst. at the Crowndale Hall, St. Pancras, touching the death of James Betts, aged seventy-six. Deceased had suffered from a large rupture for many years. On the 5th inst. he complained of pain in the stomach, but slept through the night. On the following evening he was seized with vomiting, and being unable to return the bowel from the sac, he was taken to the North West London Hospital, where he vomited three times, and died from exhaustion eight hours after admission. The house-surgeon reduced the rupture without difficulty. At the post-mortem examination there was found to be extensive senile degeneration of the aorta and aortic valves. The prostate was enlarged; the stomach was congested, and showed a patch of capillary hæmorrhage, the result of the act of vomiting. About a foot and a half of the small intestine was strongly congested, and had evidently been nipped in the rupture, but the constriction had fallen short of that necessary to cause gangrene of the bowel; in fact, it was at first doubtful if there was not another cause of the vomiting, and so of the death; but on reflection it was decided that, considering the deceased's advanced age, and the readiness with which vomiting is excited by moderate nipping or twisting of a coil of intestine, the issue was due to partial strangulation of the hernia inducing fatal vomiting. These cases are of interest as well from a medico-legal as from a surgical standpoint. The onset of vomiting might be supposed to indicate the action of some irritant in the stomach, and so the theory of poisoning might arise. Such a supposition would gain a fictitious support from the fact that the stomach was congested. The mechanical effects of vomiting are not to be mistaken for the brighter and more diffused redness caused by chemical irritation of the mucous membrane. Whenever the condition of the stomach is at all of equivocal interpretation, the strictest search should be made for natural causes of death, and all antecedent pathological changes are causes in greater or less degree.

DREAMS AND THERAPEUTICS.

WHICH of us—the most philosophical of us—is proof against a good mysterious dream? Where Abercrombie and Brougham found so much to enchant and interest we may occasionally explore, even in these matter-of-fact days on which we have fallen. Those who wish to have their waning faith in dreams stimulated, and to enjoy a very curious story besides, will do well to read a paper in the October part of the *Leisure Hour*, entitled "A Mysterious Interposition," by J. L. Cotter, M.D., rector of Burmarsh, Hythe, Kent. This gentleman, at once a physician and a divine, vouches for the truth of his narrative, in which he records how, when in medical practice in Ireland, he dreamt three times that he was summoned to see an old gentleman extremely ill, [illegible] seemingly dying with dyspnœa; how he was so [illegible] ion as to take it for a

sign and alter the round of his duties so as to be in the way of anything that might turn up; and finally, how he was actually summoned to a patient exactly corresponding in all his features, symptoms and environment, to the old man he had seen in his dream. This old gentleman suffered with acute pneumonia, from which he was recovered by a happy use of two apparently, but not necessarily, divers remedies—port wine and phlebotomy. The reverend author takes occasion to vindicate the use of the lancet, and to say that he cannot understand the discredit into which it has fallen. We have certainly learnt to bring our patients through this disease more successfully than when phlebotomy was practised freely and indiscriminately; but there is nothing in this fact to detract from the extremely interesting narrative of Dr. Cotter.

A COLLECTION OF PINE LEAVES IN THE BRONCHI CAUSING REPEATED HÆMORRHAGE.

DR. AXEL KEY mentions in the *Hygeia* the case of a man, thirty-six years of age, who had suffered for seventeen years from violent hæmorrhage from the lungs. He died in the Serafim Hospital, Dec. 1st, 1885, after a short residence there. At the post-mortem examination the body was found to be robust, and not emaciated. In both of the larger bronchi there were a number of circumscribed blood coagula. The right lung was unaltered; in the left there was a slight enlargement of a smaller bronchus, with induration of the walls and immediately surrounding lung tissue. In the cavity of the dilatation there was a quantity of coagulum. Outside the cavity there were six pine leaves partly massed together, but with the points free; the leaves were of a brownish-grey faintly changing into green, stiff, and with sharp points. The marks of the points appeared on the mucous membrane, and were several millimetres long. The lung was in other respects healthy. The leaves were, in the opinion of Dr. Key, the cause of death, owing probably to the fact that latterly they had embedded themselves more deeply in the lung, or that their position had changed to a new and more dangerous place.

MEDICAL MEN AND DEATH CERTIFICATION.

WE are constantly warning medical men against the error of writing certificates of death in cases which they themselves have scarcely seen during life, but which have been attended by an unqualified assistant acting under their authority. Another case in point is reported: that of Mr. George Wadley, whose death was the subject of an inquest by Mr. A. Braxton Hicks. It appears that nine days before his death Wadley had gone to "Dr. Davenport" at the Dispensary in Peter-street, Westminster, who again saw him on the day of his death. When he was dying Mr. John Hopkins Pugh was also called in. When the certificate of death was wanted, Mr. Day of East Dulwich, and the proprietor of the Peter-street Dispensary, filled it up. He admitted he had made a mistake in doing so, but said that nearly all the practitioners of Dulwich had at times employed unqualified assistants. Mr. Davenport defended the certificate on the ground that it was usual for principals to regard the attendance of unqualified assistants as their own, and to certify on the strength of having seen the patient during the last illness, as was the case here. The coroner did not think so lightly of this practice; he considered there had been a violation of the Registration Act, and very properly determined to refer it to the Public Prosecutor. Mr. Davenport had the less excuse for being concerned in such a case, as he has had a previous experience of the sort. Mr. Day's attempt to defend his position in this case in letters to the papers is not very [illegible]. He does not deny that the principal [illegible] venport, and that he is unqualified. One or two visits to a man so ill by the qualified principal do not meet the requirements of the case, or justify the signing of a certificate. To say that unqualified men must see cases does not excuse leaving them in principal charge in urgent circumstances.

The *Leeds Evening Express* of Oct. 4th contains an account of two inquests in which two children were attended by Mr. W. J. Garrett, not legally qualified, but acting as *locum tenens* of Dr. R. W. Henderson. The certificates were signed by Dr. Henderson, and from the report it would seem that before leaving for his holiday he had seen both these children and left signed certificates ready for use. Dr. Henderson defended this by saying they were mere matters of form, as the cases were incurable. But we concur with the coroner in his unwillingness to accept this argument as a sufficient defence. The system is not fair to the public or to the poor, who are misled by it. Nor is it fair to regular members of the profession, who acquire their qualifications with much labour and cost, and ought not to be opposed by unqualified persons.

VACCINATION CENSUS.

THE so-called vaccination census is progressing, and a number of villages have been asked to express their opinion as to the value of vaccination, and to record their experiences of its effects. The alleged results would be amusing were they not calculated to prepare more susceptible material for small-pox. The publication of a statement that five deaths, the loss of a limb, fits, sore eyes, and a large number of other ailments, occurred from vaccination in less than one thousand families thus questioned, will doubtless be accepted by unfortunate rustics as a reason for leaving their children susceptible to small-pox, and they will fail to see in this foolish story the hand of the fanatic, who is regardless of the terrible calamity to which he exposes those who listen to his teachings. If the sufferers from this folly were adults, who might more fairly be expected to submit to the penalties attendant upon their errors of judgment, there would be less reason for regret; but the victims are little children, who have no voice in the decision whether they shall be protected against a terrible scourge, and it is for these that every effort should be made to counteract the baneful teaching of those who publish such misleading information.

THE ALIENIST CONGRESS AT SIENA.

THIS fine old town among the few unspoiled relics of mediæval Tuscany—was on the 19th ult. the scene of an interesting congress—that of the Italian alienists, who had assembled to the number of forty from all parts of the peninsula. The sittings were held in the Palazzo Municipale, or town hall, and concurrently an exposition of asylum industries and apparatus was on view in the University buildings. The president was Dr. Buonomo of Naples, and among the principal speakers were Professors Tenchini of Parma, Chiverny of Milan, Bianchi of Naples, Morselli and Tanzi of Turin, Ronciti of Siena, Sadem of Pisa, Corradi of Pavia, Lombroso of Turin, and Ferri, who holds the chair of penal law at Siena. The senator, G. B. Verga, read an elaborate paper on "Mania Moralis," and he was followed by Dr. Brajon with a note on a "Case of Moral Mania consequent on Mania Furiosa." An animated and most interesting discussion ensued on the legal bearings of the question, till an adjournment had to be imposed to admit of the other items of the programme being overtaken. Dr. Algeri's paper on the "Heirs of Crime, of Madness, and of Alcoholism" was heard with marked attention, as also was Dr. Frigerio's on "Cerebral Localisation" and Dr. Majorff's on the "Curability of Puerperal Phrenosis." The

contribution that commanded most interest was a very brilliant memoir by Dr. Vigna of Venice on "Music as an Element in the Psycho-therapeutics of the Insane," the publication of which will secure it many besides professional readers. A striking paper on "Mania Transitoria" elicited much applause for its author, Professor Venturi, and was followed by a discussion at the instance of Professor Lombroso, who, joining issue with Dr. Venturi, maintained transitory mania to be a variety of epilepsy, and then reopened the entire question of moral insanity considered with reference to education, responsibility, and crime. The proceedings, when published, will attest the interest and the study which this most fascinating problem commands among the alienists of Italy. The congress closed after a week's sittings, diversified with visits to the 'Esposione Freniatrica" and the local asylum, where the inmates gave a highly successful concert, vocal and instrumental. An ode of welcome to the congressists, composed by one of the convalescent patients and set to music by the Maestro Donatini, was very touching.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE statutory annual meeting for the election of office-bearers was held on the 4th inst. Dr. James Morton was elected president, Dr. Alexander Robertson visitor, and Dr. James Dunlop a member of the Council. For the Examinership for the Licence there were this year two contests. In the first Dr. James A. Adams succeeded in securing his reappointment as Examiner in Anatomy, his opponent being Mr. J. T. Carter, Lecturer on Anatomy in the Western Medical School; while in the second Dr. James M. Milne, Lecturer in Chemistry, replaced Dr. John Clark as Examiner on that subject. For the first time a special board was elected to examine for the Fellowship, the examination hitherto having been conducted by the Board for the Licence. On the Dental Board, Dr. John Dougall was elected an Examiner, in room of Dr. Alexander Lindsay, resigned. The system of nomination for office under the revised rules came into operation for the first time, with the result of considerably abbreviating the proceedings.

THE AFTER-DAMP OF GUNPOWDER.

THE recent serious disaster from the inspection of a quarry in which a large charge of gunpowder had just been fired has been the occasion of some erroneous criticism. Thanks to modern research, and above all to the labours of Sir Frederic Abel and his colleagues, we now know a great deal about the explosion of gunpowder under pressure, and it is very easy to explain the accident. The explosion is by no means so simple a chemical change as was formerly supposed. About 43 per cent. of the gunpowder passes at the moment of explosion into permanent gases, the remainder being converted into compounds which, although to a great extent volatilised by the intense heat, easily condense into the solid form. The average composition of the gases may be approximately stated as follows:—Carbonic acid 26·5, carbonic oxide 3·5, sulphuretted hydrogen 1·5, nitrogen with traces of other gases 11·5, making up the 43 per cent. The noxious character of this gaseous mixture, from which we omit the imperfectly condensed solids, is manifest. Carbonic acid is highly poisonous, but carbonic oxide and sulphuretted hydrogen are deadly, and no one can wonder that persons suddenly exposed to an atmosphere impregnated with them suffered severely. We can, indeed, only wonder that the reckless conduct described in the daily papers did not lead to a greater number of deaths.

PRESENTATION TO DR. ALFRED CARPENTER.

SOME of the leading inhabitants of Croydon assembled on Tuesday, the 5th inst., to do honour to their distinguished townsman, Dr. Alfred Carpenter. As President of the Literary Institution, Dr. Carpenter has now and again gratified his love of hospitality by entertaining its members at pleasant *soirées*, and on the third of the series of these local gatherings, it was determined to utilise the occasion by presenting the doctor with a worthy token of the esteem in which he is held and of the widely-felt sense of the value of his services as well to Croydon at large as to the institution over which he has presided for thirty years. The testimonial took the form of a marble bust and an illuminated address, to which were appended about 100 signatures, including the names of the Archbishop of Canterbury, the Mayor of Croydon, and other prominent gentlemen. The town has done itself honour by thus honouring one of its greatest benefactors.

CEPHALIC MENSURATION.

DETERMINATIONS of the shape and size of the skull with a view to ascertaining the degree of intellect are, in our opinion, of but little value. If the cranial cavity be very small or the head very large, some statement may be pretty safely hazarded as to the intellect of the owner of the micro- or macro-cephalon. But we are never free from discussions of the kind. And here is a new method of cephalic mensuration going the round of the French papers. M. Luys is the author of the method, though we do not perceive where the novelty lies. We are under the impression that the skull has been measured in its every diameter, and should have thought that it would have been a safe challenge to make that no one could be inventive enough to discover a new way to ascertain the cranial dimensions. Of course there are new instruments meant to measure directly the cephalic outlines. These instruments are adapted for taking antero-posterior, circular, and binauricular diameters. "The fronto-occipital cephalometer gives the antero-posterior diameter of the cranium, and the vertical and the oblique anterior and posterior diameters may also be taken, and thus enable the differences of the cerebral mass to be estimated"!

ATHLETICS AND WOMANHOOD.

IT has been suggested to us that the effect of the athletic exercises now common among girls, if these are really beneficial, should have begun to appear in the physique of women of the present day, and to show itself in greater fitness for the duties of maternity. Medical men in practice might, no doubt, throw some light upon this question. To our own mind there seems good reason to believe in the generally beneficial effect of all such means of educating muscular power, if they be used in moderation. Besides their intrinsic property of increasing vigour and agility, they necessitate a greater freedom from the rigid restraints of dress which were usual twenty years ago. They imply, moreover, a liberal allowance of fresh air, and, by encouraging vital changes throughout the body, combat that dislike to food which is so common among young girls of listless habits. Thus in various ways their tendency is to strengthen and stimulate the whole system. There can, we think, be little doubt that the woman who has grown up under this wholesome training is the fitter in consequence to bear the lot of her sex in married life. Her nerve will be stronger, her muscular power greater, and each natural function proportionately more active. It is indeed not very clear at first sight that such a contingency of childbirth as the use of instruments in delivery can be "[illegible] in such cases other factors

must be considered, but there are doubtless some conditions of structure such as those dependent on spinal mischief which would be favourably affected by gymnastic movements and games of like character. One thing, however, must not be forgotten—namely, that moderation in amount and fitness as to times are essential to the success of all such training.

THE WEST LONDON HOSPITAL.

THE members of the staff of the West London Hospital, to the number of fifteen, dined together at the Holborn Restaurant on Tuesday last, Dr. Hood, the senior physician, being in the chair. The occasion was an auspicious one in the history of the hospital, inasmuch as it was the first upon which such a gathering had taken place; and the chairman, in proposing the toast of "Prosperity to the West London Hospital," remarked that it had been unanimously agreed to make the social meeting which was being inaugurated that night an annual one, to be held on the second Tuesday in each October. Messrs. Edwards and Dunn, the secretaries for the dinner, replied. Mr. Keetley proposed "The Health of the Chairman," and Dr. Hood briefly replied. Subsequently, upon the invitation of Mr. Bruce Clarke, the members adjourned to his residence, in order to take part in the presentation of a tray and tea-set to Mr. Keetley, which had been subscribed for by members of the staff, on the occasion of his marriage. The tray bore the following inscription:—"Presented to C. R. B. Keetley, F.R.C.S., by members of the staff of the West London Hospital, on the occasion of his marriage on August the 5th, 1886, in recognition of his zeal and enterprise as a surgeon, as of his good fellowship as a colleague."

INFLUENCE OF COLD AND TOBACCO-SMOKING ON THE RATE OF DIGESTION.

DR. CHUDNOVSKI publishes in the *Russkaya Meditsina* an account of a series of observations made on twelve soldiers in a military hospital, who were perfectly healthy with the exception of slight injuries, with the object of determining the effect of cold applications to the epigastrium upon the rapidity of digestion. The stomach-tube was of course freely used, and the completion of digestion was taken to be marked by the disappearance of solid particles in the gastric contents, as revealed by drawing them up through the tube. The author found that when ice-bladders were applied next the skin over the region of the stomach digestion was retarded in nine out of the twelve cases. Six of the men were smokers and six non-smokers. In the former the time required for digestion averaged seven hours, while in the case of the non-smokers the mean period of digestion was only six hours.

DENTAL EDUCATION.

THE address on dental education read at the last meeting of the British Dental Association by Mr. Morton Smale, the indefatigable and popular Dean of the Dental Hospital of London, should be not only perused but studied by all parents desirous of making their sons dental surgeons, and we only regret that we have not space to print it *in extenso*. Speaking of those who are ashamed of their vocation, because, forsooth, there are black sheep on the Register, he very truly remarks that they might with equal justice be ashamed of their humanity because there are members of it who habitually disgrace it; the best of mankind, however, "walk *not* on the other side," but endeavour by good example and providing education to raise the renegades to a higher standard of nobility and self-respect. Of the preliminary examinations, he strongly recommends the matriculation of the University of [illegible] being the most all-round in its subjects, and the portal through which the student may pass into almost any department of medicine, science, or art, should he so wish, at any future time. The regulation now in force at the Royal College of Surgeons of England requiring an apprenticeship he hopes will never be rescinded, for it is impossible that a thorough practical experience in dental mechanics can be gained at a dental hospital. He then passes on to the question of the desirability of taking the M.R.C.S. and L.R.C.P. in addition to the dental diploma, giving many apt examples of the value derived therefrom, and shows how this can easily be done by the moderately hard-working student.

SCARLET FEVER AT NEWQUAY.

THE chairman and medical officer of health of Newquay have written to *The Times*, pointing out that much has been done in recent years to improve the sanitary condition of Newquay, as much as £13,000 having been expended in the provision of a water-supply and of a drainage system for a population of less than 1700 persons. There has not been a single case of typhoid fever for the past five years, and the number of deaths from zymotic disease has been small; while the highest general death-rate during this period has not exceeded 14 in the 1000. The lesson to be learnt is, then, that the reputation of a summer resort for healthiness may be seriously damaged by the action of some of its inhabitants, who have allowed their supposed personal interests to prevent them from having due regard for the welfare of other people. It has repeatedly been shown that personal and public interests are really inseparable, and the punishment of Newquay will have a beneficial influence in checking similar misconduct in all parts of the country.

OVER-PRESSURE IN GLASGOW SCHOOLS.

THE Glasgow School Board would do well to pay some attention to certain remarks made by Dr. Robert Perry in his last annual report regarding the Dunoon Convalescent Seaside Homes, for which he is medical examining officer. Dr. Perry says that "among the children who were applicants for admission there was an increasing number who, although not convalescent from any acute disease, had had their health seriously impaired by overwork in school." This is pretty much in accordance with the experience of general practitioners, who often have occasion to see children, especially girls, suffering in the way indicated. The matter is plainly one which the School Board ought to investigate.

EELS IN WATER MAINS.

THERE appears to be some conflict between the East London Waterworks Company and the sanitary officers of the West Ham Local Board concerning the effects of the presence of eels in the mains of the company. The medical officer of health complains strongly of injury which he believes has been inflicted on the health of some of the inhabitants of his district, through their water-supply becoming polluted by the putrid matter from dead eels. The Water Company are disposed to attribute this illness to insanitary surroundings, conditions which are denied by the officers of the sanitary authority. But whatever the facts may be, there is no question that the drinking of water polluted in this manner is a sufficient cause of ill-health; and although there may be some reason for thinking that a specific disease like enteric fever may not be caused by it, it is quite possible that symptoms may be produced which would not be easily distinguished from those of that disease. It is some satisfaction to learn that there had only been seven cases of stoppage of mains from eels in the course of a fortnight in the water-

supply of over one million persons, but the action of the Company would inspire more confidence if they appeared to regard even this occurrence in a more serious light.

CHANGES AT THE LONDON HOSPITAL.

THE retirement of Sir Andrew Clark is an event for the London Hospital. It must bring to Sir Andrew much-needed time for the duties of his great practice, and so must have its conveniences. But those who best know Sir Andrew will be most ready to accord to him their sympathy in having to relinquish duties which have been so congenial and so faithfully discharged. Only a man of the rarest energy would have persisted so long in maintaining an appointment at the London Hospital while doing the work of such a large consulting practice as that enjoyed by Sir Andrew Clark. Mere strength does not explain such devotion. The enthusiasm of teaching and of learning is rather the explanation. We congratulate the hospital on having had such a physician, and we cannot doubt that it will still find means of retaining his interest and his services. We also congratulate the hospital on being able to fill up the vacancies caused by Sir Andrew's retirement. Dr. Stephen Mackenzie rises to the physicianship, and the assistant physicianship which he vacates is to be filled up by Dr. James Anderson, the present registrar of the hospital—two appointments which bode well for the future of the hospital, whether from the patients' or the pupils' point of view.

HYGIENE AND PUBLIC HEALTH.

THE University of Durham has resolved to grant a licence in Sanitary Science, and has thus recognised the increasing importance of this branch of medicine. Health officers have now to perform duties which require not only a knowledge of disease but of all the conditions which affect health, and they must, if these conditions are to be better understood, be trained to analyse the various circumstances which tend to shorten life. They must, moreover, in a manner, be lawyers, architects, and engineers, or, rather, they must be prepared to advise their authorities on the medical aspects of law, architecture, and engineering. For this purpose a special training is necessary, and the University of Durham has done well in following the example of other educational bodies in granting a certificate which bears witness to the fitness of the recipient to occupy responsible public health appointments. These qualifications are, we understand, in future to be registered.

SANITARY CONDITION OF WINDSOR.

DR. HUBERT AIRY, medical inspector, accompanied by Mr. Arnold Taylor, engineering inspector of the Local Government Board, opened an inquiry at Windsor on Tuesday last, into the sanitary condition of the Royal borough, the visit being made at the request of the local authorities.

SOLIDIFIED LINIMENTS.

ANYONE who has had to apply a liquid liniment to the chest, or any other part of the body in the upright position, will have experienced the difficulty in keeping the liniment in the palm of the hand until it is fairly brought in contact with the affected part. It is a matter of surprise that in the last edition of the Pharmacopœia liniments are retained in their liquid form. There is no difficulty in solidifying most liniments by the addition of some gelatinising material, so as to enable it to be smeared over the affected part with some approach to definitiveness of quantity and to the great convenience of the patient. Solidified liniments are not only more convenient of application, but are far more easy of transport. To the country practitioner this is a matter of considerable importance as well as to patients, for the introduction of the "parcel post" has transformed the means of transit of medicines; and to be enabled to send medicines in a solid rather than liquid form by post is a great advantage. Thus it is that pills for almost all forms of medicines are being purchased largely in place of draughts and mixtures, and solidified liniments, or, indeed, any forms of consolidated medicine, would be a real gain to both doctor and patient.

AN ELECTRIC SAFETY-LAMP FOR MINERS.

THE latest experiments with the electric light have resulted in the production by Mr. J. W. Swan of a portable miner's lamp, which is said to combine the light-giving and testing qualities which together constitute the essentials of a good safety-lamp for underground work. The light supplied by this instrument is of considerable brilliancy, and contrasts favourably in this respect with the comparatively dim flame of such oil lamps as are considered to be safe against explosions. The indicator used to detect the presence of fire-damp is sufficiently delicate to register the presence of a quarter to a half per cent. of this gas in the air of the mine. It is fixed to the lamp and consists in some cases of a coil of platinum wire, to which the electric current from the lamp battery is switched on as required, and which becomes hotter in a foul than a pure atmosphere. In other lamps the indicating wire is enclosed in a glass tube, and, when heated, decomposes the explosive gas in the form of watery vapour, the amount of which is the gauge of gaseous impurity.

TUBERCULAR INOCULATION IN A MAN.

DR. AXEL HOLST mentions the case of an attendant on the phthisical patients at a hospital who had suffered for a long time from atonic ulceration of the fingers, which had been treated with ointment, plaster, caustic, and scarification. No tubercle bacilli were to be observed with certainty in the sores. Later the man was affected with a tuberculous glandular swelling of considerable size in the axilla, which contained a considerable number of Koch's bacilli, and Dr. Axel Holst considers that it is highly probable the patient had received infection through the sores.

THE TYPHOID EPIDEMIC AT SWANSEA.

AT the meeting of the Swansea Town Council on Wednesday, the medical officer of health reported that during the past fortnight there had been 112 cases of enteric fever in the town. He called attention to the seriously defective condition of the drains, and said that the Camdon Kin reservoir had become polluted by the ingress of foul water from a neighbouring stream. The Council appointed a committee to undertake a thorough investigation. A proposal that the Local Government Board should be asked to hold an inquiry was negatived.

REGISTRATION FEES AT HOSPITALS.

AN attempt to impose a fee of one shilling on every out-patient at the Warneford Hospital has failed, though proposed by Lord Leigh and seconded by the Rev. Mr. Hallett. Much objection was raised to the proposal by the medical officers, Dr. Thursfield, ministers, and others. A letter from the Charity Organisation was read also objecting to the proposal, which was lost by a very large majority. The arguments against the proposal were that a registration officer would have to be paid, which would cost more than the registration fee would yield, and that by the propo[illegible]able character of the institu-

tion would be compromised. We concur in the objections. To charge a fee of one shilling at a hospital is to enter into a kind of commercial contract with patients, and a sort of commercial competition with practitioners. Let care be taken to exclude unfit recipients of hospital relief; but this done, let it be granted freely.

DR. FREDERIC FARRE.

WE are glad to learn that Dr. Farre, who has been suffering from pleurisy (not pneumonia, as stated in our issue of the 2nd inst.), is progressing towards recovery as favourably as can be expected, considering his great age—eighty-three.

THE nineteenth annual meeting of the Canadian Medical Association was held on the 18th and 19th of August, in Laval University, Quebec. The retiring president was Dr. Osler, of Philadelphia, who was unavoidably absent from the meeting. Dr. T. K. Holmes, of Chatham, Ontario, the new president, gave an address, in which he briefly reviewed the progress of medicine in modern times, and showed how future advances in the science must greatly depend on the kind and extent of the education imparted to the rising generation of medical men. A curious feature of this meeting, as of former assemblies of the Association, was, as our contemporary, the *Canadian Practitioner* remarks, the absence of the older men of the profession. Why is this?

A SOMEWHAT important communication was received by the Metropolitan Board of Works, at their last meeting, from the South Metropolitan Gas Company, calling attention to a danger to which the public are exposed, in consequence of builders removing subsoil from roadways and filling in the excavations with rubbish, with the result that settlements take place which cause injury to drains, gas and water-mains, &c. The letter was referred to a committee.

THE scarlet-fever epidemic at Wellingborough, which has prevailed since the last week in June, exhibits no sign of abatement. Mr. F. N. Heygate, medical officer of the Finedon District, in a letter to the *Wellingborough News*, expresses the opinion that, if due inquiry were made, it would be found that there were on the average three cases of the disease in each house.

THE President of the Medical Society of London, the first meeting of which will take place on Monday next, has issued a circular, in which he calls the attention of the Fellows to the "Clinical Evenings"—a recently introduced feature, to which it is intended to give effect on the last Monday of every month.

AT a meeting of the Executive Committee held at the Quebec Institute, Baker-street, W., on Wednesday last, to promote the candidature of Dr. B. W. Richardson for a seat on the Medical Council, Dr. Danford Thomas in the chair, it was announced that over 2000 members of the profession had already sent promises of support.

THE report of the sanitary condition of Linlithgow, as given by Mr. Falconer Stewart, inspector for the Board of Supervision, gives anything but a flattering account of the ass[illegible]ate of the burgh. The scavenging, drainage, and water-wh[illegible]pply all come in for more or less severe condemnation. "wa[illegible] exam[illegible]

[illegible]E Hygienic Museum, presided over by Dr. Koch, was higher[illegible] liminar[illegible]d at Berlin on Monday last. The collection is de-culation[illegible] as a very compr[illegible]

WE may direct attention to an advertisement in another column, in which the Secretaries of the Association of Members of the Royal College of Surgeons urge upon all Members of the College who have not yet signed the petition to Her Majesty in Council to do so without delay, and forward the copy thereof to the Secretaries, Western Dispensary, Westminster.

IT has been resolved to found a voluntary hospital for women who were formerly treated under the Contagious Diseases Acts. It is understood that, in the interest of soldiers and sailors, Government has determined to subscribe to the institution.

WE may remind our readers that the Harveian Oration will be delivered by Dr. Pavy on Monday next, at 4 P.M. The Oration will be published in our next issue.

THE measles epidemic at Bolton-by-Bolland is so extensive that it is stated there are but few children in the whole district who have escaped infection.

Pharmacology and Therapeutics.

JENSEN'S COD-LIVER OIL.

THE specimen which we have received of Jensen's medicinal cod-liver oil is of excellent quality. It is nearly colourless, has very little odour, and practically no taste. We are satisfied that exceptional care has been taken in its preparation, and that it will be found of much value in the treatment of phthisis and other wasting diseases.

HYPNOTIC PROPERTIES OF BOLDO-GLUCINE.

Dr. René Juranville of Paris has published as a graduation thesis an account of some experiments and observations on boldo-glucine, an aromatic substance of the nature of a glucoside, obtained by M. Chapoteaut from the leaves of the Pneumus boldus, or Boldo fragrans, a plant belonging to the Monimiaceæ, which has from time immemorial been employed by the natives of Bolivia, Chili, and Pern in hepatic diseases. The boldo-glucine used by M. Juranville is not the same substance as boldine, which is an alkaloid existing in very small quantity in the leaves, and was isolated in 1874 by MM. Cl. Verne and Boujol. The observations were directed to the hypnotic action of the glucoside, and were conducted on both animals and human subjects. Dogs were sent to sleep by intravenous injections of boldo-glucine, in quantities of from two to seven grammes. Observations were taken and curves constructed, showing that during the sleep produced the cardiac beats increased in rapidity, while the amplitude of the pulsations diminished; the arterial pressure was not affected. M. Juranville also gathered from his observations that anæmia of the brain was produced. His therapeutic researches were conducted on insane patients, the doses given being from 22·5 grains to 2 drachms, the substance being enclosed in gelatine capsules or introduced by means of enemata. It was not found easy to administer it in the form of draughts on account of their powerful odour. It gave rise to no disagreeable symptoms, and, indeed, appeared to stimulate the appetite and the digestive functions. The hypnotic effect was very definite, ten patients on whom it was tried being all sent to sleep, and in some cases their hallucinations being removed; the effect was not, however, permanent, the sleeplessness and hallucinations returning on the cessation of the treatment. M. Juranville concludes that though boldo is not a perfect hypnotic, it is likely to prove valuable in cases of neurotic or maniacal insomnia when other drugs have been tried without effect. Further study of its action is, of course, required before any very decided opinion as to its efficacy can be expressed.

PYRIDINE IN ASTHMA.

Pyridine is, according to the *Union Médicale*, valuable as an anti-asthmatic, whether the affection is of cardiac origin or otherwise. About a drachm of the drug is placed on a

plate in a small room, to which the patient pays periodical visits of from twenty to thirty minutes' duration three times a day. After two or three *séances* the râles in the chest disappear, the expectoration is more free, and sleep is obtained at night, or at all events relief from the asthmatic attacks. In some cases the improvement is permanent, in others it only lasts unimpaired for five or six days. Iodine treatment is then required, which is usually efficacious, but which cannot be borne by all patients.

QUININE AND OIL OF TURPENTINE IN MALIGNANT PUSTULE.

Dr. Don F. Rivas describes in *La Union de las Ciencias Médicas* some cases of malignant pustule which were rapidly cured by the application of a paste composed of quinine and oil of turpentine. One of the cases was that of a shepherd, in whose flock the disease had manifested itself. He was stung by a mosquito on the forehead, and two hours afterwards the head and neck were extremely œdematous. The paste was applied, and the pain and swelling shortly diminished. A couple of days later a large quantity of sanguinolent fluid was discharged, and by the fourth day the man was quite well. Another shepherd of the same flock, who was similarly affected, made use of some of his colleague's paste without consulting a doctor, and was also cured in four days. A third case was that of a woman who had a malignant pustule on the hand, which was unaffected by various remedies which were applied, but on the application of the quinine and turpentine paste the severe pain ceased almost immediately, and the œdema rapidly diminished, the patient being quite restored to health in four days' time.

LANTANINE.

Lantanine is an alkaloid discovered by M. Negrete, and extracted from Yerba sagrata of the family of verbenas. M. Buiza has observed that, like quinine, this alkaloid had some action on the circulation. It slows the nutrition, and at the same time lowers the temperature. The most delicate stomachs tolerate lantanine. Intermittent fevers that prove refractory to quinine have yielded to the influence of two grammes of lantanine. In order to produce antipyretic effects in febrile conditions the dose employed is from one to two grammes in twenty-four hours, given in pills of ten centigrammes. In intermittent fevers the drug is administered immediately after the paroxysm. Ninety-five times out of a hundred a further paroxysm will not appear. The tincture of latana cannot be employed owing to its intense bitterness, which cannot be masked by syrup or wine.

NAPHTHALINE IN URINARY DISEASES.

A naphthaline, which has been used to disinfect the stools, Dur[illegible] to the property of retarding the putrefaction of the [illegible] educa[illegible] and may therefore be administered for cases of urinary disorder in which the urine has a fetid odour. Daily doses of one gramme and a half of naphthaline in cases of pyelo-nephritis, cystitis, chronic prostatitis, and stricture with fistulæ, have rendered the urine sweet in from two to five days. The urine, from being turbid, purulent, and alkaline, becomes neutral or acid, and the quantity of pus is diminished. No disorder has been noted in the digestive processes. The drug does not augment the frequency of micturition.

IODOL IN EAR DISEASES.

Dr. Stretter, who has used iodol, the new inodorous substitute for iodoform, in a large number of cases of ear disease, finds that in acute purulent inflammatory affections iodol applications rapidly produce marked benefit, but that in chronic inflammations of the middle ear it is generally quite useless, or at best no better than other more common methods of treatment.

THE UNIVERSITIES OF OXFORD AND CAMBRIDGE.—A return moved for in the House of Commons by Mr. Harold Rogers has just been issued, containing the following particulars with regard to the Universities of Oxford and Cambridge:—(*a*) With respect to each University Professorship, University Readership, and University Lectureship; (*b*) with respect to the Fellowships of each College; (*c*) with respect to the number of students in each University; (*d*) with respect to the College and University statutes; (*e*) the amount and application of the common University Fund.

THE METROPOLITAN ASYLUMS BOARD.

THE Managers of this Board, at their meeting on Saturday, had under consideration two subjects of some importance. The first related to the visits of individual members of the hospital committees, which were formerly made to the institutions at other times than when the committees met. The Local Government Board had recognised the injury which resulted from this practice, and had interdicted it. The General Purposes Committee now proposed that each committee should nominate two members to visit their asylum, and this recommendation, after a warm discussion, was by a narrow majority adopted, the new members of the board mostly opposing it. It is unnecessary to comment upon the irregularities to which the former practice gave rise; that they occurred was sufficiently shown during the Homerton inquiry. If the Local Government Board should permit the wishes of the General Purposes Committee to be carried into effect, it is to be hoped that some regulations may be made as to the conduct of the managers selected for this purpose. Their first duty should be to visit the officer who is now held to be responsible for the general management of the institution, and who should be permitted to accompany them in their journey of inspection. The managers would in this manner have no difficulty in learning all details concerning administration, and there does not appear to be any reason why their visits, if made in a proper spirit, should be prejudicial to discipline.

The second subject, which was introduced by Sir Edmund Hay Currie, referred to the fact that but fourteen of the metropolitan sanitary authorities had consented to contract with the managers for the reception into their asylums of persons who were not paupers, and the recommendation was made by the General Purposes Committee that it should be intimated to the Local Government Board that nothing more could be done in the matter by the managers until Parliament had made it compulsory on the local boards to discharge their duties. The advantage which would accrue to the metropolis from this contract is not quite obvious; the difficulty of deciding whether the sufferer is a pauper or not makes it of the greatest importance that the duty of giving orders for the admission of patients should be in the hands of one authority, otherwise delay might be occasioned by the desire of the one body to throw the burden of expense on the other. After all, the expense would fall upon the district from which the patient came, and an amicable arrangement between the local sanitary and Poor-law authorities, by which the latter assist the former, is probably the best arrangement that can be made, until the whole question of the removal of infectious cases ceases to be related to Poor-law administration.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.

THE following notice has been issued by the Registrar of the University College of Medicine:—

The Senate has now instituted a new degree of Bachelor in Surgery (B.S.), the examination for which will be held together with that for the degree of Bachelor in Medicine, and will comprise, in addition to the surgical part of the examination for the degree of Bachelor in Medicine, a practical examination in Surgical Operations, and in the use of Surgical Instruments. Candidates must produce certificates of attendance on a course of Operative Surgery and on a course of Regional Anatomy, in addition to the certificates required for the degree of Bachelor in Medicine.

For the degree of Master in Surgery (M.S.) candidates must be of not less than twenty-four years of age, and must have obtained the degree of Bachelor in Surgery above named, and must have been engaged for a period of at least two years subsequently to the date of acquirement of that degree in attendance on the practice of a recognised hospital, or in the services or in medical or surgical practice. The subjects of examination will be Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, and Clinical Surgery.

The Senate has also instituted a Licence in Sanitary Science (L.S.Sc.), for which every candidate at the date of examination must be a registered medical practitioner.

must produce certificates of attendance on certain courses of instruction during a year of professional study at the University of Durham College of Medicine. It is not necessary that this year of professional study should be distinct from that required in the case of a candidate for the degree of Bachelor of Medicine. The examination will comprise Sanitary Chemistry and Physics, Sanitary Legislation, Vital Statistics, Meteorology with Climatology &c., Sanitary Medicine, and Practical Hygiene, and will be divided into written, practical, and *vivâ-voce* parts.

The following regulations are now in force as applying to candidates for the degree of Bachelor in Medicine:—Candidates who have completed part of their curriculum elsewhere may pass the first and second examinations previously to entering at Newcastle-upon-Tyne, and are recommended to commence their year of residence at Newcastle-upon-Tyne at the beginning of the winter session. Candidates will be admitted to each of these examinations after duly certified attendance at a recognised medical school on courses of instruction in the various subjects of the examination, as set forth in the Schedules of Certificates issued by the University. These may be obtained on application to the Registrar of the University of Durham College of Medicine. Each examination must be passed before the next can be proceeded with, and each must be passed in its entirety, except the First Examination, which may be taken in two parts at different times, one part comprising Elementary Anatomy and Elementary Physiology, and the other part of Chemistry with Chemical Physics, and Botany with Medical Botany. Failure in one of the subjects comprised in either part of this examination will entail rejection in that part. A candidate who has passed the First Examination of the Conjoint Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England will be exempt from the First Examination of the University of Durham except in the subjects of Chemistry with Chemical Physics, and Botany with Medical Botany, in which he will be examined. A candidate who has passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board in England, and will be entitled to present himself for the Final Examination of the Board on the completion of the necessary curriculum. Candidates who hold a qualification from a recognised licensing board in the United Kingdom at the date of entry for the First Examination for the degrees in Medicine are in every case required to pass in Chemistry with Chemical Physics; and are also required to pass in Botany with Medical Botany, if they have not previously passed in that subject at one or other of their examinations for qualification; but they are exempt from examination in Elementary Anatomy and Physiology. All candidates for the First Examination for the degrees in Medicine, whether exempt from a portion of it or not, are required to pay the full fee—£5.

The dates of the examinations will be as follows—viz.: The First Examination for the degree of Bachelor in Medicine will be commenced on April 18th, 1887, and again on Sept. 19th, 1887; the Second Examination will be commenced on April 25th, 1887, and again on Sept. 26th, 1887; the Third Examination will be commenced on Dec. 6th, 1886, and again on June 13th, 1887. The examination for the degree of Bachelor in Surgery will be commenced on the same date as the Third Examination for the degree of Bachelor in Medicine. The examination for the licence in Sanitary Science will be commenced on April 25th, 1887, and again on Sept. 26th, 1887.

THE NEW MEDICAL SESSION.

OWENS COLLEGE.

THE winter session of the medical department of Owens College was opened on the 4th inst. In place of the usual introductory lecture a conversazione was held in the medical school, Coupland-street, where the guests, who numbered about 400, were received by the Dean of the school, Professor W. H. Young. The whole of the rooms and departments of the school were thrown open, and visitors had an opportunity of inspecting the large and varied collection of objects in the medical museum. In the pharmacological laboratory Professor Leech gave demonstrations of the [illegible] of drugs on muscle, and a histological laboratory Professor Milnes [illegible] the methods of section-cutting and various forms of microtomes; and in the physiological lecture-room Professor Stirling dealt with the subject of models as aids in the teaching of physiology. Exhibitions and demonstrations of various kinds interesting to the medical student were given in other departments of the school, whilst excellent music was provided for the delectation of the company. In the course of the evening Professor Young read the annual report, from which it appeared that 323 students had attended the medical department during the session 1885-86—a number which exhibited a considerable increase over that of previous years, whilst the list of those who had been successful in passing the various professional examinations showed a corresponding extension. In the course of a subsequent address, the Professor, after reminding his hearers that the reputation of a medical school depended as much upon the character of its alumni as upon the quality of the teaching and the resources of the institution, referred to the amalgamation of the medical school with Owens College, and to the granting of a supplemental charter to the Victoria University, investing it with the right of conferring degrees in medicine and surgery. Experience alone, he said, could show them any weak points in their regulations for the granting of degrees, and perhaps modifications might be found necessary from time to time; but he thought he was justified in claiming for the College and the University the advantage of offering exceptional opportunities to medical students of acquiring a knowledge of their profession, and of obtaining the stamp of proficiency in the shape of a degree. He hoped also to see established before long a post-graduate course of instruction. After Professor Greenwood had offered a few observations to the students, Dr. Dreschfeld described the process of inoculation pursued by M. Pasteur as a protection against hydrophobia.

QUEEN'S COLLEGE, BIRMINGHAM.

SIR JAMES SAWYER distributed the prizes at this institution on the 1st inst., and at the conclusion of the ceremony remarked that in his opinion there were two distinct lines upon which the authorities of the institution must now look for advancement: one was upon the line of extension of external authority, and the other was upon the line of intrinsic development. He meant by the former that he should like to see facilities for graduation for the students of that school. He should like to see Queen's College associated with any other bodies with which it might act—to see it advancing to university standing. With regard to the other line of development, he thought, without waiting for this matter of university powers a single day, that they ought to set to work at once to make thier teaching as perfect as possible, and there was one way in which he believed this might be done. They ought, if possible, to develop the tutorial department of their teaching. Students who had some experience in medical education knew that a great deal hung upon this tutorial teaching as distinguished from the reading in their own rooms, or from professorial instruction. In every one of the subjects of the medical curriculum they had proper professorial teaching, but he should like to see both the tutorial and professorial combined, so that, for instance, they might have the professor of medicine and the tutor in medicine, and the same in surgery and midwifery.

ST. MARY'S PAST AND PRESENT STUDENTS' ANNUAL DINNER.

ON Friday evening the annual dinner of the past and present students of St. Mary's Hospital was held in the Royal Venetian Chamber, Holborn Restaurant. Mr. Edmund Owen, M.B., F.R.C.S., presided, and amongst his supporters were Sir Edward Sieveking, Col. Duncan, M.P., Surgeon-General Gordon, and Mr. G. P. Field, Dean of the Medical School, about 170 covers being laid.

After dinner the Chairman gave "The Queen" and "The Prince of Wales and the rest of the Royal Family," the toasts being accorded with musical honours. The Chairman also gave "The Army, Navy, and Reserve Forces," associating with the toast the names of Col. Duncan, R.A., C.B., M.P., Mr. J. Coleman Barr, and Surgeon-Commandant Cantlie, who responded in suitable terms. The Chairman next gave the toast of "Success to St. Mary's Hospital Medical School. To all St. Mary's men he would say that it

would be wise to pay them a visit once a year, or at least once in two years, or they would find their old *alma mater* grown out of all recognition. They had "annexed" another house in Westbourne-terrace as an addition to their residential college, and he hoped they would go on annexing. The Natural Science Scholarships originated by the late Dean, Dr. Cheadle, had attracted many to the school, and he could confidently say that the staff was never more unanimous, never more united, never more determined to do what was right for those under their charge. They now enjoyed exceptionally pleasant time, and their future was never so prophetic of prosperity. He hoped, however, that their glowing successes would not be the presage of decay. The toast was drunk with enthusiasm.

Mr. A. J. Pepper gave "The Past and Present Students of St. Mary's Hospital," which was responded to by Mr. H. Bullock, on behalf of the "Past," and by Mr. H. A. Kidd for the "Present."

Surgeon-General Gordon proposed "The Medical Staff and Lecturers," which was responded to by Sir Edward Sieveking, who spoke of the thirty-six years that he had been associated with St. Mary's, and hoped that the medical staff and lecturers would always pull well together in the future as they had done in the past. This was one of the reasons of their success. They had worked together as a family ought to work and live together. They had trusted one another. What was now being done was putting on the climax to the work of their predecessors. They were doing everything to encourage the healing art in the strict sense of the term.

Dr. W. B. Cheadle proposed "The Dean of the School," who, in responding, spoke of the good fellowship that existed between past and present students, and amid loud cheers announced an entry of over seventy students.

Dr. Stamford Felce proposed the toast of "The Orator of the Day."

Mr. Malcolm Morris briefly responded, and the toast of "The Chairman," proposed by Dr. Alfred Meadows, J.P., was drunk with musical honours.

During the evening songs were given by Mr. Bertram Thornton, Mr. Little, Mr. Lane, Mr. Critchett, Surgeon-Commandant Cantlie, and others.

WILLS OF MEDICAL MEN.

THE Scotch confirmation, under seal of office of the Commissariot of Ayrshire, of the will of John Findlay Arthur, M.D., C.S.I., Surgeon-Major, retired list, Madras Army, of Lochside House, New Cumnock, who died on July 26th last, granted to Mr. William Arthur, the brother, Mr. Robert Shankland, and Mr. David Mitchell Arthur, the nephew, the accepting executors nominate, was resealed in London on the 20th ult., the value of the personal estate in England and Scotland amounting to upwards of £28,000.

The will of Mr. John Archer, surgeon, late of 9, Carpenter-road, Edgbaston, Birmingham, who died on March 8th last, was proved at the Birmingham District Registry on Aug. 14th by Mr. George Frederick Bolding and Mr. Charles Augustus Harrison, the executors, the value of the personal estate amounting to over £23,000. The testator bequeaths legacies to his son, daughter, executors, nephews, nieces, coachman, and servants; and the residue of his real and personal estate he leaves upon trust as to one half for his son, William Gammon Archer, and as to the other half for his daughter, Mary Ellen Archer.

The will of Alfred Parr, M.D., late of Ravenleigh, Betchworth, Surrey, who died on June 19th last, was proved on Aug. 21st, by Mr. Alfred Harry Parr Ewer, the nephew, one of the executors, the value of the personal estate amounting to over £16,000. The testator gives an annuity of £100 to his said nephew during the life or widowhood of his wife; and there are some other legacies. The income of his residuary estate he leaves to his wife for life or widowhood, and at her death or marriage again his residuary estate is to go to his said nephew.

The will of Walter Moxon, M.D., late of Northolme, Broadlands, Highgate, and of 6, Finsbury-circus, who died on July 21st last, was proved on Aug. 13th by Mrs. Selina Moxon, the widow, the value of the personal estate exceeding £11,000. The testator states, "My last will is that all I possess shall be at the disposal of my wife after my death."

The will of Thomas Ross Jameson, M.D., Inspector-General, Army Hospitals, late of Lympstone, Devon, who died on July 6th last, was proved on Aug. 23rd by Mrs. Sarah Margaret Jameson, the widow, the value of the personal estate amounting to upwards of £10,000. The testator bequeaths £100 and his furniture and effects to his wife; and the residue of his real and personal estate is to be held upon trust for her for life. At his wife's death he gives an annuity to his sister, and the remainder of the income of his property is to be paid to his aunt, Mrs. Jane Carmichael, for her life. At her death he leaves two-thirds of the ultimate residue upon trust for his brother and sister, William Werner Jameson and Jane Milne Jameson; and one-third upon trust for his sister-in-law, Mrs. Eliza Ross Jameson, and her daughter.

The will and codicil of Christopher Joseph Madden, M.D., L.R.C.S.I., late of 12, Northwick-terrace, Maida-vale, who died on Aug. 8th last, were proved on Sept. 4th by Mr. Alfred Ransford and Mr. Robert James Miller, the executors, the value of the personal estate amounting to over £7000. The testator, after bequeathing a few legacies, gives the residue of his property to the Benevolent Society of Saint Patrick, Stamford-street, Blackfriars.

The will of Robert James Mann, M.D., late of 5, Kingsdown Villas, Wandsworth-common, who died on Aug. 4th last, was proved on the 3rd ult., by Mrs. Charlotte Elizabeth Mann, the widow, and Mr. James Sewell Neville, the executors, the value of the personal estate amounting to over £2000. The testator devises and bequeaths all the real and personal estate to which he shall be entitled at the time of his death to his wife for her sole and separate use absolutely.

The will of John Wills, M.D., of Pembroke-terrace, St. Helier, Jersey, who died on July 21st last, was proved in London on the 20th ult. by Mrs. Harriet Catherine Wills, the widow, one of the executors, the value of the personal estate within the jurisdiction of the English Court being over £900. The testator leaves all his property upon trust for the use of his wife for life; at her death there are annuities to Florence Maryon Burley and Eugenie Villais, and the ultimate residue is to go to his daughter, Mrs. Emily Rose Penton.

The following legacies have recently been left to hospitals and other medical charities:—Mr. Richard Howard, of 2, Shirley Villas, Addiscombe-road, Croydon, £250 each to the Hospital for Sick Children, Great Ormond-street, the London Hospital, the Royal Hospital for Incurables, Putney, and the Croydon General Hospital.—The Rev. William Henry Edmeades, of Nurstead Court, Kent, £100 to the Gravesend Dispensary or Hospital; and £50 each to the Brompton Hospital for Consumption and the Hospital for Incurables.—Miss Mary Elizabeth Tanner, of Foulden Lodge, Upper Clapton, £3000 to the Hospital for Incurables, Putney, £500 to the German Hospital, Dalston, and £100 to the Dispensary at Stoke Newington.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5691 births and 3369 deaths were registered during the week ending Oct. 9th. The annual death-rate in these towns, which had declined in the preceding four weeks from 22·6 to 20·6, further fell last week to 19·3. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·4 per 1000, and was 0·8 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 14·2 in Bristol, 15·7 in Brighton, 17·2 in London, and 17·5 in Birmingham. The rates in the other towns ranged upwards to 23·9 in Newcastle-upon-Tyne, 24·4 in Bolton, 25·4 in Liverpool, and 29·9 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding four weeks from 1202 to 746, further fell last week to 578; they included 324 from diarrhœa, 70 from "fever" (principally enteric), 70 from scarlet fever, 42 from measles, 42 from diphtheria, 30 from whooping-cough, and not one from small-pox. The lowest death-rate from these zymotic diseases were recorded last week in Huddersfield, [illegible] and Cardiff; and the highest in P[illegible]-Tyne, and Y[illegible]

hampton. Diarrhœa caused the highest death-rates in Norwich, Preston, Sunderland, and Wolverhampton; "fever" in Preston, Halifax, Norwich, Derby, and Portsmouth; scarlet fever in Liverpool and Salford; measles in Wolverhampton and Halifax; and whooping-cough in Preston. The 42 deaths from diphtheria included 28 in London, 4 in Portsmouth, 4 in Liverpool, and 2 in Leeds. Small-pox caused no death in London and its outer ring, or in the twenty-seven large provincial towns; and only one small-pox case was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding four weeks from 110 to 187, further rose last week to 229, but were 26 below the corrected average. The causes of 72, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leeds, Leicester, and in seven other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Sheffield, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·8 and 18·3 per 1000 in the preceding two weeks, further rose to 19·8 in the week ending Oct. 9th; this rate was, however, 0·5 above the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 8·3 in Greenock and 13·5 in Aberdeen, to 24·6 in Perth and 27·8 in Paisley. The 489 deaths in the eight towns last week showed a further increase of 37 upon the numbers in the previous two weeks, and included 25 which were referred to whooping-cough, 22 to diarrhœa, 21 to scarlet fever, 6 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 3 to measles, and not one to small-pox; in all, 82 deaths resulted from these principal zymotic diseases, against 78 and 63 in the previous two weeks. These 82 deaths were equal to an annual rate of 3·3 per 1000, which corresponded with the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had declined in the previous four weeks from 57 to 34, further fell last week to 22, of which 8 occurred in Glasgow, 4 in Edinburgh, and 3 in Dundee. The mortality from diarrhœa in the Scotch towns last week was again considerably below that which prevailed in the English towns. The 25 fatal cases of whooping-cough showed a considerable increase upon the numbers in recent weeks, and included 20 in Glasgow and 3 in Paisley. The deaths from scarlet fever, which had been 9 and 8 in the previous two weeks, rose last week to 21, of which 14 occurred in Glasgow, 4 in Dundee, and 2 in Paisley. Of the 6 deaths referred to "fever," 2 were returned in Glasgow and 2 in Paisley. The 5 fatal cases of diphtheria included 3, and the 3 of measles 2, in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 65 and 67 in the previous two weeks, further rose last week to 93, and exceeded the number in the corresponding week of last year by 29. The causes of 73, or nearly 15 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had declined in the preceding three weeks from 27·5 to 22·8, was 23·1 in the week ending Oct. 9th. During the thirteen weeks of the last quarter the death-rate in the city averaged 22·1; the mean rate during the same period was 18·7 in London and 17·5 in Edinburgh. The 156 deaths in Dublin last week showed a decline of 2 from the number in the previous week, and included 17 which were referred to diarrhœa, 6 to scarlet fever, 4 to "fever," 1 to whooping-cough, and not one either to small-pox, measles, or diphtheria. Thus 28 deaths resulted from the principal zymotic diseases, against numbers ranging from 29 to 30 in the preceding four weeks; they were equal to an annual rate of 4·1 per 1000, the rates from the same diseases last week being 2·1 in London and 1·6 in Edinburgh. The fatal cases of diarrhœa, which had been 29, 25, and 23 in the preceding three weeks, further fell last week to 17. The 6 deaths from scarlet fever showed a decline of 2, while the 4 from "fever" exceeded the number in the previous week by 2. Six inquest and 7 deaths from violence were registered; and 31, five-fifth of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a decline from the numbers in recent weeks. The causes of 19, or more than 12 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-Major E. Farrington Boult has retired upon temporary half-pay.

ADMIRALTY.—The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet: Arthur Willoughby Russell and William Edwards Breton.

The following appointments have been made:—Staff Surgeon A. W. Russell, to the *Hyacinth*, reappointed on promotion; Staff Surgeon W. E. Breton, to the *Kingfisher*, reappointed on promotion; and Surgeon W. Lindsay Chubb, to be Surgeon and Agent at Sandgate.

ARTILLERY VOLUNTEERS.—1st Cheshire and Carnarvonshire: Arthur John Jefferson, Gent., M.B., to be Acting Surgeon.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Royal Warwickshire Regiment: Acting Surgeon George Wilson resigns his appointment.

Correspondence.

"Audi alteram partem."

HOSPITAL FOR WOMEN, LIVERPOOL.

To the Editor of THE LANCET.

SIR,—I beg to enclose copy of correspondence between the honorary secretary of the Hospital for Women, Liverpool, and Sir Spencer Wells, Bart. With Sir Spencer's permission, I ask the favour of its insertion in your forthcoming number, as I think it will be of interest to your readers at the present time.

I am, Sir, yours truly,

Oct. 11th, 1886. THOMAS F. GRIMSDALE.

3, Upper Grosvenor-street, London, W., Oct. 4th, 1886.

DEAR DR. GRIMSDALE,—The honorary secretary of the hospital of which you are the consulting physician has sent me a letter which I think it right to forward to you, with a copy of my reply. I ought to have added that the inquiry I propose should include the question whether the operation was performed after consultation or not. I have only alluded in my letter to the honorary secretary to the 111 cases where abdominal section involved partial or complete "spaying." If I had included all the cases of abdominal section, there would have been 160 out of 347, adding greatly to the force of the argument in favour of a full inquiry. You are quite at liberty to make any use you please of this correspondence. Yours very truly,

T. SPENCER WELLS.

Hospital for Women, 107 and 109, Shaw-street, Liverpool, Sept. 21th, 1886.

SIR,—A question having been raised regarding the practice of our institution, my committee would thank you for an expression of opinion on the cases treated in 1885, a detailed account of which is contained in the annual report which I have taken the liberty of sending to you to-day. The question raised refers chiefly to the operations of removals of uterine appendages, of which there have been in 1885 96 total removals, and 15 partial removals. The opinion has been expressed here—probably not unbiased by specific local influences—that this was excessive. The committee, wishing to arrive at a perfectly impartial appreciation, would much value your opinion on the subject. The committee would call attention to Table II. on pages 16 and 17 of the report, and to Table III., pages 18 to 33, the former giving the summary of in-patients, the latter particularising each individual case; also to page 10, giving a statement of the total annual work of the hospital, from which you will see that the total number of patients, counting in- and out-patients, amounted in 1885 to 3858, of whom 347 were in-patients and 3511 dispensary patients. Now it would appear that out of so large a total as 3858 patients

the number of 96 total removals of uterine appendages and 15 partial is *not* an excessive figure, but a very moderate one, bearing in mind that many cases of the worst kind were sent into hospital by practitioners outside, who have not the opportunity and facility of treating them found at our hospital. These 96 and 15 cases would therefore appear to be drawn not only from 3858 hospital patients proper, but from a much larger area, comprising the practice of many of the 300 medical men in Liverpool. Many patients also come from Wales and other towns in Lancashire, even from Canada; and a computation has been made by a medical man unconnected with our hospital that out of so large an area 600 annual cases of that kind would not be excessive. The 96 and 15 cases referred to would therefore appear to imply a very careful selection of the most urgent only for operation. It must be here stated that there are 33 beds at our hospital, and, besides these, there are none for the treatment of these cases in Liverpool, except the 17 beds in the Thornton ward of the Royal Infirmary, so that naturally the vast majority of cases aggregate at our hospital. The committees beg to tender you their thanks for any expression of opinion which you may make on the subject, and which will be invaluable to them.

I remain, Sir, your most obedient servant,
F. C. A. MINOPRIO,
Hon. Sec., Hospital for Women, Shaw-street, Liverpool.

Sir T. Spencer Wells, Bart.,
Samaritan Hospital for Women, London.

Balmaboth, Kirriemuir, September 29th.

DEAR SIR,—Your letter of the 24th inst. has been forwarded to me here. In reply I feel bound to say that as the total number of in-patients in the Hospital in 1885 was only 347, the statement that of these 111 (or nearly one-third) were subjected to abdominal section is so shocking as to be almost incredible. If it is correct, in my opinion a most complete and searching inquiry should be made into the details of the case of every woman operated upon; the reasons why the operation was performed; whether it was done after full explanation of the danger and of the necessary results to the patient and her husband; and what has been gained or lost by each woman who has survived the operation.

I am, dear Sir, yours truly,
To the Hon. Secretary, Hospital for Women, Liverpool. T. SPENCER WELLS.

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—It is not desirable that controversy on this subject should be further embittered. I, for one, will only ask you for a few lines in reply on *two* points only, and I trust to your courtesy and sense of fair play to give them insertion in your next issue. Indeed, the present crisis is too important, too pregnant with the well- or ill-being of our common profession, to make it a time for controversial recrimination. It is a time rather when all of us should unite in the single effort to secure three good men to represent us on the Medical Council. Whether these men be consultants or general practitioners, or both, or nominated by one or other committee, matters nothing; but it does matter that they should know the educational and other wants of the general practitioner, and be able to make those wants heard and respected at headquarters.

With this preface I will proceed to remark upon the two points to which I wish to call the attention of your readers. The first is the alleged want of *freedom of action* in this matter. Will anyone point out in what way the freedom of the electors is interfered with, or can be interfered with, by our committee? Each elector will sign his voting-paper in the privacy of his own consulting-room. It will be a ballot, in fact, no one except the returning-officer necessarily knowing how anyone has voted. In every election voters are plied with addresses, cards for promises, and all the artillery of persuasion. What of it? The ballot gives us full protection from any interference with our freedom, and each of us can afford to throw all those paper bullets of which we do not approve into the waste-paper basket. Then, as to pressure. Again I will ask, in what consists the difference between the pressure exerted by *one* committee for *one* man, and that of a committee which recommends three men? As to numbers, I find one candidate has a committee of not less than six hundred working for him; whilst ours has only four hundred. Surely the *pressure* here must be in the proportion of six to four! And this leads me to explain a point which is perplexing many as to the action of our committee. Our committee was instituted to select *three* fit and proper persons by what was, in effect, a ballot. It is by no means the desire of that committee to compel those who agree with their general principle to vote for all those three candidates *en bloc*. Many are pledged already to some other candidate, and all we ask is, that the profession at large will well consider the claims of Messrs. Wheelhouse, Foster, and Glover, and vote for such of them as they may feel at liberty to do.

Now to my second point: Although in Dr. Glover's courteous letter to me, which appears in the last number of THE LANCET, there is no mention of *caucus* or *clique*, these terms are still used by others in their addresses, and by the members of their committees, and they are applied to the "Birmingham" committee only. Now it has been already fully explained that our committee was formed *absolutely* without reference to any particular persons to be recommended. Over 1000 members of the profession were asked to form a committee, and of the 360 who responded nothing was known of their sentiments with regard to *any* candidate. Therefore, whichever three persons had obtained the largest number of votes, those three persons must have been adopted by the committee. Is this a *caucus*? and is it possible to call 360 gentlemen scattered all over the country, few of them having any personal knowledge of each other, a *clique*? So absurd do these accusations appear to us here that we consider it would be a waste of time to take further notice of them.

Before concluding, I would like to caution voters against forming too high an estimation of the powers conferred by the Medical Act upon our direct representatives. Too great expectations will, I fear, only lead to disappointment. From the numerous letters you have published, and from the tenour of the addresses of some candidates, we might be led to expect the regeneration of the profession itself from the efforts of these gentlemen. But it must be remembered that the General Medical Council has authority only over education and registration. It may raise the standard of education, it may look sharply after the licensing and examining boards, and it may punish criminal persons by removing their names from the Register; but I do not see how it can deal with club or union practice, or interfere with quacks or unlicensed persons. These points require further legislation.

I am, Sir, yours faithfully,
Worcester, Oct. 13th, 1886. WILLIAM STRANGE, M.D.

TREATMENT BY MASSAGE.

To the Editor of THE LANCET.

SIR, The letter on Treatment by Massage by Dr. Sturges, senior physician to the Westminster Hospital, is of considerable interest, as affording an admirable example of the necessity which still exists for elementary instruction in the subject. Dr. Sturges falls into the curious error of confounding massage with the Weir Mitchell treatment. Everyone who has the slightest acquaintance with the literature of massage knows that Dr. Weir Mitchell was not its "original proposer," and I am sure that distinguished neurologist would be the first to repudiate any claim to be considered an authority on the subject. Dr. Weir Mitchell's paper on "Rest in the Treatment of Nervous Diseases" appeared originally, in 1875, in Seguin's Series of American Clinical Lectures long after the publication of Dr. Mezger's classical thesis, and the works of his pupils Berghman and Helleday, and of Phélippeaux, Gautier, Estradère, Laisné, and a host of other writers. In Weir Mitchell's "Gunshot Wounds and other Injuries of the Nerves" (1864), the word massage is not even mentioned, and there is but a passing reference to the value of shampooing; whilst in the first edition of "Fat and Blood" (1874), the author distinctly disclaims any thought of "putting forth anything very remarkable or original," and states explicitly and with commendable candour that the different procedures which, taken collectively, constitute his method have been employed individually, one and all, by other physicians. Dr. Douglas Graham of Boston, who, in the opinion of Dr. Benjamin Lee, unites in a greater degree than anyone in America the [illegible] skill of an accomplished

masseur with the theoretical knowledge of an intelligent educated physician, says: "Not a few of the profession applaud Dr. Mitchell and Professor Playfair in a manner that would lead us to infer that they are to be considered the original inventors of massage, and give their whole sole and exclusive attention to it and the cases in which it is useful. With equal propriety might they be regarded as experts in chemistry and materia medica because they use medicine as well as massage, or specialists in electricity because they have called largely on this medical agent to assist them." Shampooing or medical rubbing, which is very useful in its way, can readily be acquired by anyone "in a few lessons," but the true massage, as practised by Professor Von Mosengeil and others on the Continent, depending as it does on a knowledge of anatomy and physiology, certainly cannot be mastered in less than two years.

I am, Sir, your obedient servant,

Weymouth-street, W., Oct. 11th, 1886. WM. MURRELL, M.D.

To the Editor of THE LANCET.

SIR,—Having had some considerable experience in the practice of massage and manual treatment, I beg to protest against the statement by Dr. Sturges in last week's edition that the system can be acquired in a few lessons. The argument used by Dr. Sturges is curious. If it takes "two years" to learn, "why not ten"? he says. So one may ask, if it takes four years to make a surgeon, why not forty? Again, he says: "It may be confidently asserted that there is no digital use whatever needing two years for its acquirement that does not go on advancing towards perfection so long as the mind which informs the fingers retains its vigour." Grant all this. The masseur does become more perfect through years of work; but the point is, how soon is he able to practise the art with benefit to the patient? This question he answers by saying it is a knack, and is acquired, like lawn-tennis or cricket, "in a week." Now, doubtless many are quicker at acquiring it than others; but the benefit the patient can derive must be in proportion to the skill shown, and it seems utterly unreasonable that a method of treatment which requires delicate manipulations of different kinds, and a considerable knowledge of physiology and anatomy, can be sufficiently acquired in a week. Much harm undoubtedly is often done by inexperienced operators. I do not refer especially to the method employed by Dr. Weir Mitchell, and described in his little book entitled "Fat and Blood," but to the whole practice of mechanical treatment, which, though it has existed in rude form for ages, yet really came into prominence and assumed scientific form at the beginning of the present century, when Ling introduced his system at the University of Lund. The methods of Drs. Weir Mitchell and Playfair apply only to a limited range of cases, and consequently the manipulations are limited; yet, even in cases where those limited manipulations were to be applied, I, for my part, should prefer a nurse who had much more experience and practice than could be obtained in a week, precisely on the same ground as when Dr. Sturges administers a drug he would prefer a good one.

The whole system of massage or manual treatment is of very much wider area than that covered by Dr. Weir Mitchell's method. In Sweden, the home of the treatment, it has been employed for many years and for many diseases with admirable results. The Central-Gymnastik Institut (founded by Ling) still flourishes in Stockholm, and furnishes a thorough education in all the manipulations wrought out by Ling and improved upon by his successors. In addition to the practice of the manipulations, physiology and anatomy are carefully taught, and at the end of a two-years' course a diploma is granted by the Institut. Men from that institution are now practising all over Europe, and it is certain that in the struggle between the trained and the untrained there can be only one issue. Why should we not have a similar institute in London, where a system could be taught and properly equipped manipulators sent into the field? If the treatment is to be carried out at all, why not be thorough? If, as Dr. Sturges admits, it is a treatment which "confessedly needs skill, dexterity, and practice," can anyone believe that a few lessons can do this? No; if the "settling day" has to come "when its precise value will be finally determined," that can only be when we have careful observers and trained [illegible]. Without these the settling day will be deferred for ages, or the practice itself will fall into the region of empiricism and quackery.

I am, Sir, yours truly,

Stranraer, N.B., Oct. 1886. THOMAS EASTON, M.A., M.B.

INDUCTION OF PREMATURE LABOUR IN CERTAIN SEVERE CASES OF ALBUMINURIA.

To the Editor of THE LANCET.

SIR,—The publication of Professor Cullingworth's case in last week's issue of the "successful induction of premature labour in an extreme case of albuminuria" induces me to place on record a similar case with somewhat similar treatment.

Mrs. S——, primipara, aged twenty-six, came under my care on Nov. 5th of last year. The case on examination proved to be one of pregnancy complicated with albuminuria. The confinement was expected about the middle of January of the present year, thus making her period of pregnancy somewhat less than seven months. The lower extremities were extremely anasarcous, the hands and face slightly so. The quantity of urine passed was much less than natural, was of high specific gravity, and highly albuminous, containing a large quantity of casts—hyaline and blood casts. The treatment consisted of diaphoretics, the hot-air bath, free purgation, and free leeching of the loins. Notwithstanding this, the urine gradually diminished and became more albuminous, until, on the 27th instant, the quantity passed in the previous twenty-four hours only reached between three and four ounces. Now came intense headache, impaired vision, vomiting, and a condition highly suggestive of uræmia. Under these circumstances, with no labour imminent, I considered the best treatment would be to induce premature labour. This I did in the usual manner with a gum-elastic catheter, and with the best results, as my patient was delivered within twenty-four hours from the introduction of the catheter of a living female child, apparently about seven months' gestation. The after progress was all that could be desired; the urine was passed in large quantities, and within one week was quite free from albumen. I am Sir, yours truly,

Bolton, Sept. 1886. ROBERT PATRICK, M.D.

To the Editor of THE LANCET.

SIR,—It seems to me that Dr. Cullingworth's judicious treatment of his patient by hydragogue cathartics and hot-air baths played a more important part in the prevention of convulsions than did the cheerful disposition of the patient, and he has every reason to be satisfied with so favourable a termination of such a serious case; but I would submit that it is not fair to judge of the effect of pilocarpine in the albuminuria of pregnancy from the result of this case, for, to quote the words of the report, "it produced no result whatever," and therefore as the characteristic diaphoresis did not ensue, it is evident the pilocarpine was inert, and as it was given in a sufficiently large dose—a third of a grain—it is fair to assume it was the fault of the particular specimen used. I am, Sir, yours &c.,

Sunderland, Sept. 18th, 1886. JAMES MURPHY.

"INFANT FEEDING."

To the Editor of THE LANCET.

SIR,—I hope space may be granted me for a short letter in answer to that of Dr. Thurstan, published in your issue of Oct. 9th.

I am quite unable to accept his interpretation of the value of a physiological basis for our actions in dietetics or, by inference, in any branch of medical treatment. Such knowledge has governed me in coming to the conclusions I have, and has made, I trust, my experience of ten years children's work of more value than it would have been without such help. The question that we are discussing is, I gather, that of *hand-rearing* of infants from *birth*, and not when affected by diarrhœa or some such ailment. My remarks, I would say, must be accepted as within this belief. My experience is entirely opposed to Dr. Thurstan's assertions, having been built up after duly testing methods such as he advocates. I am prepared to state that in conjunction with the general measures referred to in my

note, and which want of space will not allow me to give in detail, a cow's-milk diet or some modification of it will succeed admirably. What I wished to convey by my first letter was that the question of "infant feeding" in his paper, as in very many others, is dealt with in a narrow and incomplete way. Failure with cow's milk, as before said (and this statement is based absolutely on personal experience both in hospital and private work), too often occurs from the manner of using it. Intolerance of it is acquired by too frequent feeding, too large meals, too rapid feeding, or too strong a mixture. Dr. Thurstan's letter makes clear to me that this aspect of the question has not sufficiently engaged his attention, hence his failure. In support of this statement, I would remind him that even in his letter the *times* of feeding are not very definitely stated, and the *quantity* for each meal is not given. Another practical point not referred to, I believe, in any handbook on the subject is that milk varies very much in strength at different times of the year. For instance, in May greater caution has to be used in increasing the strength of the meals than would be practised in October or later. The reasons for this will be obvious to most people. His precaution as to the care of the bottles and tubes is certainly not the best method. In the first place, tubes are not advisable, and in the second, water alone will not keep either the bottle or the tube chemically clean. For more on this head, and, indeed, for much useful, general and special information, he will, I hope, permit me to refer him to my friend, Dr. Goodhart's "Student's Manual on Children." In this work he will find a suggestion of mine as to the value of a solution of salicylate of soda for keeping bottles, &c., pure. I must admit that with farinaceous feeding an increase in the bulk of the infant is speedily obtained, but I also know that health in the future is risked by this practice. Children fed in this way declare their weakness usually about the end of the first year. The oft-repeated advice that one cow's milk should be used is also endorsed by Dr. Thurstan. I would suggest that the milk from one *dairy* be used. By so doing a product is obtained the result of a method of feeding common to many cows, and in this way the disturbing influences of menstruation, which occurs regularly in this animal, even when giving milk, are avoided. Other possibly injurious factors are reduced in importance.

Sufficient has been said, I hope, in this letter, to show that my chief motive for writing has been to point out what I believe to be the much too common error of dealing with infant feeding, as if the selection of food alone was to give us all we want—viz., health and comfort to babies.

The interest which I take in the subject must be my excuse if I have appeared dogmatic.

I am, Sir, your obedient servant,

LEWIS W. MARSHALL, M.D.,
October, 1886. Hon. Surgeon, Children's Hosp., Nottingham.

NON-RECOGNITION OF PROFESSIONAL WORK IN THE ARMY MEDICAL DEPARTMENT.

To the Editor of THE LANCET.

SIR,—I venture to think that the article in THE LANCET of Sept. 25th, directing attention to the above as "a serious defect" in its administration, will strike a chord and throw a ray of light and hope in many a hard-working and willing, but disappointed, member of this branch of the public service. The main reason for the existence of the medical staff is unquestionably professional, and yet this is the one aspect of it that lacks encouragement from those in authority. We have in our ranks men who, by their contributions to service generally, and to medicine especially, by taking the higher degrees of the colleges to which they belong, by qualifying for sanitary degrees, by filling educational posts in the Netley School without pecuniary increase, by filling important posts in general and special hospitals requiring special talents, by work during epidemics and in the no less important but quieter paths of every-day duty, have proved beyond all doubt their capacity, love of work, willingness and desire to further as far as in them lies the good of the State they serve; and yet where is the man in the present Army List who has received the slightest recognition by advancement or reward as a stimulus to himself or others towards professional culture? Selection has been the keynote to several warrants, and one of the objects in instituting the examination for promotion to brigade rank was to furnish the means to this end. Yet even here, in no instance has the strict line of seniority been departed from; exclusion merely has been increased in frequency. We are all aware that the present scheme of the department is not acceptable to the military authorities who control promotion and rewards, equally as that to produce good work in it and progress requires the bringing to the front the most competent. Yet what more potent means can be devised to obstruct improvement and oppose the normal development, to produce a dead level of professional mediocrity, than the present system of advancement by length of service and rewards controlled by the military chief? If the State requires that the medical staff of its army should be a body capable of efficiently and thoroughly carrying out professional and sanitary work, both in the administrative and executive ranks, let it take care that warrants be not ignored, that selection be the rule, that wholesome stimulants to self-culture be forthcoming, and that the responsibility and source of advancement be centred in the man most capable of exercising it—the medical head. We are not "the sweepings of the schools," as stated in the House of Commons; we are fair representatives of the profession as a whole; while deprived of the competitive struggle and outside influences towards progress existent in civil life, we are very human, and respond to the stimulus of recompense or sink into lethargy through neglect, as other men. What we want as a body is to be freed from certain impediments to our work, and as individuals to find honourable recognition by promotion and rewards of honest labour and professional culture; and these granted we will give a good account of the power and duties entrusted to us by our employers.

I am, Sir, yours truly,

Sept. 4th, 1886. ONE OF THEM.

THE PROPOSED NEW MEDICAL DEGREE.

To the Editor of THE LANCET.

SIR, I do not gather from the correspondence in the medical journals on the subject of the proposed new medical degree whether any provision is contemplated for the admission to the degree without further examination of men who are already Fellows of the Royal College of Surgeons of England or Members of the Royal College of Physicians of London; but I cannot help thinking that if this proposal were fairly considered it would receive the support of the "powers that be." It must be remembered that before the University of Durham made their present liberal provision for practitioners of fifteen years' standing, some men in practice, moved by a laudable desire to possess a higher qualification than that which they had obtained at the close of their career as students, passed the examination for one or other of the above-mentioned distinctions; and some have done so who, having been *less* than fifteen years in practice, were not at the time eligible for the Durham degree. Now, I think it will be admitted by all that a man who has obtained the *superior* qualification of either of the two London Colleges must be, from a professional point of view, more completely trained and educated than the ordinary run of men, and might therefore most appropriately be admitted at once to the new Doctorate, without being subjected to the annoyance of any further examinational test; perhaps even the University of Durham itself, if this matter were laid before the Senate in a proper light, might be willing to concede that the incorporation among their own graduates of the few men who might desire admission from among those to whom my remarks refer would not be likely in any way to damage the prestige of their degree, while those who were so incorporated could hardly fail to derive much gratification from being thus recognised by and connected with one of the great educational centres of the kingdom.

I am, sure, Sir, that the expression of your opinion on these points, and the assistance of your pen, would be very welcome to some of my professional brethren; and doubly so if it should be the means of bringing about a decision favourable to my suggestion. Hoping that others will take this question up, I am, Sir, yours obediently,

Sept. 27th, 1886. BETA.

NEW VICTORIA HOSPITAL.—On Wednesday this hospital, situated in Burnley, was opened by Prince Albert Victor, in the presence of a distinguished company.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE COLLEGE OF MEDICINE.

THE inaugural meeting in connexion with the re-opening of the College of Medicine here took place on Tuesday, Oct. 5th. In the absence of the President of the Council, Dr. Heath, Dr. Gibson took the chair. The preliminary proceedings were of the usual formal character, including the presentation of prizes to successful students, which office was gracefully undertaken by the Mayor of Newcastle, B. C. Browne, Esq. In his address to the students, the Mayor, in reference to preventive medicine, pointed out that the time might come when this would be the most important part of their work, and arrangement might be made for the payment of medical men out of the rates for this purpose. He thought also that, considering the shortness of human life, the active period of life might be prolonged and suffering abridged were medical men called in sooner and oftener in cases of illness. Altogether the Mayor's address was an advanced one, suggestive and pithy, and would have a good tendency as regards his hearers and the public.

SUNDERLAND HOSPITALS.

At a public meeting held last Tuesday, in Sunderland, to appoint a committee to carry out the proposed extension of the infirmary as a memorial to the late Alderman Hartley, it was mentioned that the proposal to amalgamate the Children's Hospital with the Sunderland Infirmary had been favourably considered by a committee of both institutions, and was now in a fair way of being accomplished. It was also stated that the proposed amalgamation had given satisfaction to all classes in the town, and that it would tend largely to the benefit of the sick poor. On Thursday last an election took place of a physician to fill the honorary post vacant by the resignation of Dr. Dixon, who has for many years acted as physician to the Sunderland Infirmary. Dr. A. B. Low was elected out of many candidates. This, I believe, is the first time that the new system of providing for such vacancies by an election committee chosen from the governors was adopted. The voting was by ballot, canvassing also having been abolished.

VACANCIES AND CHANGES IN NEWCASTLE HOSPITALS.

By the resignation of Dr. Houseman the post of physician to the Children's Hospital has become vacant; and in view of the prominent position likely to be taken by this charity amongst our institutions—the new building due to the munificence of Mr. Fleming being about to be erected—the post appears to be a desirable acquisition to our younger practitioners. The following gentlemen are already in the field: Drs. Beatley, Robertson, Baumgartner, and Blair. Owing to the resignation of Dr. Heath, a vacancy has taken place in the Newcastle Eye Infirmary in the office of surgeon in ordinary. Dr. Heath's services to the institution for many years have been invaluable, and it is to be hoped that the governors of this old and useful charity may be fortunate in finding a worthy successor. Dr. William Robertson has succeeded Dr. Houseman as assistant-surgeon at the Newcastle Throat and Ear Hospital.

NEWCASTLE INFIRMARY.

The *Evening Chronicle* refers to the critical financial position of the Newcastle Infirmary, and says that, as a result of a meeting held on Thursday last, a special appeal is about to be issued by the committee of the infirmary for increased pecuniary aid on behalf of the institution. The circular will intimate that unless the public will contribute more liberally, it will be necessary to close certain wards and adopt a policy of retrenchment. This would be a serious calamity to the town and neighbourhood, especially at the present season, when so much sickness is prevalent.

Newcastle-on-Tyne, Oct. 9th.

EDINBURGH.

(From our own Correspondent.)

POST-GRADUATE MEDICAL COURSE.

Now that the last week of this autumn session has arrived, a glance at the work accomplished in the special courses for medical men gives the impression that the experiment has proved a [illegible] success. Both as regards the numbers attending—over 100 in all—and as regards the technical value of the demonstrations themselves, little is left to be desired. There has been throughout clear evidence of the keen interest felt by the graduates attending the course, and on the part of the teachers no less must be said, in looking to the comprehensive nature of the instruction they have given. There has been but little in the way of systematic or theoretical teaching, and that little has been strictly confined to commentaries upon cases exhibited; whilst the clinical and practical methods of demonstration have been fully developed; so that in returning to their homes our visitors will not so much be burdened with an added weight of abstract conclusions, as they will be impressed with the clearly defined salient features of a large number of representative cases. The work has been so organised that no overlapping in instruction has anywhere taken place, each of the clinical teachers taking up those special branches of his subject which a series of selected cases, under his charge at the time, was found most completely to illustrate. By this arrangement it has been possible, in the short space of three weeks, to illustrate the diagnosis and treatment of both medical and surgical diseases in all their branches, whilst such more specialised subjects as mental disease, syphilis, dermatology, ophthalmology, and aural surgery have received a thorough treatment at the hands of their various exponents. It is felt that a post-graduate system of medical training is now an accomplished fact in Edinburgh, and that its continuance and success in the future are fully assured.

ROYAL MATERNITY HOSPITAL.

On the 1st of next month Dr. Croom's quarterly term of office as physician to this institution will terminate, and he will be succeeded by Professor A. R. Simpson for the ensuing three months. Drs. Armitage and Littlejohn, the retiring house-physicians, will be succeeded in office by Drs. Tillie and Fraser and Mr. Scott.

THE ABERDEEN EXAMINERSHIP IN MEDICINE AND PATHOLOGY.

From a large number of applicants for this post, which was recently declared vacant, the Aberdeen University Court have elected Dr. R. W. Philip of Edinburgh as examiner. Dr. Philip is a graduate of Edinburgh University in Arts and in Medicine, and a member of the Royal College of Physicians, and for several years has acted as assistant to the Professor of Practice of Physic, a post in which he has gained special qualifications for the position to which he is now appointed, in having conducted large classes, and in his intimate experience in connexion with the examinations for class honours.

THE WINTER SESSION.

The winter session in the University and extra-academical schools is announced to commence this year on Oct. 20th, about a week earlier than is usually the case. This is a move decidedly in the right direction, since it causes the Christmas recess more nearly to bisect the long courses of lectures delivered during the winter, and, in bringing the session to an earlier termination, makes way for the spring examinations without too great an encroachment upon the period of the Easter recess.

Edinburgh, Oct. 12th.

IRELAND.

(From our own Correspondent.)

ACADEMY OF MEDICINE IN IRELAND.

THE fourth annual general meeting of the Academy of Medicine in Ireland will be held in the Royal College of Surgeons on Friday, the 29th inst., when the report will be read and the election of office-bearers will take place.

COLLEGE OF PHYSICIANS IN IRELAND.

A deputation from this College recently waited on his Excellency the Marquis of Londonderry, and presented him with the following address of welcome:—"May it please your Excellency, we, the President and Fellows of the King and Queen's College of Physicians in Ireland, beg to approach your Excellency with the expression of our devoted loyalty to Her Most Gracious Majesty the Queen, and our cordial welcome to your Excellency on your arrival in this country as Her Majesty's Viceroy. Our College, which derives its

existence from charters granted by Her Majesty's Royal predecessors, King Charles II. and King William III. and Queen Mary, and which had additional powers conferred upon it by Her Gracious Majesty in 1878, has ever been mindful of the important trust committed to it, and has endeavoured to discharge its functions by furthering the advancement of medical science, and by securing a succession of educated physicians for the service of the State. The King and Queen's College of Physicians in Ireland has at various times rendered its aid and professional advice to Government in devising and carrying into effect measures dealing with the public health, and now, as at all times, the College will consider it to be its duty, as it is its anxious desire, to afford every assistance to Her Majesty's Government in all matters relating to both curative and preventive medicine." The Marquis made a suitable reply, and the deputation retired.

HEALTH OF DUBLIN FOR 1885.

During last year the births in the metropolitan area numbered 10,144, and the deaths 9784, or at the rate of 27·6 per 1000. The mortality was below the average for the previous decade. The most fatal zymotic disease during 1885 was measles, which caused 250 deaths; the victims of this disease being almost exclusively children of the poorest section of the population. Next in order of fatality was whooping-cough. In Dublin constitutional diseases always cause a large mortality. Out of a total of 7741 deaths, 1626 were ascribed to constitutional diseases, and 988 to phthisis. Diseases of the respiratory organs were fatal in 1691 instances. The death-rate from phthisis and bronchitis and lung complaints was 10·62, or more than one-third of the total death-rate.

MEATH HOSPITAL.

Matthew O'Reilly Dease, Esq., D.L., has given £100, and has promised a further donation towards the Dease Memorial, in memory of his late father and grandfather, who were both distinguished surgeons of this hospital. The Memorial, according to Mr. Dease's wish, will take the form of permanent improvements. Mr. Dease has been elected a life governor of the hospital.

CALLAN UNION.

The Local Government Board for Ireland have approved of the appointment of Dr. F. Walsh as second medical officer of the workhouse, at a salary of £25 per annum.

Dublin, Oct. 12th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council of the College, held on Thursday, Oct. 14th, at which all the members were present, Dr. Goodhart was elected an Examiner in Medicine, and Drs. J. B. Potter and John Williams Examiners in Midwifery; Sir J. Lister, Bart., was re-elected a Member of the Committee of Management.

On the report of the Committee of Management, the Council adopted the recommendation that any candidate rejected at the Second and Third (or Final) Examination be requested to furnish certificates of having received, subsequently to the date of his reference, further study in the subject or subjects of the examination.

The President stated that he had chosen Mr. H. Power as the next Bradshawe Lecturer, the lecture to be delivered on Thursday, Dec. 2nd, at 4 P.M.

The Council approved of the report to be presented to the Fellows and Members at their meeting to be held on Thursday, the 4th of November next. This report may be had on application on and after Monday, the 18th inst.

A FORTUNATE UNIVERSITY.—Since 1879 (says an American contemporary) the University of Sidney has received donations exceeding a million of dollars. One bequest, known as the Challis bequest, is expected to realise £200,000. The Macleay Natural History Collection, another recent gift, is valued at £25,000, and a sum of £6000 has been promised for the endowment of a curatorship in connexion with it. For the purpose of founding a library, a donation of £30,000 was made.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following candidates have passed both parts of the examination, and become entitled to certificates in Sanitary Science:—

J. R. A. Clark, R. M. Craven, D. W. Currie, C. Forbes, W. H. Gregg, P. Hehir, H. Lingard, O. Scattergood, T. S. Short, J. R. Thomas, A. H. Twining.

ROYAL UNIVERSITY OF IRELAND.—The following have passed the Second Examination in Medicine of this University:—

UPPER PASS.—Robert Forsyth, Hugh T. Gill, *John Hall, *Robert Hastetz, *James Jackson, *George Jenney, James McConnell, John Macpherson, *Allen Mahood, Alexander Morrison, Marcus Quarry, *Joseph Ryan, John Smith, Henry Smyth, William Taylor, *Robert Thompson, William Waddell, Robert Wilson, *John Wolfe. (Those marked with an asterisk will be admitted to the further examination for Honours.)

PASS.—Charles Beattie, Patrick Blewitt, James Buchanan, Andrew Burgess, James Campbell, Joseph Clarke, John Connor, Edward Coffey, William Demery, Thomas Enright, Robert Erskine, Thomas Fisher, Barron Gass, Thomas Hickie, Stuart Irwin, Paul Jennings, Bertram Jordan, John Jordan, J. McCormick, Wm. McIldowney, Thomas MacMahon, William Macnaughton, William Morris, Thomas Obre, Matthew O'Regan, Samuel Parker, Samuel Tate, Richard Thornton, Francis Tweedie.

The following gentlemen passed in subjects necessary to complete the Second Examination in Medicine:—

Thomas Gorman and Henry Jamison.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 7th inst:

Day, Stewart Butler, Berners-street.
Fitz-Henry, George William, Chartwood-street.
Mason, Francis J. Gorringe, M.R.C.S., Rectory-place, Woolwich.
Nash, Charles, Burney-street, Greenwich.
Pettingill, Alfred Ernest Albert, Regent-street, Great Yarmouth.
Sparrow, J. Elliston, Pennington, Millman-street, Bedford-row.
White, Julian H., Clarendon-place, Hyde-park-gardens.

The following gentleman also on the same day passed his Primary Professional Examination:—

Henry Havilland Roe, King's College.

A HOSPITAL FOR ANIMALS has been established at Calcutta, and endowed with six lakhs of rupees.

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—An anonymous donor has given £500 towards the reduction of the debt on the building fund of the above charity.

MACCLESFIELD INFIRMARY.—The late Mr. U. Brocklehurst, of Hanbury Hall, near Macclesfield, has bequeathed £1000 to the endowment fund of the infirmary.

THE MEDICAL MISSION.—In connexion with the opening of the medical mission, an inaugural address was delivered on the 8th inst at St. Martin's Church, Trafalgar-square, by the Hon. and Rev. W. Talbot Rice.

CONSTANT WATER-SUPPLY.—The New River Company has been requested by the Local Government Board to provide a constant water-supply to the southern district of Clerkenwell.

ELECTRICITY UTILISED AS A MEANS OF PUNISHMENT. An ingenious Swiss is said to have devised an electrical whipping apparatus which will inflict the requisite amount of pain without causing unsightly and inconvenient wheals.

CORPORAL PUNISHMENT IN SCHOOLS.—The Birmingham School Board recently decided to dismiss two masters who had been proved to have inflicted corporal punishment on pupils, contrary to the rules of the board.

A NEW COTTAGE HOSPITAL.—A cottage hospital, erected on a site given by Lord Brownlow, and well endowed by Lord Kenyon, was opened on Saturday last, free of debt, at Whitchurch, Salop.

ST. BARTHOLOMEW'S HOSPITAL.—The Senior Open Scholarship in Science, competed for by medical students, has been awarded to Mr. E. Lloyd Jones, jun., B.A., Brooklands, Sale.

UNIVERSITY OF ABERDEEN.—The University Court of this University has appointed the following six gentlemen to be extra-professorial examiners in Medicine in the University:—Dr. J. Macdonald Brown, Edinburgh; Dr. W. D. Halliburton, London; Dr. A. D. Leith Napier, Dunbar; Dr. R. W. Philip, Edinburgh; Dr. Wm. Rob. Smith, London; Dr. Fras. Warner, London.

THE Cairo correspondent of the "Daily News" reports that Dr. Ritchie, of the medical staff, when descending the Cheops Pyramid fell from an enormous height and was dashed to pieces at the base.

A WIDOW LADY named Mount, who has just died at Canterbury, has left by her will a sum of £40,000 to be divided between two of the principal hospitals for eye diseases in London and the county of Kent.

AT the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 12th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £69 was distributed among the several applicants.

HOSPITAL SUNDAY.—Sir P. Cunliffe Owen has, at the request of the Prince of Wales, remitted to the Mansion House a further sum of £200, the amount received at the "Colinderies," by Dr. Aveling's "Mechanical Beggar," from July 10th to October 8th.

BURNING HOUSE REFUSE.—Furnaces for the disposal of house refuse by combustion have been erected by the Whitechapel Board of Works, and are now in full operation. The total cost of the works, including the purchase of the site, is about £13,000.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Library of the College will be closed to-day (Friday), and on Tuesday, Wednesday, and Thursday, at four o'clock. The Museum will be closed on Tuesday and Wednesday, the 19th and 20th inst., for the purposes of the College Examinations.

DR. EDSON, medical officer of the Health Department of New York, has been making inquiry into the quality of the milk sold in that city, and finds that in some instances it was diluted with as much as 40 per cent. of water. This indicates a rather worse state of things, perhaps, than exists in London in regard to this important article of diet.

ST THOMAS'S HOSPITAL MEDICAL COLLEGE.—The following Open Scholarships in Natural Science have been awarded:—Charles Petre Lovell, Scholarship, £100. Medwin C. Clutterbuck, Scholarship, £60. The following obtained the number of marks qualifying for a scholarship: G. M. Winter (prox. acc.), W. B. Winston, P. C. Low, E. T. Whitehead.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—The third annual meeting of this Association was held on the 9th inst. The report read on the occasion spoke favourably of the success of the Society, as shown by the increase in the number of members, and by the growing interest in the objects it has in view.

THE PROPOSED HOSPITAL AT WEST HAM. — The bazaar and exhibition held last week to aid in the promotion of the above-named object seem to have been decidedly successful. The total receipts for the five days are stated to have been above £900. Over 10,000 persons visited the exhibition. The sum required to erect the proposed hospital is estimated at £3000, of which two-thirds have already been subscribed or promised.

GUY'S HOSPITAL MEDICAL SCHOOL.—Mr. Frederic Hewlett Brown, of Magdalen College, Oxford, and Mr. George Marlow Pratt, of Dulwich College, were bracketed equal for the Entrance Scholarships of 125 guineas in Classics, Mathematics, and Modern Languages; and Mr. Bertram Whewell Hogarth, of Yorkshire College, Leeds, that of 125 guineas in Chemistry, Physics, Botany, and Zoology.

DISINFECTION OF CABS.—With a view of assisting the police in checking the spread of zymotic disease, the committee of the Seamen's Hospital have given instructions that the number of every cab which brings to the hospital a patient suffering from contagious or infectious disease should be communicated to the Commissioner of Police. The St. Giles's Board of Works have announced that hackney carriages which have been used for the conveyance of persons suffering from infectious disease will be disinfected by the Board free of charge, and that the driver may be supplied with a certificate of such disinfection by applying to the medical officer of health.

ALL the schools in Fleetwood under the jurisdiction of the School Board are now closed, owing to the prevalence of measles among the children.

SIR WILLIAM LEWIS, as founder of the South Wales Miners' Provident Society, was a few days ago presented with a cheque for £145 16*s.* 8*d.*, the whole of which was made up by subscriptions from 35,000 colliers, each of whom gave 1*d.* In reply, Sir William announced his intention of handing the cheque over to the Merthyr Tydvil Hospital.

PRESENTATION.—A testimonial has lately been presented to Dr. Walker, on his leaving Boulogne-sur-Mer, consisting of a sum of money in a purse, and a silver tea-tray, with the following inscription upon it:—"Presented to T. H. Walker, M.D., by his patients and friends, as a token of their affection and esteem, after a residence amongst them of fourteen years and six months. Boulogne-sur-Mer, France, 30th June, 1886."

STOCKPORT AND DISTRICT MEDICAL SOCIETY.—At the annual meeting of the Society, held at the Stockport Infirmary, on Thursday, the 7th inst., the following were elected officers for the ensuing year:—President: Dr. Higinbotham. Vice-President: Dr. Bride (Wilmslow). Treasurer: Dr. Maclean. Secretary: Dr. Bailey (Marple). Auditors: Drs. Godson (Cheadle) and Bain. Committee: Drs. Ball, Murray, and Jones (Chapel-en-le-Frith). G.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The following office-bearers have been elected for the ensuing session:—President: Mr. F. B. Jessett. Vice-Presidents: Messrs. J. Brindley-James and C. H. Hartt. Council: Messrs. Hughes G. Cable and Thomas Moore; Drs. Ernest Clarke, W. Collingridge, Alexander Forsyth, P. Horrocks, and Fredk. Moon. Treasurer: Dr. Prior Purvis. Secretary: Mr. H. W. Roberts. Librarian: Dr. Alexander Forsyth.

THE BLIND, THE DEAF, AND THE DUMB.—The Royal Commission on the blind, the deaf, and the dumb, have just concluded a tour of visitation, which occupied sixteen days, to the principal institutions of the north of England and Scotland. The considerable amount of valuable information thus collected by the commissioners it is proposed to supplement by the oral testimony of persons connected with the institutions visited.

THE LATE SISTER DORA.—Walsall was on Monday last the scene of an interesting event, in connexion with the memory of the philanthropic work of the late Dorothy W. Pattison, better known as Sister Dora. More than three years ago, Miss Lonsdale had offered to defray the cost of a statue out of the profits of her biography of her deceased friend, and after some demur on the part of the Town Council of Walsall as to the appropriateness of the memorial, the offer was ultimately accepted. The statue, which is of white Cicilian marble, and stands on a pedestal of red granite, was unveiled on the above day, amidst much enthusiasm, by Councillor Beebee, the Mayor acknowledging the presentation on behalf of the town.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—The quarterly meeting was held on Tuesday last in the rooms of the Medical Society of London, the President, Dr. Norman Kerr, in the chair, who proposed a resolution of welcome to Dr. Simon Fitch, of Halifax, Nova Scotia, a member and councillor of the Society. The resolution contrasted the efficient legislation in the interests of the habitual drunkard in Nova Scotia with that in England, in the former colony there being power, by permanent Acts, to deal with inebriates unwilling to surrender their freedom of their own accord. Dr. Walter Dickson seconded the resolution. Dr. Fitch replied, and expressed much gratification at the honour done him, and his deep interest in the proceedings of the Association. A resolution of welcome was also accorded to Mr. Axel Gustafson, author of "The Foundation of Death," on his return from America, to which that gentleman responded. The President pointed to the recently published novel, "Disenchantment," by Mabel Robinson, as a proof that the intelligent English mind was gradually becoming more enlightened on the physically diseased state of the habitual inebriate, this fascinating tale having this teaching as its moral. Among those present were Sir Edwin Saunders, Lord Mount Temple, Dr. George Harley, Dr. Walter Dickson, Surgeon-Major Poole, Dr. George Robertson, Hon. and Rev. Canon Leigh, and Rev. Canon Barker.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BRUCE-AUSTIN, WILTSHIRE STANTON, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer to the Barrow Water-Works.

CARR, J. W., M.B., B.S.Lond., has been appointed House-Surgeon to University College Hospital.

HALL, BEN., M.B.Lond., Second Assistant Medical Officer at Middlesex Asylum, Banstead, has been appointed Superintendent of The Brook Villa Private Asylum, Liverpool.

HALLIBURTON, W. D., M.D., B.Sc., M.R.C.P., has been appointed Examiner in Physiology, University of Aberdeen.

HARDING, CHARLES O'BRIEN, M.R.C.S., has been appointed Surgeon to the Holloway and North Islington Dispensary.

JONES, JOHN THOMAS, L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer to the Second Division of the Whitford District of the Holywell Union, vice Michell.

KEAY, JOHN, M.B., Assistant Physician to the Crichton Royal Institution, Dumfries, has been appointed Resident Medical Superintendent to Mavisbank Asylum, Edinburgh.

LAKE, W. WELLINGTON, M.R.C.S., L.S.A., has been appointed Surgeon to the Walthamstow and Leyton Children's Hospital, vice Mr. Henry Gould, retired.

LEWERS, ARTHUR H. N., M.D.Lond., &c., has been appointed Physician to the Out-patients at Queen Charlotte's Lying-in Hospital.

LOW, A. BRUCE, M.D., M.R.C.P.Ed., has been appointed Honorary Physician to the Sunderland and Bishopwearmouth Infirmary, vice W. H. Dixon, M.D., resigned.

MEEKE, ARTHUR HENRY, M.B., Ch.B. Dub., has been appointed Government Medical Officer and Vaccinator for the District of Caudelo, N.S.W.

PROWSE, WILLIAM, M.R.C.S., L.S.A., has been appointed Medical Officer to the Fourth District of the Axbridge Union, vice Furnivall.

SHIRLEY, MATTHEW B., L.R.C.P.Ed., M.R.C.S., has been appointed (*pro tem.*) Medical Officer for the Southhill District of the Dewsbury Union, vice Stockwell, deceased.

WARREN, HENRY GUY SEYMOUR, L.R.C.P.L., M.R.C.S., has been appointed Visiting-Surgeon to the Gaol at Dubbo, N.S.W., vice Tennant, resigned.

WILKINSON, J., M.B., C.M.Ed., has been appointed Resident Medical Officer to the Eastern Dispensary, Bath, vice Irwin, resigned.

WILLIAMS, D. W., M.B.Lond., M.R.C.S., has been appointed Assistant Resident Medical Officer to the Bristol Royal Infirmary, vice Thurston, resigned.

WILLIAMS, EDWARD, L.R.C.P., L.R.C.S.Ed., L.S.A., has been appointed Medical Officer for the Mold District of the Holywell Union, vice W. Williams, M.D.

Births, Marriages, and Deaths.

BIRTHS.

EAGAR.—On the 6th inst., at Ballygrenane, Listowel, co. Kerry, Ireland, the wife of Oliver Stokes Eagar, Surgeon-Major, F.R.C.S.I., of a daughter.

GARMAN.—On the 7th inst., at The Bungalow, Slingsby, York, the wife of Dr. Vincent Garman, of a daughter.

GIBSON.—On the 1st inst., at Stanley House, Blackstock-road, Finsbury-park, N., the wife of Dr. J. C. Gibson, of a daughter.

HALL.—On the 9th inst., at Laurel Villa, Victoria-road, Surbiton, the wife of Edgar A. Hall, M.B., C.M.Edin., of a daughter.

WHEELER.—On the 12th inst., at Ruvigny-gardens, Putney, the wife of Frederic Wm. Wheeler, L.R.C.P., of a daughter.

MARRIAGES.

FOOKS—DODGSON.—On the 5th inst., at St. Saviour's, Paddington, George Ernest Fooks, Surgeon, of Her Majesty's Indian Medical Service, to Alexina Louisa, eldest daughter of J. C. Dodgson, Esq., late Bengal Civil Service.

KARKEEK—PATON.—On the 9th inst., at Northiam Parish Church, Sussex, by the Rev. J. W. Lord, Paul Q. Karkeek, M.R.C.S., &c., of Torquay, to Elise, daughter of the late A. A. Paton, H. M. British Consul at Ragusa.

SHEEHY—HAWES.—On the 9th inst., at Mapledurham Parish Church, near Reading, W. H. Patmore Sheehy, L.R.C.P.Lond., &c., of Claremont-square, London, son of the late W. H. Sheehy, L.R.C.P.Ed., to Myra, only daughter of the late George William Hawes, of Southfields, Wandsworth, and granddaughter of the late Major Hawes, of Spring-gardens.

WOODSON—SHOUT.—On the 6th inst., at Languville, Lincolnshire, Adolphus Arthur Woodson, M.R.C.S., L.R.C.P., &c., of Sheffield, to Clara Jane, daughter of W. P. Shout, Esq., of Boston.

DEATHS.

COCKELL.—On the 10th inst., at Forest-road, Dalston, Edgar Cockell, M.R.C.S., in his 72nd year.

HAY.—On the 4th inst., at Peterhead, Aberdeenshire, Francis Hay, M.A., M.B., C.M.Aber., aged 37.

STEDMAN.—On the 12th inst., at Great Bookham, Ernest Alan Stedman, lately a Student of St. Thomas's Hospital, third son of Arthur Stedman, Surgeon, in his 20th year.

WATERWORTH.—On the 7th inst., at Quay-street, Newport, I.W., Henry Waterworth, F.R.C.S., J.P., aged 78.

N.B.—A fee of £5 is charged for the insertion of Notices of Births,

Medical Diary for the ensuing Week.

Monday, October 18.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. C. E. Cassal: Food, good and bad. Milk, Sale of Food and Drugs Act.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Opening Address by the President (Mr. R. Brudenell Carter).—Mr. Frederick Treves: Hernia of the Cæcum.

Tuesday, October 19.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Eve: Hemiatropia Facialis.—Mr. Treves: Malignant Cysts of Neck.—Dr. T. D. Acland: Excavation of Lung simulating Pneumothorax.—Mr. Stoker: Cancer of Thyroid.—Mr. D'Arcy Power: Dermoid Cyst of Testis.—Mr. E. H. Fenwick: Carcinoma of Left Lobe of Prostate.—Dr. Savill: Meningeal Hæmorrhage.—Mr. S. Paget: Malignant Disease of Thyroid (card specimen).

Wednesday, October 20.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. R. Thorne Thorne: Infectious Diseases and Methods of Disinfection.

Thursday, October 21.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Living and Card Specimens at 8 P.M. Dr. W. A. Bralley: Rapidly occurring Blindness, with Ptosis and Ophthalmoplegia Externa and Interna.—Messrs. Critchett and Juler: Case of Orbital Tumour.—Mr. W. Adams Frost: (1) Ophthalmoplegia Interna with absence of Knee-reflex, persisting over two years without other symptoms; (2) Pigmentary Retinitis, with a Layer of Pigment on Anterior Capsule.—Mr. W. Lang: Change in Yellow Spot Region.—Mr. Humphry Haines: New Instrument for Facilitating Retinoscopy. Papers:—Dr. Sidney Coupland: Ophthalmoplegia dependent upon Thrombosis of Cavernous Sinuses.—Messrs. Edmunds and Lawford: On the Condition of the Optic Nerves in Head Injuries.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. John Phillips: Hydramnios and its Relation to certain Fœtal Disorders.—Dr. A. Tucker Wise: Some Remarks on Alpine Winter Climate.

Friday, October 22.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. J. F. J. Sykes: General Powers and Duties of Inspectors of Nuisances; Method of Inspection.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Charters Symonds: A case of Removal of the Scapula for Osteo-sarcoma.—Mr. Thomas Smith: Ligature of the Common Iliac Artery with Kangaroo Tendon, yielding of the knot, ligature with silk, gangrene of the limb, death.—Mr. Butlin: A case of Axillary Aneurysm for which the Subclavian Artery was Ligatured in the Third Part of its Course, slipping of the ligature shortly after the operation, re-ligature, collapse, death.—Mr. Wainewright: A case of Vertical Fracture of the Head of the Radius complicated by Fracture of the Coronoid Process of the Ulna, and possibly a Split between the Condyles of the Humerus. Living Specimens:—Mr. S. Paget: Two cases of Congenital Abnormality of the Eyes—(1) Absence of Iris in Mother and Child; (2) Pigmentation of Conjunctivæ.

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—7.45 P.M. Mr. Rorri Fletcher: Pleuritic Effusions and Paracentesis.

Saturday, October 23.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE NON-RETURN OF PHOTOGRAPHS.

WE receive from time to time letters from medical assistants complaining that after replying to advertisements for assistants and enclosing photographs, the cartes are, contrary to custom, retained by principals. This is perhaps a small matter; but the breach of courtesy referred to—the result no doubt of thoughtlessness—is nevertheless often productive of considerable inconvenience, and of aggregate loss, to members of a useful class of workers in the profession.

Mr. Silas Mainwills.—The question is undoubtedly one of the greatest importance, but our columns would not be a suitable place for its discussion.

Dr. Glynn.—In an early number.

USE OF COCAINE IN MIDWIFERY PRACTICE.

To the Editor of THE LANCET.

SIR,—Would Mr. Hartshorne kindly describe a little more fully his preparation of cocaine as used by him in midwifery, and mentioned in his letter in your issue of June 12th, especially with reference to the strength of cocaine solution, as I presume he does use a solution. I should like to use cocaine in this class of work; but out here it is too expensive for country practitioners to experiment in making preparations. The following case is one on which an opinion is requested, as to whether it is one of prolonged gestation or missed menstruation. Mrs. S——, aged about thirty, called on me in January last to engage me for her fifth confinement, which was expected to be about March 20th, reckoning from June 13th, 1885, when she last (to use her own expression) saw anything. The period of quickening was not noticed—in fact, she never had noticed it with any of her previous children. She was not confined till May 9th, a period of 331 days since last menstruation. I have questioned her as to whether she had not made a mistake in her calculations; but she says there is no mistake at all, that morning sickness began early in August (about the sixth or seventh week), and that her feelings at about that period were exactly as with all her other children. Until I saw her in January she was a perfect stranger to me, so I have to take her word for it all; but I may say that when I first saw her I thought from her size that parturition would take place much sooner than she imagined. The child was a fine boy, but in no way remarkable for size.

I am, Sir, yours truly,

G. PEARCE BALDWIN, L.R.C.P. & S.

Murrumburrah, N.S.W., Aug. 23rd, 1886.

A "CURE" FOR HYDROPHOBIA.

The Independent Practitioner says: "In 1806, only eighty years ago, the Legislature of the State of New York passed a Bill, and Governor Morgan Lewis signed and approved it, to pay to a notorious Hessian quack $1000 for his secret remedy for hydrophobia. The remedy was to be published, and its efficacy assured before the money was paid; but the quack's name is found signed in receipt of the sum on the back of the comptroller's warrant."

"*Cure for the Bite of a Mad Dog.*—1. Take one ounce of the jawbone of a dog, burned, or pulverised, or pounded to fine dust. 2. Take the false tongue of a newly-foaled colt; let that be also dried and pulverised. 3. Take one scruple of verdigrease which is raised on the surface of old copper by laying in moist earth; the coppers of George I. or II. are the purest and best. Mix these ingredients together, and if the patient be an adult or full grown take one common teaspoonful a day, and so in proportion for a child, according to its age. In one hour after, take the filings of one half of a copper of the above kind, if to be had; if not, then a small increased quantity of any baser metal of the kind; this to be taken in a small quantity of water. The next morning, fasting or before eating, repeat the same as before. This, if complied with after the biting of the dog and before symptoms of madness, will effectually prevent any appearance of the disorder; but if after the symptoms shall appear, a physician must immediately be applied to to administer the following—viz., three drachms of the verdigrease of the kind before mentioned, mixed with half an ounce of calomel, to be taken at one dose. This quantity the physician need not fear to administer, as the reaction of the venom then diffused through the whole system of the patient neutralises considerably the powerful quality of the medicine; and, secondly, if in four hours thereafter the patient is not completely relieved, administer four grains of pure opium, or 120 drops of liquid laudanum. N.B.—The patient must be careful to avoid the use of milk for several days after taking any of the foregoing medicines.—JOHN M. CROUSE."

Mr. A. G. Taunton.—It might have been better to have used the word "individual," instead of "animal," in the sentence quoted; but as the remark applied to a class of individuals almost equal in number to the class from which it was differentiated, the more comprehensive term was selected. As specifically stated, the arrest of development is not in the nature of an arrest such as that supposed by our correspondent, which would result from an hereditary influence, but is a diversion of development, as we explained. Comparative anatomy makes the matter sufficiently clear. We cannot discuss the point in detail; but there is no hypothesis of difference in kind. It is simply a question of the process of organic development in the individual, and has nothing whatever to do with the type of racial development which determines species.

Probationer had better apply to one of the Nursing Associations.

GUINEA-WORM.

To the Editor of THE LANCET.

SIR,—If "Reader" (*cride* your issue of the 2nd inst.) will try the effects of the cold douche, using ice-cold water, two or three times daily, over the part where the guinea-worm burrows, he will find that the worm will soon appear above the surface. The after-treatment is that recommended by Dr. Williams in your last issue. I have adopted the above-described method in dealing with cases of guinea-worm for many years with good results.

I am, Sir, yours faithfully,

London, Oct. 11th, 1886. SURGEON-MAJOR, I.M.D.

To the Editor of THE LANCET.

SIR,—Two or three small errors of the printer exist in my communication in your last issue on "Guinea-worm," which perhaps, as they convey quite a different meaning, you will allow me to correct. At the eleventh line from the top it should read—"between the free surface *and* the rolled up piece of plaster;" and the last word, next line but one, should be *lightly* instead of "tightly." "Admissible," the first word in the twentieth line, should be followed by *and*.

I am, Sir, yours faithfully,

Truro, Oct. 12th, 1886. D. W. WILLIAMS, M.D.

Mr. R. Jones (Liverpool).—The paper has been received, and is marked for insertion.

Mr. C. B. Townshend is referred to an article in our present issue.

CAUTION TO GUY'S MEN.

To the Editor of THE LANCET.

SIR,—On the 4th inst. I had a visit from a person who informed me that he was a Guy's man of my year, and that he was just going into partnership with his father. He had had the misfortune to lose his purse in Shrewsbury the night before coming to me, and as he had an important engagement to meet his father and uncle in London the following morning he applied to me for the loan of sufficient money to pay his hotel bill and fare to town, the same to be returned the next day. It is perhaps obvious that the latter part of the contract has not been fulfilled.

I am, Sir, yours obediently,

Wem, Salop, Oct. 12th, 1886. B. FARADAY GILES, M.D.

A CURIOUS WAGER.

THE following is extracted from the *Indian Medical Journal* for July. "Two Mahomedans in Hyderabad City made a curious wager the other day, which resulted in the death of one of them. The deceased accepted a challenge that he would stand facing the sun from 8 A.M. to 6 P.M. A certain day was appointed, when a large gathering assembled to witness the *tamasha*, as they styled it. The deceased took his stand, gazing at the sun from the agreed time up to 3 P.M., when suddenly he dropped, foaming from the mouth. Medical aid was soon summoned, but before assistance arrived life was extinct."

A District Medical Officer is obliged to extract the teeth of paupers if he receives the order from the relieving officer. If he receives an order from an overseer he must act upon it; but if it is not a case of urgency he can recover his fee from the overseer. Our correspondent is not bound to attend upon the order of a guardian.

Health will probably find the information he requires in Dr. C. D. F. Phillips' work on Materia Medica and Therapeutics—Inorganic Substances, 1883.

AVULSION OF A FINGER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 2nd there appears amongst the annotations a narrative of a case of forcible avulsion of a finger, occurring in the practice of M. Auché; and as supplementary to such I would like to instance a somewhat similar accident which came under my notice whilst I was in practice some years ago at Fort Augustus, in Inverness-shire.

Two crofters were proceeding in separate carts on their way to get a supply of herrings at the fishing in Loch Hourn. One of them had got into the foremost cart to sit beside his companion, and he had the rope reins of his horse in some way twisted round one of his fingers, in order to have a sure control of the animal which followed in the hindmost cart. For some inexplicable reason his horse came to a sudden standstill, with the result that a severe strain was thrown at once upon the reins entwined about his finger. The immediate consequence was that the finger was completely torn off at one of the joints, bringing along with it a long portion of one of the flexor tendons, which had evidently slipped away right from its insertion. The poor man was brought to my house, a long distance from where the accident happened, and when seen by me he was in a fainting condition, and complaining of intense pain along the course of the sheath of the tendon and up the arm. There had been very slight hæmorrhage from the stump, and I applied some simple dressing on lint and got him conveyed to the inn near by, where I saw him later in the day. He was still complaining of great pain, although warm fomentations, &c., had been assiduously applied to the painful parts. As his home was a long way off, and as he was most anxious to get back there, I advised him to remain for the night where he was, and then go on in preference to the Northern Infirmary, Inverness, as I feared that he might not be in a fit state to undertake a long journey by road to his home. Next day he was received into the Inverness Infirmary, I believe; and I understand that he made a good, although somewhat protracted, recovery. When he came to me on the day of the accident he produced from his pocket the finger rolled up in a piece of rag. I advised him to preserve it for the inspection of the gentleman connected with Inverness Infirmary.

That a tremendous amount of force had been expended in causing entire separation of the finger is self-evident from the suddenness with which avulsion had been effected in this case, and it serves to demonstrate to some extent the accuracy of M. Farabœuf's statement that a force of about 3 cwt. is required to effect separation. It has also appeared to me somewhat remarkable that symptoms of tetanus did not supervene as a result of such severe laceration and stretching of nerves, tendons, &c.

I am, Sir, your obedient servant,
JOHN COCHRANE, L.R.C.P. & S. Ed., &c.

Broadford, Skye, Oct. 8th, 1886.

T. A. D.—The College of Physicians issues no syllabus of books to be read for their certificate of hygiene; but the examination professes to be of the same standard as that at Cambridge, and anyone can purchase at the Cambridge Warehouse, 17, Paternoster-row, the papers given at the last examination, together with a syllabus of the books recommended. The worst of this syllabus is its extreme length; but after a selection has been made from it we would, having regard to the papers given at the College of Physicians, advise the candidate to study the recent reports of the Medical Officer of the Local Government Board, which may be regarded as containing the most recent information on medicine in its relation to public health.

M.B.—As a number of fresh regulations are now being made about medical matters in Spain, our correspondent will find it best to communicate with H.B.M. consul in Madrid.

APPLIANCE FOR BOWED LEGS.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me what is the best kind of splint or appliance to use for a young child just beginning to walk suffering from bowed legs? I am, Sir, yours truly,

Oct. 6th, 1886. HOMO.

STROPHANTHUS.

Messrs. CHRISTY AND CO. have forwarded for our inspection a beautiful specimen of the pod of strophanthus. On opening this pod by unrolling its thick skin a number of the seeds, with their handsome plumose appendages, are seen. It has been found that since the publication of Prof. Fraser's experimental results the whole pod and seeds and other parts of the plant may be used to advantage in the preparation of the tincture.

A Hospital Nurse wishes to know if it is customary for the house-surgeon of a hospital to remain behind the screen when the sister of the ward is passing the catheter on a woman, the case being an ordinary one. The reply must be in the negative, and few house-surgeons would feel that their duty compelled them to be present. The large majority would much prefer that the necessary manipulation should be unembarrassed by their presence and that they should be made acquainted with the result, always providing that they are satisfied that the sister of the ward possesses the necessary skill. In many cases it is of the utmost importance that the catheter shall have been properly introduced and the condition of the bladder ascertained.

Bonanza.—We believe degrees obtained in other countries are not recognised in Italy. Holders of the M.D. of universities of high standing may, however, be admitted to the examinations for the grade to which they aspire. Exemption from examination can only be obtained by the favour of the Superior Council of Public Instruction.

H. D.—There is not much to choose between Kiel, Bonn, and Leipsic. A *thorough* knowledge of German is not absolutely necessary at either of the above universities.

THE CASE OF UNQUALIFIED ASSISTANTS.

To the Editor of THE LANCET.

SIR,—As the columns of THE LANCET are ever open to the humblest members when they have a grievance to lay before the profession, I beg for a little space to state the troubles of competent unqualified assistants, and, as one example among many, will give my own case.

I commenced my studies in 1861, by passing the preliminary examination of the College of Surgeons. I attended during two winter and two summer sessions one of our foremost schools of medicine, passing my class examinations at the end of each course of lectures. During the recess I attended a county hospital (seventy beds), under the instruction of the attendant physician and surgeon. Previously to the commencement of my third year my father met with pecuniary reverses, which compelled me to remain at home with the hope of being in a position to return to lectures at a subsequent session. During my enforced absence I carried on my studies at the infirmary. When the time came to resume my collegiate studies I was unable to do so, but was obliged to take an assistancy (at a very small salary). I have now been twenty-two years acting as assistant, four years of which I held the post of acting house-surgeon to a country hospital of thirty beds, nominally resident dispenser with entire charge. I have during eight years taken most of the duties of a union hospital, and occasionally had sole charge of a large practice for weeks together. I have attended over 600 cases of midwifery, I believe, successfully, and more than once, when promptitude made it a question of life or death, carried out successfully a serious operation. I have kept myself posted through your columns on medical and surgical subjects which are of interest to the profession; and although my testimonials are all of the highest class, yet I have never been able to obtain beyond £40 per annum for my services.

Now, I take my case as one of many. I consider myself quite as well up in the practical part of my profession as many who are legally qualified, yet my means will not allow me to complete my curriculum; and even if I were in a position to do so, I feel that at my age the difficulties of anatomy, physiology, &c., would be too great to reconquer sufficiently so as to pass a modern examination. I might ask what proportion of general practitioners of twenty years' standing could pass the necessary examination after one or even two years' study. I would pray therefore of the Medical Council to give a little consideration to our case, and in their legislation for the welfare of the future make a slight recognition of the rights of those who have given the best of their lives to the practical study of their profession under far greater difficulties and hardships than their more favoured masters. Surely, even a ten years' apprenticeship must bring some knowledge to a man of intelligence when he is interested in his work, as those of our profession must be. As for myself—if unqualified assistants are to be entirely debarred from work,—I am too old to learn a trade; so there is nothing before me but the workhouse. I am, Sir, yours faithfully,

October 11th, 1886. HOPEFUL.

QUEENSLAND AS A FIELD FOR MEDICAL PRACTICE.

A CORRESPONDENT, a *poitrinaire*, writes for information as to the prospects at present offered by Queensland as a field for medical practice.

Dr. Kühner (Frankfurt).—The matter has scarcely sufficient interest to demand notice.

W. Rawlinson should write to the Editor of "The Hospital," Sardinia-street, Lincoln's-inn-fields.

TESTS FOR CANDIDATES.

A CORRESPONDENT suggests that candidates be subjected to examination as to their views on points of reform that have not yet been obtained, such as the size of the Council, the proportion of Direct Representatives, the introduction of a true one-portal system in each division of the kingdom, greater stringency of the penal clauses, the conditions upon which foreigners and colonial practitioners should be allowed to practise, &c.

Inquirer.—No doubt a *locum tenens* is legally bound to hand over to his principal all fees received from him for professional work done by him during the time of his engagement. But, on the other hand, there would appear to be prevailing a general custom by which a principal allows his representative one-half—in some cases even the whole—of fees derived from necropsies, evidence given before Law and Coroners' Courts, and the signing of lunacy certificates.

Mr. S. W. Thomas.—Though perhaps under no legal obligation to do so, a practitioner should attend a case if requested by a policeman.

"A NEW AND IMPROVED CLAMP FOR HÆMORRHOIDS."

To the Editor of THE LANCET.

SIR,—I am greatly obliged to Mr. Brett for his testimony in favour of my clamp, and regret that I did not see his letter last week. With regard to his suggestions, I do not quite understand how the instrument could be curved. I think he will find that, given an able assistant and the bowel well exposed, he will never have any trouble in applying the clamp. The instrument was made in various sizes, and the present form was selected after very careful consideration and experiment. The screw was purposely made slow, to gain the remarkable power which is characteristic of the clamp, and the few extra seconds occupied in operating are amply atoned for by the advantage obtained.

I am, Sir, yours very faithfully,

Park-street, W., Oct. 12th, 1886. CHARLES J. SMITH.

Mr. H. Heriot-Hill.—Brnck's Australasian Medical Directory and Handbook (Baillière, Tindall, and Cox) will give the information desired.

"PHARYNGEAL AND LARYNGEAL 'NYSTAGMUS.'"

To the Editor of THE LANCET.

SIR,—In my note of last week under the above heading, page 702, the word "cerebral" in the fourth line should be *cerebellar*. I may add that I have just seen the autopsy of a patient (also under the care of Dr. Gowers for tumour in the middle lobe of the cerebellum) in whom a growth of the size of a walnut was found in that situation, causing some *general* pressure on the medulla. There was ocular nystagmus, but no clonus of pharyngeal or laryngeal muscles.

I am, Sir, yours truly,

Oct. 11th, 1886. HERBERT R. SPENCER, M.B., B.S. Lond.

ERRATUM.—In an annotation on "Medical Works and the Law of Copyright," published in our issue for Aug. 21st, the name of the journal referred to as having exposed the unfortunate state of that law was erroneously printed "American Medical Journal," instead of the *Journal of the American Medical Association*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Percy Boulton, London; Mr. W. Curran, London; Mr. Silas Mainville, London; Dr. Strange, Worcester; Dr. Barnes, Carlisle; Mr. Nelson Hardy; Dr. Kühner, Frankfurt; Mr. C. J. Smith, London; Mr. A. B. Clarke, Shebbear; Mr. R. PROCURED

PELVIS HÆMATOCELE,

Delivered at Queen's Hospital, Birmingham, Sept. 3rd, 1886,

BY LAWSON TAIT, F.R.C.S., M.D. (HON.), &c.

GENTLEMEN,—A trial which has recently taken place in Liverpool has given a special interest to the subject of hæmatocele, and that alone would justify me in taking up a considerable part of your time in discussing this extremely interesting subject; but, in addition to this, I desire to draw the attention of my professional brethren to this particular lesion, because it seems to me that the confusion which exists about it becomes deeper and deeper, and not only is there no justification for any confusion at all, but it may be very easily corrected. Our attention was drawn to the subject—in fact, it may be almost said that the question of hæmatocele was introduced to professional notice—by the appearance of a treatise on Diseases of Women by Drs. Bernutz and Goupil, translated by Dr. Alfred Meadows, and published by the New Sydenham Society in its English form in 1866. It appears to me that a more careful study on the part of writers of text-books on gynæcology of this very admirable treatise would have prevented very largely the confusion of which I have to complain. For instance, if we take one of the most recent text-books on gynæcology—that by Dr. Emmet of New York—we see that throughout the chapter on this subject this confusion is remarkably prevalent. It begins with the definition that hæmatocele is "an accidental collection of blood in the pelvis, either in the peritoneal cavity or outside the peritoneum, or within the connective tissue of the pelvis." The definition is faulty to begin with, because the second and the third varieties must of course be classed together, and to class under the same name—the common name of hæmatocele—two conditions which must be so absolutely apart as hæmorrhage within the peritoneal cavity and hæmorrhage outside it, is the very fountain and origin of all the confusion which has arisen. Dr. Emmet quotes Nélaton as having given the first accurate description of the pathology of the lesion; but, in reality, Nélaton's views, from the very words he coined to express them, are very largely answerable for the confusion. M. Nélaton regarded the origin of hæmatocele as being from the rupture of a Graafian follicle, the bleeding naturally gravitating from the surface of the ovary to the bottom of Douglas's cul-de-sac, the most dependent point, and for this the term he invented was "retro-uterine hæmatocele." On page 228 Dr. Emmet gives a diagram labelled a "retro-uterine hæmatocele," in which the section of the blood-clot is clearly enough placed behind the uterus; but a glance at it will show that such clot never could possibly arise from an ovary, so that either Dr. Emmet is wrong in his notions of the pathology or he has altogether misunderstood M. Nélaton. On p. 231 he gives a diagram which is really the diagram intended by Nélaton, but in which the blood-clot is peri-uterine, and not merely retro-uterine; and therefore the case in the second instance comes under the definition and title which we owe to Simpson.

Between the appearance of the first real essay on the subject by Bernutz in 1848 and the translation of his larger work in 1866 a great many contributions to the literature of this subject appeared, each of which advanced some peculiar theory on the subject, and to all of these there may be urged the objection that they were too exclusive, and they did not in any instance, as it appears to me, grasp the whole pith of the case. The word "hæmatocele" is a convenient though not very accurate term, and so long as it is limited to the idea of an effusion of blood it may be taken as the basis of our consideration. The moment, however, such terms as *true* hæmatocele and *false* hæmatocele were introduced confusion reigned supreme. Bernutz held that true hæmatocele consisted of an effusion of blood within the peritoneal cavity, whilst Simpson argued that it could never be an intra-peritoneal effusion. What I am inclined to advise, and for reasons that will be given immediately, is that the phrase "pelvic hæmatocele" ought to be retained to cover all effusions of blood which have their origin in the pelvis. This I advise because it would cover the vast majority of cases of effusion of blood into the peritoneal cavity, for if we exclude the results of traumatic lesion there are very few effusions of blood into the peritoneal cavity which have not a pelvic origin—a fact which is at once indicated by the extreme rarity of the occurrence in men. With this simplification we can look over the great bulk of the literature on this subject with a certainty of arriving at more logical conclusions than if we did not accept the limitation. Bernutz and all other writers agree in recognising the fact that any effusion of blood must be regarded rather as a symptom than a disease of itself, and this is true enough if we are discussing merely the etiology of the condition; but if we regard the condition in itself as an entity we certainly cannot accept this as a limitation, for, whatever the origin of the effusion may be, the moment the effusion is in existence it becomes in itself a disease, and sometimes an extremely severe one. But in the two great classes into which I am about to divide hæmatocele this is far more true about the first class than it is about the second, and this is the first indication that we get of the differences which are found to exist between the two classes. This difference is created *ab initio* by differences in the anatomical relations of the effusion.

In the pelvis—indeed we may take the whole abdomen, and say in the abdomen—an effusion of blood must be either within the peritoneum or outside it. And let us just speak for a moment on what the primary, what the initial result is in any effusion of blood under these two different circumstances. Let us take an imaginary case of rupture of a bloodvessel in the neighbourhood of the kidney by reason of a blow or other injury. Effusion of blood in that neighbourhood must of necessity be extra-peritoneal; it would travel through the cellular tissue, and by reason of the very fact that it had so to travel, provided there was no rupture of a vessel into the pelvis of the kidney, the effusion would be limited, the interstices of the cellular tissue would form the very best of all known hæmostatics, and I find it difficult to imagine that an effusion of blood—let us call it a hæmatocele—in the neighbourhood of the kidney could be so extensive as to be fatal, always supposing it was not a main trunk which had been wounded. But, on the other hand, if we imagine, from some cause or other, a bloodvessel of the kidney bursting into the cavity of the peritoneum, there would then be no natural hæmostatic to assist in the arrest of the hæmorrhage; the bleeding would go on indefinitely, and unless some means could be secured to assist nature in arresting that hæmorrhage, the patient would almost with certainty die.

Let us now take another illustration. Suppose that a small vein on the posterior peritoneal surface of the uterus were to rupture and to bleed into the peritoneal cavity, there the blood would of course naturally tend to coagulate, but not in the same way as when extravasated into the connective tissue. All of us who have experience in abdominal surgery know that when blood flows in quantity into the peritoneal cavity, probably by reason of its dilution by the lymph always present there and easily excited into excessive flow by any abnormal condition, it does not show much tendency to coagulate, save in a very fitful and fragmentary way. One of the most remarkable proofs of this is the influence of the drainage-tube in arresting hæmorrhage. If the cavity is kept dry by frequent withdrawal of the blood oozing from torn pelvic adhesions, the bleeding will soon stop; but if drainage is not kept up the bleeding will probably prove fatal. Supposing, on the other hand, that a small vein ruptured in the tissue and between the folds of the broad ligament, we should again have exactly the same condition as I have imagined to exist about the kidney; in fact, you would have it still more marked, for, in the first place, the cellular tissue through which the bleeding could permeate is much more limited in quantity than it is in the neighbourhood of the kidney. Again, we have a space between the folds of the broad ligament which is not capable of rapid distension to an indefinite extent; the broad ligament, when distended, forms a limited cavity, and we shall then have two processes by which the tendency to excessive hæmorrhage is arrested; the first is the natural tendency on the part of the interstices

of the broad ligament to limit the bleeding; and, again, the pressure of the broad ligament itself, as a membrane distended and resisting further distension, exercises pressure upon the bleeding point, and becomes a powerful natural hæmostatic.

These anatomical considerations alone, were they supported by no other facts at all, would be enough to persuade us into an acceptance of the division, which has often been described but never precisely laid down by writers on this subject, of pelvic hæmatocele into the two classes of extra-peritoneal and intra-peritoneal, the former corrected and checked by two powerful agencies which are absent in the latter, whilst the hæmorrhage in intra-peritoneal hæmatocele is actually favoured by the dilution of the blood as it passes out of the bleeding vessels. The confusion which has arisen from the want of a recognition of the two classes of cases of intra- and extra-peritoneal may be seen by taking up any text-books on the subject and turning to the allusions which are made as to the frequency of the occurrence of hæmatocele or to its differential diagnosis, and still more to its treatment. Thus Dr. Emmet says: "If we limit the acceptation of the term 'hæmatocele' to an accumulation of blood passing into the peritoneal cavity, the accident is comparatively a rare one; but if it is held to embrace all blood accumulations in the pelvis, the occurrence is certainly a far more common one than the profession at large have any conception." If we accept the first sentence of this passage as alluding to intra-peritoneal hæmatocele, the statement is relatively correct; and if we accept the second sentence as referring to extra-peritoneal hæmatocele, the statement is absolutely exact; but if we go a few pages further on in Dr. Emmet's book, we find him attempting to make a differential diagnosis between hæmatocele - of which he has given no precise definition either for extra- or for intra-peritoneal effusion—and tubal pregnancy, and the confusion becomes positively amazing; for it will be seen as we proceed that for intra-peritoneal hæmatocele by far the most common cause is the tubal pregnancy, for which Dr. Emmet desires to find a differential diagnosis. This is what he says upon treatment: "Surgical interference has been advocated by many in its practice, and been urged as the necessary procedure at an early stage. Unquestionably cases must occur when the surgeon would be wanting in sense of duty if he did not assume the responsibility and puncture the mass. But with a large majority of cases such interference would be criminal, as it needlessly places the life of the patient in jeopardy." Here, again, what Dr. Emmet says is absolutely true about extra-peritoneal hæmatocele, and it is absolutely untrue about intra-peritoneal effusion. I only desire to say I have taken up Dr. Emmet as an example of this confusion in English writings because his work happened to be the first text-book on gynæcology which caught my eye on my book-shelf as I started to write this lecture. If we accept the anatomical and physical facts before alluded to as a basis, we shall find that it is not a difficult matter to reconcile a very large number of discordant facts and many discrepancies in the views of various authorities; in fact, the whole story of hæmatocele may be reduced from confusion into order. We shall find also that the two varieties of hæmatocele are different in their relative frequency, in their causation, in their history and course, particularly in their relative fatality—different in their symptoms and in the signs by which they may be diagnosed, and, finally, in their demand for surgical interference.

Dr. Bernutz has expressed an opinion, to which I have already alluded, that "the bloody tumour which is left as the remains of a hæmorrhage has no right to be regarded as a specific disease, apart from what has caused it." This is true, I hold, of intra-peritoneal hæmatocele, but not of the extra-peritoneal variety. When hæmorrhage into the broad ligament occurs, the arrest of the hæmorrhage has been brought about by nature's own methods almost before the accident has been diagnosed, and therefore all we have to do with is the thrombus, and in the great bulk of cases that may be, and generally is, let alone. But cases do arise, as I shall tell you by-and-by, when it becomes a serious disease. But if the sac of the broad ligament bursts out into the peritoneal cavity, the hæmostatic pressure is relieved, the bleeding goes on, the two forms of the lesion coexist, and the patient bleeds to death. I have seen no such case, but more than one is faithfully recorded by Bernutz. Such a case is recorded by Goupil, and is a perfect example of what I can fully believe to be possible, though I have never seen it, therefore I quote it at length.

S——, aged thirty-two, from a delay in menstruation, thought herself pregnant, and regarded a metrorrhagia which occurred as an abortion, though she had seen no trace of an ovum. On admission, the abdomen was distended and very tender on pressure, and it was resonant on percussion. The cervix was open, and the uterus was pushed somewhat to the left and forwards by an enormous swelling which was behind it. The posterior cul-de-sac was occupied by a fluctuating tumour, which was felt filling up the pelvis entirely, and the fluctuation was very distinct. The diagnosis was (and I regard it as one of the most brilliant on record) intra- and extra-peritoneal blood-tumour, probably accompanied by extra-uterine gestation. She gradually grew worse, and died on the third day after admission. She died because, in 1855, M. Nonat, under whose care she was, had not been infected by the restless spirit of surgery let loose since 1878, which has done so much to save cases such as this.

The post-mortem record of this case, however, is a perfectly peculiar record of facts. In the peritoneal cavity about twenty-five ounces of black fluid blood and clot were found, constituting the intra-peritoneal hæmatocele, the cause of the patient's death. When that was removed an ovoid tumour was observed covered by the peritoneum of the broad ligament. It seemed to be formed by a mass of blood. This was the extra-peritoneal hæmatocele. At the bottom of the left recto-uterine cul-de-sac, the peritoneum forming the posterior layer of the broad ligament presented a perforation with a communication between the recto-vaginal cul-de-sac and the cellular tissue, separating the peritoneal layers of the left broad ligament. On making an incision into the ovoid tumour, a small fœtus was discovered.

The importance of this record cannot be over-estimated, for it shows, as I shall tell you afterwards, how some cases of broad-ligament hæmatocele arise. It shows that broad-ligament hæmatocele may occasionally be fatal by becoming intra-peritoneal hæmatocele, and it shows us (this case has shown me) how twenty-four out of twenty-five of such cases may be saved from death. Further, it proves, what is perhaps not very pertinent to the present discussion, that the views I have advanced about the tubal origin of all extra-uterine pregnancies are correct. The only other case of this kind familiar to me is one very imperfectly narrated by Duverney as having occurred in 1712. These two cases are all the records I have found of the coincidence of intra- and extra-peritoneal hæmatocele, and the combination was due in both instances to rupture of a broad-ligament pregnancy with hæmorrhage into the peritoneum. Both cases ended fatally by reason of the hæmorrhage into the peritoneum. I have seen dozens of cases of broad-ligament hæmatocele, and have never met with a fatal one. I have seen over fifty cases of intra-peritoneal hæmatocele, all resulting in death, save those (with one exception) in which I have performed abdominal section for the purpose of obviating death; so that we find a very wide difference in the results of the two classes of cases in my experience. It will also be found that when the real difference between the varieties is understood, it will explain all the discrepancies in the views held by various authors, and all the confusion will cease.

I propose to deal first of all with the extra-peritoneal hæmatocele, and to give first in detail a case which proves in every way its character and relations, and which illustrates also one of the exceptional instances in which it requires to be interfered with.

C. T——, aged twenty-six, was placed under my care in December, 1883, by Dr. Faussett of Tamworth, on account of a large ovarian tumour. I operated on Jan. 3rd, 1884, and removed a cystoma of the left ovary weighing about 14 lb. There were no adhesions, the pedicle was long and thin, and the operation was as easy as possible. A metrostaxis appeared about twenty-four hours after the operation, as is usual after such operations, the only peculiarity in this instance being that the loss was very abundant. It suddenly ceased after being present for about twelve hours, and immediately the patient was in great pain. From having seen the same accident under similar circumstances very frequently, I knew at once what had happened. I examined and found, as I suspected, a large hæmatocele of the left broad ligament. The hæmatocele increased slowly in size until a tumour could be felt above the brim of the pelvis, and the patient suffered greatly. I also found that the rectum was completely blocked, as I had seen it often before, by a stricture caused by the effused blood dissecting round the

rectum outside the peritoneum. This is one of the signs of broad-ligament hæmatocele which has not yet been noted by any writer with whose work I am acquainted, and it is of great importance. It does not—indeed, it cannot—occur in an intra-peritoneal effusion. In the case of C. T——, I tapped the hæmatocele from the vagina and drew off a large quantity of tarry blood; but in fourteen or fifteen hours the sac had filled again and the patient had become exsanguine. I therefore reopened the abdomen, opened the distended cavity of the broad ligament, emptied out the blood fluid and clots, sponged it out with vinegar-and-water, fastened the edges in the aperture to the edges of the parietal wound, and placed in a drainage-tube. The patient then made a rapid recovery. I only want you to note that this second operation made it absolutely certain that the effusion was in the cavity of the broad ligament and not in the peritoneal cavity, for the peritoneal covering of the blood mass was perfectly free from adhesions, and its entire relations could be made out with the greatest ease, quite as easily as if it had been a post-mortem instead of an ante-mortem examination.

Speaking of a series of cases by Nonat, M. Bernutz says, very quaintly, that there should have been at least one necropsy, in order to demonstrate the legitimacy of the different diagnoses that is, between what he calls true (intra-peritoneal) and spurious (extra-peritoneal) hæmatocele. But these five cases recorded by M. Nonat are precisely in point in the present discussion, for four of them were diagnosed by that eminent gynæcologist as being the subjects of extra-peritoneal effusion, and they all recovered, whilst the patient in whom he diagnosed intra-peritoneal hæmorrhage died, and M. Bernutz was gratified by an accurate post-mortem record. Nothing could prove more satisfactorily than this what I contend for, that it is the anatomical relations of the two kinds of hæmorrhage which make all their differences; and now that we examine them carefully before death, and by that very examination prevent death by curing them, we get the first corroboration of all that M. Bernutz has said.

Of extra-peritoneal hæmatocele there are only two causes known to me, one very common and one very rare. The first is sudden arrest of a metrostaxis, which may either be normal menstruation or the pseudo-menstruation which occurs so constantly after abdominal operations. The case I have just detailed is a typical example of what occurs very often after any operation on the broad ligament, and to the inexperienced surgeon is a fertile source of worry. The accident is always indicated by the sudden access of pain, and often an alarming feeling of faintness. The pulse always rises, and sometimes the temperature does so too. On examination the uterus will be found to be fixed on one side, sometimes on both, and this occurs with a suddenness that puts inflammatory effusion out of the question altogether. In the majority of cases the effusion is not extensive enough to be felt above the brim of the pelvis, but in severe cases it is, and then it forms a rounded and distinctly limited tumour, with a feeling of distinct fluctuation. I cannot form any exact estimate of how many cases of these operative hæmatoceles I have seen, but it certainly is not less than fifty, and is more likely to be seventy or eighty, and I have been induced to meddle only with the one I have narrated. In every case in which I have diagnosed the condition the patient has recovered, and in the necropsies which have been made upon cases operated upon by me no record of the incident occurs, so that I conclude it is an accident very nearly if not quite devoid of mortality. Its only drawback is that it delays convalescence for ten or fourteen days, and otherwise I believe it to be of no account at all.

Extra-peritoneal effusion of blood is also very common apart from cases of operation, but by reason of the same sudden arrest of a metrostaxis. Its symptoms in such cases are very much what I have described—sudden pain, a feeling of faintness in severe cases, with a rise of pulse. On examination, the uterus is felt fixed and generally pushed forwards, with a boggy swelling behind or on one side of the uterus, and, if the effusion be large, the mass is felt distinctly limited by the distended broad ligament above the pelvis, this latter condition being the essential diagnostic difference between the two varieties of hæmatocele. An intra-peritoneal hæmorrhage unlimited in quantity or by membrane has never yet been felt by me as a defined tumour above the brim, and I have now had a large experience of such cases, confirmed by operation or post-mortem examination.

Cases of effusion of blood into the broad ligament by sudden arrest, or at least associated with sudden arrest of menstruation, are very common, and I am sure that large numbers of these occur without the patients thinking it worth while to ask for medical assistance, and they get quite well without it. It is, as I have said, a condition probably almost free from primary mortality, and has only a remote secondary mortality when the thrombus breaks down and suppurates, and brings about the tedious condition of pelvic abscess.

Effusion of blood into the broad ligament occurs from another cause, much more rare and probably much more fatal, certainly much more serious—I mean rupture of a tubal pregnancy about the twelfth week of its existence. It is now pretty well admitted that the scheme of the pathology of extra-uterine pregnancy which I advanced some ten years ago covers and explains all the facts of that curious condition, and now it is capable of being used to help us to understand pelvic hæmatocele. Briefly, this view is that impregnation under normal conditions can and does occur only in the uterus. So long as the ciliated epithelium is in action in the tubes, spermatozoa cannot enter them, and the ovules cannot adhere to their walls. But the moment an ovule reaches the cleansed and fresh endometrium infiltrated with spermatozoa, its adhesion occurs. Destruction of the ciliated epithelium of the tubes by desquamative salpingitis reduces the internal tubal surface to the condition of the endometrium, and then entrance of the spermatozoa, impregnation, and adhesion of the ovum are possible, and we have the occurrence of tubal pregnancy. The tube is distended by the growing ovum, and, as it is not capable of indefinite distension, it ruptures, and the seat of rupture seems to be determined by the site of the placenta, where the sinuses have so channelled the walls as to weaken them greatly. A glance at a section of a Fallopian tube will show at once that there are two areas in that section which will severally give very different results, as one or other of them is the site of the rupture. One is much the smaller of the two, and is situated between the layers of the broad ligament, forming, as it were, an ideal roof to the cavity of that space. Rupture here of course means that hæmorrhage occurs into the cavity of the broad ligament, and that an extra-peritoneal hæmatocele results. Such a case may, as I have already proved from Bernutz, become fatal by a further rupture of the broad-ligament cysts and hæmorrhage into the peritoneal cavity. But I feel sure that the great majority of these cases end then and there by the natural cure as mere extra-peritoneal hæmatoceles; the ovum dies and everything is absorbed. I am quite sure I have watched several cases of this kind. In rare exceptions the ovum is not killed, but develops into a broad-ligament pregnancy, formerly known as the "sous-peritoneo-pelvienne" variety of Dezeimeris. I have had seven cases of this kind which I have operated upon, saving six of the mothers and three of the children. Every one of the cases of extra-uterine pregnancy operated upon at or after the full time with which I am familiar comes easily within this explanation, and it makes what is an otherwise wholly unintelligible jumble in physiology as well as pathology quite simple.

The conclusions therefore are that, save under three sets of circumstances, extra-peritoneal hæmatocele is an accident perfectly free from danger. These are—(*a*) when a secondary rupture of the cyst occurs with continued bleeding into the peritoneum; (*b*) when it is merely a stage in the growth of an extra-uterine pregnancy; (*c*) when it goes on to suppuration. I have now to speak of this third condition.

I do not think that suppuration of a broad-ligament hæmatocele is very common, and yet I have met with quite a large number of cases. Of course by the ordinary methods of proceeding, and those which certainly ought to be adopted in the milder cases, it would be very difficult indeed, if not impossible, to make anything like an exact differential diagnosis between a suppurating hæmatocele of the broad ligament and several other conditions which I need not specifically allude to, and therefore any assertions concerning them, after dealing with them as they used to be, and as I say they ought to be dealt with in the majority of instances, by tapping from the vagina, may easily be met by the criticism adopted by M. Bernutz against M. Nonat, that at least one necropsy ought to be in existence to prove the assertions. I have, however, already pointed out that an abdominal section performed before death is for such a purpose as this quite as satisfactory as a post-mortem

examination. In the 63rd volume of the Transactions of the Royal Medical and Chirurgical Society, I published a series of six cases in which I had adopted, for reasons of extreme seriousness, an abdominal section for dealing with pelvic abscesses which otherwise would have opened out in the usual disastrous ways. I say there that "these six cases have all been, so far as I could discover, cases of suppuration occurring in pelvic hæmatoceles," and I may at once dismiss this question with saying briefly that this depended upon the fact that in clearing out the cavity of the abscesses I removed a considerable quantity of laminated, broken-down old clot. Of these cases I select only one as a characteristic example, to illustrate alike the pathology and the treatment of these cases. Anyone who desires to obtain further information on the subject will find it at page 344 of the last edition of my book on Diseases of the Ovaries.

The patient in this case was sent to me by Dr. Flynn of Birchills. She was forty-five years of age, and had never been pregnant, save one doubtful miscarriage soon after marriage, nineteen years before. Symptoms resembling those of hæmatocele had occurred eight months before I saw her, and since that time she had been losing flesh, had lost her appetite, was troubled by constant thirst and night sweats, and had a rising night temperature. The uterus was fixed in a mass of effusion occupying the left broad ligament, and partly the right one also, and the mass on the left side encircled the rectum, forming a pronounced stricture, as hæmatoceles of the left broad ligament frequently do. No point of fluctuation could be felt in the pelvis, but the symptoms pointed clearly to the presence of pus. I therefore determined to open the abdomen, and readily obtained the consent of my colleague to this proceeding. On reaching the peritoneum the two layers were found to be adherent, so that the cavity was not opened. A large abscess was opened just behind the base of the bladder, between which and the uterus it principally lay, but stretching round behind the rectum. The floor and posterior wall of the abscess were found to consist of organised blood clot, so that its origin had been in a blood effusion into the broad ligament. A glass drainage-tube was inserted, and this was changed for one of Chassaignac's wire tubes on the eleventh day after the operation. She sat up on the twenty-first day, and the tube was finally removed on the twenty-sixth. She went home on the thirtieth day, perfectly well, and has remained so ever since, now nearly six years.

About thirty of such cases have been operated on by me, and all have recovered. I say about thirty, because I could not be sure that all these cases of pelvic abscess originated in suppurating hæmatocele, though the facts prove that the majority of them did so; and therefore I conclude that extra-peritoneal hæmatocele, though rarely fatal, has serious consequences in a fairly large proportion of cases.

How different it is with intra-peritoneal hæmatocele you shall shortly hear. My first experience of it was one of the saddest things I have ever known. A young married lady, one of the most charming and brilliant of women, the daughter of an author known wherever the English language is spoken, the wife of one of the most brilliant of surgeons, died after a few hours' illness, and on post-mortem examination a ruptured tubal pregnancy was found to be the cause of an enormous intra-peritoneal hæmatocele.

Another case I shall give in detail, because it was the cause of a complete revolution in my mind concerning the treatment of such cases, and because it may serve as an epitome of nearly all that could be told concerning these cases up to the time of its occurrence.

In the summer of 1881 I was asked by Mr. Hallwright to see with him in consultation a patient who had arrived by train from London in a condition of serious illness, that illness having been diagnosed by Mr. Hallwright as probably hæmorrhage into the peritoneal cavity from a ruptured tubal pregnancy. The patient was blanched and collapsed, the uterus was fixed by a doughy mass in the pelvis, and there was clearly a considerable amount of effusion in the peritoneum, but no distinct tumour could be felt above, and I agreed with Mr. Hallwright as to the nature of the lesion. This gentleman made the bold suggestion that I should open the abdomen and remove the ruptured tube. The suggestion staggered me, and I am ashamed to have to say I did not receive it favourably. I saw the patient again in consultation with Mr. Hallwright and Dr. James Johnson, and again I declined to act upon Mr. Hallwright's request, and a further access of [illegible] the patient. A post-mortem examination revealed the perfect accuracy of the diagnosis. I carefully injected the specimen which was removed, and I found that if I had tied the broad ligament and removed the ruptured tube I should have completely arrested the hæmorrhage, and I now believe that had I done this the patient's life would have been saved.

During the twenty years which had elapsed between this case and the first I have mentioned I had seen at least twenty-three other cases of a similar kind, and therefore I can entirely confirm what M. Goupil says of these cases to this effect: "So frequent is the occurrence of intra-pelvic" (and by this he means the true or intra-peritoneal) "hæmatocele, that I have made an analysis of forty-two of my cases which are irrefutable as to their diagnosis." He gives as the causes of these cases: 1. Hæmorrhage caused by the rupture of dilated utero-ovarian veins. 2. Hæmorrhage from rupture of the ovary. 3. Hæmorrhage caused by rupture of the Fallopian tube. 4. Hæmorrhage from the fœtal cyst itself having ruptured; and he says, "the largest number of cases fell under the last head." 5. Hæmorrhage within the fœtal cyst. Probably now M. Goupil would group the last three causes under one head—at least, I certainly should. At another place he says that ruptured tubal pregnancies are very common; for, according to Nonat, Baudelocque saw five examples in three months, and I know that anyone who makes a research in our serial literature will find them in abundance. The final argument as to their not being so rare as our text-books seem to assert is the fact that between January, 1883, and July, 1886, I operated upon twenty-five cases, and succeeded in saving twenty-four of them—a very striking contrast to the old plan of letting them alone to die. I have never seen a case of suspected rupture, or one in which we suspected extra-peritoneal effusion of blood, recover. As to the causes of intra-peritoneal hæmorrhage, I can only speak of two from personal experience; the first, and by far the more common, being ruptured tubal pregnancy. The second is hæmorrhage from some torn adhesions or badly tied vessel after an abdominal section. Thus I tied the pedicle of one ovarian tumour with catgut, and the patient died on the fourth day after the operation. I found a large intra-peritoneal hæmatocele due to the digestion and loosening of the ligature. In searching the literature of this question, I have found one case due to the rupture of an aneurysm of the cœliac axis, and a large number of cases having a traumatic origin, chiefly from rupture of the liver. Bernutz and Goupil have collected a few instances due to rupture of dilated uterine and ovarian veins, not connected with pregnancy; also two cases of rupture of the ovary in pregnancy. But everywhere the evidence is overwhelming that the most fertile source of this most fatal accident is rupture of a Fallopian tube dilated by a fertilised ovum. In very many of these cases a feature of great interest is the fact that the first attack of hæmorrhage is not fatal, and that the records yield incontestable evidence that it may require the repeated occurrence of bleeding to bring about the fatal issue. In some these attacks of hæmorrhage seem to have been separated by long intervals. Thus one case recorded as having occurred in the Maison d'Accouchement in 1816, where the history makes it evident that the tubal rupture occurred at the usual time, in the third month; the fatal hæmorrhage did not occur till the sixth month of extra-uterine gestation. In this case the fœtus was found, so that there could be no doubt as to the nature of the case.

But in some of the instances recorded by Bernutz and Goupil themselves—and I prefer their facts to all others, being, as they are, so carefully sifted and so free from any effort to theorise—it seems to me that the history was that of tubal rupture, repeated hæmorrhage, absorption of the gelatinous fœtus, and final death from hæmorrhage; so that when the post-mortem was made, the absence of a fœtus, which the authors note, blinded them to the real nature of the case. That the fœtus may disappear by absorption is made certain by my own experience. I have removed it only twice in my twenty-five cases, though I have found the placenta in every one. Thus Case 32 in the work of Bernutz and Goupil is an instance of fatal intra-peritoneal hæmatocele due to a ruptured Fallopian tube, which was distended by a tumour the size of a pigeon's egg. I have no doubt that a microscopic examination of that tumour would have shown it to have been a placenta. I think that this explanation applied to many of the carefully recorded cases of these distinguished French authors, in which the details given would incline us to characterise them as

being identical with that which was the subject of the recent trial at Liverpool. There are half-a-dozen cases in Bernutz's book which are identical with that case, except that they were all fatal, whereas the Liverpool case was successful. That woman's peritoneum was occupied by a quantity of blood-clot and blood-serum so great that it could be recognised by palpation before the operation. One of the Fallopian tubes was the source of the hæmorrhage, because it had a quantity of blood and blood-clot in it when removed. Here is a case almost identical, taken originally from THE LANCET of 1848: "A woman aged twenty-eight was suffering from rheumatism, when she was suddenly seized with nausea, vomiting, and pain in the right side of the abdomen; her face became anxious and pallid, the pulse imperceptible, the extremities cold, and the respiration oppressed; in short, collapse was complete, and she died in twenty-four hours, evidently from internal hæmorrhage. On opening the abdomen a quantity of blood was seen, but no rupture of any of the viscera could be detected. In the pelvis a clot was found in the left Fallopian tube. On separating the uterus, its cavity was filled with muco-sanguineous fluid and lined with a decidual membrane. The left tube contained a clot of blood the size of an almond. About an inch from the uterus at the upper part of this tumour was a rent, and within a small sac, so compressed and deformed by the clot that it was impossible to say whether or not it was an ovum. The left ovary was the size of an apple, filled with blood and ruptured."

Another case, on the authority of Dr. Tilt, is given by Bernutz at page 196:—"A multipara, aged thirty-seven, was seized with lumbar pain; the menses were four days late; the left hypogastric region became tender, and soon tympanites and vomiting followed. She succumbed in ten days. On post-mortem examination there was general peritonitis; a large clot of blood filled the left iliac fossa and pelvic cavity; the uterus was normal in size and the appendages on the right side healthy; the left half of the uterus and its appendages were larger and more distended than the right; the Fallopian tube midway was the size of a nut; a probe introduced at the fimbriated extremity passed into a cavity in the centre of the clot, which dilated that portion of the tube."

Another, on page 197, is to the same effect:—"On post-mortem examination all the abdominal organs were observed to be quite healthy, but very bloodless. In the pelvis a large quantity of blood was discovered, clotty and fluid. After careful examination of the principal bloodvessels, arterial and venous, without discovering anything abnormal, the uterus was examined, together with its appendages, and the source of the hæmorrhage was soon apparent, a small rupture of the right Fallopian tube being discovered at about half an inch from its distal extremity; blood was oozing from it, and it was evident that this was the seat of the bleeding; the tube itself was also a good deal enlarged."

Dr. Goodell also gives a fatal case where a death occurred from about eight pounds of blood being lost from the Fallopian tube, though there was no evidence of a tubal pregnancy.

Case 11, given by Bernutz (p. 208), is extremely instructive, because it is a fatal case of hæmorrhage from the Fallopian tube in a young woman aged twenty-two, due apparently to measles. "On post-mortem examination hæmorrhage was found to have proceeded from the left Fallopian tube, which was distended to the size of the index finger, and containing about two ounces of blood, partly fluid, partly coagulated, and through the abdominal orifice as much as sixteen ounces of blood had escaped into the pelvis. These samples of hæmatocele, occurring in rubeola, scarlatina, and variola, demonstrate that this accident may occur in any severe fever."

Finally, I wish to refer you to a case originally contributed to the *London and Edinburgh Monthly Journal* for 1841, because it establishes beyond all doubt that fatal hæmorrhage can occur from the Fallopian tube into the peritoneum under circumstances when the occurrence of rupture of the tube by an ovum is out of the question. An illustration of the tube is given. "A large quantity of blood was effused into the abdomen and pelvis, mostly coagulated but partly fluid. At first it was impossible to say whence all this blood came, but on examining the pelvic viscera solid coagula was observed protruding from the open orifices of the Fallopian tubes. The tubes themselves were filled with blood and distended at a short distance from the uterus up to the distal extremity. The condition of the parts is very well shown in the accompanying sketch, which represents the serious state of one of the tubes and the appearance of the clot attached; the latter has a sort of lobulated appearance, produced by the constrictions exerted upon it in its passage along the tube. The other tube was the same. The greater part of the blood found in the pelvis escaped from the tubes no doubt in a fluid state, but that which was attached to the tubes was coagulated before it left the canal, as is evident from its shape."

Concerning the prognosis of such cases Goupil says: "It is but too true, I fear, that we are authorised in saying that all the cases of intra-peritoneal hæmorrhage arising from extra-uterine pregnancy end in death—in fact, all the cases that I have quoted have terminated in death; generally it has taken place in a few hours or days, and though death has been delayed for six months (as in the case already quoted) it is wholly exceptional." This was absolutely true in my own experience, till I was emboldened—shall I say till I was shamed by Dr. Hallwright's cases?—to open the abdomen and save their lives.

We come, then, to the following conclusions: That in the great majority of cases of extra-peritoneal hæmatocele the disease may be left alone, being rarely fatal, and that it is to be interfered with only when suppuration has occurred. That, on the contrary, intra-peritoneal hæmatocele is fatal with such almost uniform certainty that so soon as it is suspected the abdomen must be opened and the hæmorrhage arrested. In the overwhelming majority of cases the source of the hæmatocele will be found in the broad ligament, and then it can be dealt with, and with every prospect of success. If anyone objects to this, I appeal again to the canon of surgery, which is of uniform application. For surgical hæmorrhage cut down and tie the bleeding point; if a big branch of the femoral artery were bleeding, my colleagues who deal in such cases would cut down and tie it. Why should Poupart's ligament be a line of demarcation within which this surgical writ will not run? Why should my friend Dr. —— be allowed to do to the external iliac artery what I am prohibited from doing to the internal iliac division? Indeed, at page 202 of Bernutz and Goupil's work they assert this principle: "The indication in such a case is plain—we must stop the hæmorrhage."

MASKED HEART DISEASE.[1]

BY W. AINSLIE HOLLIS, M.D., F.R.C.P.,
PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

"MEN observe when things hit, and not when they miss," says Bacon; and medical men are no exception to the rule. Much, however, may be learnt by the leisurely reconsideration of errors in bedside investigation. With this view I propose to take for my text certain cases of heart disease, in which necropsies have subsequently shown the imperfections of the clinical diagnoses. With our present aids to the proper investigation of disease, the various lesions of the heart which are commonly met with in practice can be in most instances differentiated with considerable accuracy. There will nevertheless remain cases that, from causes I shall hereafter recapitulate, may be overlooked or mistaken by the most careful observer.

Heart disease may be masked in a patient by one of the following reasons:—1. The conventional signs of disease of the organ may be altogether absent. 2. The auscultatory or other evidences of cardiac disorder may point to lesions other than those actually present. 3. Finally, the signs of heart disease may be so masked or obliterated by urgent local symptoms developed elsewhere as to be overlooked during the life of the patient. I shall not attempt to assign too closely under any one of these headings the causes of a faulty diagnosis in the cases I shall hereafter mention. In practice, two or more of these reasons will generally be found to operate conjointly in the production of the error. Whilst classifying the cases under one or other of the above divisions, let it therefore be understood that I have

[1] Read before the Brighton Medico-Chirurgical Society, Feb. 1886.

only selected the most prominent cause of the oversight in each instance.

Pathologists and physicians generally admit that there are many serious cardiac lesions which with our present lights must remain conjectural during the patient's life. According to Dr. Fagge,[2] in cases of cerebral hæmorrhage enormous *hypertrophy of the heart* may occur without any clinical evidences of such a condition. The organ seems to bury itself within the hollow of the left lung, and the area of dulness is consequently not increased. I have met with several cases of considerable enlargement of the heart which were unnoticed at the bedside, and I shall refer to some of them subsequently. It seems probable that several causes may operate to mask this enlargement during life. *Fibroid disease of the heart* is also frequently unaccompanied by any distinguishable signs of cardiac incapacity. The same author states that in three of the twenty-seven cases he had collected the patient died of some other cause. *Aneurysm of the heart* is seldom diagnosed clinically; and the symptoms of true *fatty degeneration* are very obscure.[3] It may be doubtless assumed that a patient who suffers from faintness, dyspnœa, and lividity, who has a weak, irregular pulse, and in whom there is an indistinctness of the first cardiac sound, may have this lesion. There will nevertheless remain a large percentage of sudden deaths from fatty degeneration of the heart wherein the cardiac changes were unsuspected until they were revealed at the necropsy. Finally, *adherent pericardium* may exist without being detected by any definite physical signs.[4] I shall here narrate a case under my care:—

S. W—— became an in-patient in 1883. He then suffered from orthopnœa and sickness. His pulse was extremely rapid and irregular. On examining the chest the area of cardiac dulness was found to be greatly increased downwards and to the left. A blowing systolic murmur was heard at the apex, and a loud clanging sound at the base over the aortic valves. There was a history of three attacks of acute rheumatism. A fortnight after admission he died. A post-mortem examination showed numerous old adhesions in the pleural cavities, especially the right; and a thin firmly adherent pericardium over the anterior and lateral walls of the heart. There was an enormous heart, weighing 30 oz. All its cavities were dilated, particularly the left, which were also hypertrophied. The mitral and aortic valves were thickened and flexible, but there was no vegetations. Both the calibre of the aorta and that of the pulmonary artery were greater than natural. The semilunar valves of the former, however, were apparently adequately enlarged, and it was doubtful whether there had been any incompetence during life. In this case, I acknowledge that my diagnosis was in many respects at fault. The pericardial adhesions were quite unsuspected by me whilst the sufferer was alive. Upon carefully reconsidering the symptoms of the case by the after-light cast upon them at the necropsy, I think the adherent pericardium was really the starting-point of all my patient's subsequent cardiac troubles. The heart, hampered in its action by being glued, as it were, to the anterior walls of the chest, at a time when it is probable that its walls were weakened by the existence of some myocarditis, was unable to carry on the work of the circulation as it had previously done; dilatation and compensatory hypertrophy accordingly followed closely upon the first lesion. These muscular changes were, I take it, a consequence of the pericardial adhesions, and not of any valvular deficiency, for the latter structures were flexible and smooth, and could not have offered any great impediment to the proper circulation of the blood through the various orifices. Towards the end of life there was probably regurgitation through the mitral orifice, but the aortic cusps seemed to be competent at the time of death.

Many authorities on heart disease (of whom Dr. Balfour is one) hold that pericardial adhesions do not produce hypertrophy—that when hypertrophy arises in such cases it is due to other, probably valvular, causes. In the case to which I have briefly alluded, it would seem to be a distortion of fact to fit a preconceived theory, if we are to believe that the great cardiac enlargement was due to the comparatively trifling valve disease observable. The frequency with which inflammation of the visceral layers of the pericardium are associated with a superficial myocarditis, and a consequent degeneration of the muscular substance of the heart may assist, as I before stated, in weakening the walls of the organ, and in paving the way to their future dilatation. I will narrate a second case:—

E. D——, a laundress, aged twenty-two, was admitted on September 4th, 1885, suffering from the effects of chill during convalescence from an attack of acute rheumatism two months previously. On the day following admission, the area of cardiac dulness was considerably increased, and for a few hours a rough friction sound was heard over the aortic valves, where the endocardial sounds were indistinctly audible. There was also evidence of fluid in both pleural cavities, and a blowing systolic murmur was heard over the scapular regions. Eight days afterwards the area of cardiac dulness was normal; the friction sound had disappeared, and the heart sounds were heard loudly over the front of the chest. The systolic murmur remained unchanged. It was now impossible to diagnose from the physical signs the previous pericardial inflammation. The patient, however, did not improve in health; the dyspnœa from which she had been suffering became more urgent, and she died two days subsequently. At the necropsy, besides pulmonary and pleural lesions, to which I need not here allude, both surfaces of the pericardium were everywhere coated with soft, rough lymph, which stripped off readily, leaving the serous membrane smooth and injected. There were also a few fibrous vegetations on the free edges of the mitral and aortic valves. The heart was not enlarged. In this case a universal pericarditis was present, and for two days before death there were absolutely no physical signs by which such a pathological condition could be diagnosed. The sudden disappearance of the abnormal sound over the præcordia was, I suppose, due to the more or less close agglutination of the two roughened surfaces of the pericardial sac during the last days of life, although the softness and slight consistency of the false membranes could only admit of a feeble cohesion between them.

The conventional evidences of one form of heart disorder are occasionally replaced by others associated usually with pathological changes of a different nature. Sietz[5] first noticed that the movements of an enlarged heart are sometimes attended with "to-and-fro" sounds simulating the rub of pericarditis, and this observation of his has been confirmed by Walshe and Fagge. I have not met with a case of this kind. It is, however, worth while to remember that these abnormal rubbing sounds may exist without inflammation of the serous membrane. I shall allude to the possible etiology of this phenomenon hereafter. Amongst the cases of which I have notes there are two I shall briefly notice in connexion with this division of my paper. They are both cases of mitral stenosis of the so-called "button-hole" lesion.

E. R——, aged thirty-three, a single woman, was an in-patient suffering from jaundice due to impacted gall-stones. There was also a history of old heart disease. On admission, nineteen days before her death, the heart's apex was three-quarters of an inch inside left nipple vertical. Action rapid and irregular. No murmur. These signs continued the same until death. At the necropsy the heart weighed 18 oz. The left cavities were especially dilated and hypertrophied. The mitral orifice was greatly contracted, and the valves thickened with soft easily detached vegetations along the free edges. The aortic valves were competent. A tuft of vegetations was attached to the ventricular surface of each corpus Arantii. No ulcerations of the walls of the ventricles or of the cusps. The valves were not thickened. Muscular tissue somewhat soft.

The other case was that of a woman about fifty, who was admitted with right hemiplegia. The heart's action was extremely irregular and rapid. There were no murmurs, and no definite signs of enlargement. The necropsy, a few days afterwards, showed hæmorrhage into the basal ganglia, and a well-marked "button-hole" mitral valve: the opening in its midst scarcely admitted a finger-tip. I have unfortunately mislaid the notes of this case, and I can only speak from memory. The facts, as far as they go, may, however, be accepted as true.

In both cases great stenosis of the mitral orifice existed without this condition of the valves giving rise to any præ-systolic or other murmur. The only symptom of importance common to the two cases was the rapid and irregular action of the heart. The condition of the patients, who were both extremely feeble at the time of admission, may have assisted in modifying the physical signs.

[5] Deut. Arch., xi., xii.

It often happens in practice that the clinical evidences of heart disease are masked or hidden by the conspicuous break-down of some neighbouring organs. The lungs are the organs which most frequently produce this complication. I have notes of three cases of hypertrophy and dilatation of the left cavities, in which no definite signs of such a condition were noticed during life.[6] This so far agrees with what Dr. Fagge *(vide supra)* has written on the subject. The only symptom I can find common to them all was dyspnœa—suffocating attacks of shortness of breath,—which came on with varying frequency for several days before death. In all the cases there was a considerable quantity of fluid in the pleural cavities, and the lung tissue was collapsed to a greater or less extent. (In one case a portion of the right lung was "carnified.")

The generally accepted doctrine as to the etiology of dyspnœa in such cases is ably expounded by the late Dr. Fagge.[7] In enlargement of the left heart slight excitement or exertion on the part of the patient will produce an altogether disproportionate increase in the rate of the pulse, with at the same time a sensation of dyspnœa. Dr. Fagge explains these peculiarities as follows:—"In spite of its augmented frequency, the heart, after all, fails to forward the blood through its left chambers with needful rapidity; there is therefore an accumulation in the pulmonary vessels, and the right ventricle has to make increased efforts to propel its contents onwards. And as the result is a state of the pulmonary circulation identical with that which is produced in other cases by a deficient supply of air to the lungs, it is not surprising that the same feeling of shortness of breath is experienced." This explanation implies that the dyspnœa in these cases is associated with engorgement of the pulmonary vessels. I must take exception to this view, as one which is not applicable to two of the three cases I am here considering.

Physiologists assume, in calculating the work done by the heart, that in the healthy man the ventricles empty themselves of blood at each systole. We may probably accept their conclusions founded on this assumption when they deal with an organ of normal capacity. These data are, I think, erroneous when applied to an enlarged heart, especially when the enlargement is associated (as is mostly the case) with dilatation of the left ventricle. The solid contents of spheres vary directly as the cubes of their radii. If we take a distended heart cavity to roughly represent a sphere (the actual shape of the cavity does not greatly affect the result), we can readily understand how a very slight augmentation of its mean diameter will largely increase its capacity. For example, a ventricle with the capacity equal to the volume of a sphere of one-inch radius will contain, when distended, about four cubic inches of blood. If we now take a ventricle having a capacity equal to the volume of a sphere of two inches' radius, the contents of such a chamber would be upwards of thirty-three cubic inches; that is to say, the heart, if it emptied itself at each systole, in the former case would propel only one-eighth the quantity of blood that it would do under the latter circumstances. It must be within the experience of most of us to have frequently examined hearts the mean diameters of whose chambers, if not double their normal size, were at all events greatly increased. Now the carrying capacity of such dilating hearts increases at a far more rapid rate probably than their propelling power—that is, than any compensatory hypertrophy of the muscular walls would be capable of adequately dealing with. The overtaxed ventricles of such enlarged hearts never quite empty themselves. There follows a condition of engorgement, not of the lungs in the first place, but of the heart itself. If, as mostly happens, the left ventricle is the one smitten by disease, in spite of its thickened walls and its enlarged chamber, a less volume of blood would be probably driven through the aorta and systemic vessels than in health, and an anæmic condition of the body would be the result. In some instances I have no doubt there is regurgitation through the mitral orifice and pulmonary congestion; but I desire it to be understood that this is an accidental and not a necessary sequence. In two of the three cases of cardiac enlargement I have just alluded to the lungs were pale and bloodless; yet the patients both suffered dyspnœa before their deaths—a condition exaggerated by the presence of a considerable quantity of fluid in the pleural cavities, although we must possibly seek for its origin in the engorgement of the heart and the consequent withdrawal of so much blood from the general circulation. It is this chronic distension of the dilated heart in a normally-sized pericardial sac which is doubtless accountable for the pseudo-friction sound occasionally heard in such cases.

Brighton.

[6] One patient died of hæmorrhage into the pons Varolii and atheroma of the cerebral arteries; another, whose heart weighed 22 oz., had sarcoma of the left kidney; the third had contracted granular kidneys, with a heart weighing 20 oz.

TREATMENT OF UTERINE FIBRO-MYOMA.[1]

By J. KNOWSLEY THORNTON, M.B., C.M.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

BEFORE proceeding to the consideration of the surgical treatment of this common disease, I will say a few words about the medical and dietetic treatment, because, seeing as I do a large number of cases in consultation with my medical brethren, and of cases who come to me from them, for an opinion as to whether any active treatment is necessary or advisable, I am much impressed with the fact that a great many of the patients, who might lead comfortable lives if they were wisely guided as to their diet and general method of life, are allowed or advised to follow a course which makes them worse instead of better, and tends to bring them into the hands of the surgeon.

When a patient presents herself with a small or moderate sized tumour I always begin by asking the following questions: 1. Are you getting so much larger that you have to alter your clothes? 2. Do you suffer any inconvenience from your increased size? 3. Do you suffer pain generally or at the monthly periods? 4. Are the monthly periods regular as to time, and are they prolonged or excessive? 5. Is the action of the bowels or that of the kidneys or bladder interfered with; and are there pressure symptoms, such as swelling of the legs and feet? When these questions have been answered, I ask for a sketch of the usual diet and the habit as to stimulants, and then as to the amount of rest taken at the onset of the period and during the flow. Finally, I inquire whether any special medical treatment has been adopted. If the first three questions are answered in the negative, as they are in the great majority of cases, the chances are that, with a little good direction as to medicine, food, and drink, there will be little need to take into consideration any surgical treatment. Now, I find that in the great majority of cases the patient has been told that she must live well, and take plenty of wine, beer, or spirit, to make up for the free periods and support her strength. There cannot be a greater mistake. The disease, in its early stages always, and in its later stages generally, is found in patients who have a tendency to make flesh and blood fast, and if their alvine and urinary evacuations are carefully regulated, and they are advised to take red or butcher's meat sparingly, and live chiefly on fish, white meat, eggs, milk, and vegetables, and practically wear the "blue ribbon," or only take the smallest quantity of wine or weak spirit-and-water, when their digestion is aided by so doing, the disease will stand still, and their tumours give them little or no inconvenience. They should also be encouraged to take regular walking exercise in the intervals between the periods, but to remain if possible at perfect rest when they occur, and more especially during the congestion which precedes the flow. It is also a common practice to give ergot during the menstrual flow, and I believe it is a great error. The growth cannot then be starved by contraction of the uterine muscle, for it is by its physiological nerve stimulation abundantly supplied with blood, and at the most the flow is checked, which is nature's natural outlet for the increased blood-supply, and thus is increased the congestion upon which the growth feeds. The ergot should be given with some nux vomica, which aids its action, and with other vegetable bitters, which prevent it from disagreeing with the stomach, in the intervals between the periods, and a tonic contraction is kept up in the uterine muscular fibres which starves the growth. Then, again, it is a common practice to give these patients iron, because they are often anæmic from loss of blood. I believe this is just as harmful as giving them red meat and wine. Anyone who has watched and studied

[1] Read before the Cambridge Medical Society, June 5th, 1886.

many of these cases will see that iron, red meat, and wine are the things upon which fibro-myomata grow, flourish, and bleed most. It would occupy too much time to inquire thoroughly into the life-history of these growths, but I am convinced that the ovarian nerve stimulus, which finds its natural outlets in regular menstruation, married life, and maternity, are their great enemies; and if we argue back from these, it is easy to see why iron and meat, the blood-givers, and wine, the great stimulator of the circulation, feed and stimulate the nerve forces, which in the majority of these patients have not and cannot have their natural outlet, and so, like all forces which are excited only to waste, run riot in disease. I do not mean to say that all cases can be prevented from growing by such simple measures, but I do unhesitatingly say that all patients will be made more comfortable by strictly adhering to them, and the large majority will find that they can so effectually check the progress of the growths that they will elect rather thus to regulate their lives than face the serious risks of surgery. I frequently see a patient with a tumour growing fast with all sorts of pelvic pains and discomforts, and with hæmorrhage which threatens to become exhausting. I sketch out a line of treatment, especially dwelling upon the importance of avoiding stimulants and the excessive use of red meat, and advise her to see me again in a few months, saying that it will then be time enough to talk about surgery. When the time comes for the second consultation, the patient comes, not to talk about surgery, but to say how much better she is, and to ask for some further and perhaps more stringent and definite rules as to diet, or for some variation in the aperient or tonic.

In passing now to the surgical treatment of those cases which have gone beyond milder measures, when they first seek special advice, or which the milder measures have failed in, I propose to take as my text three cases which I have recently operated upon, because it is quite impossible to deal with the whole subject in one short paper, and these three cases illustrate in a remarkable manner some of the practical difficulties of diagnosis, and some of the most important pathological considerations.

The first case is one of a very rare class, in which sub-peritoneal and pedunculate tumours grow so fast as to cause marked emaciation, and clearly such cases are only amenable to surgical treatment, and that of the most prompt and radical kind. I have selected this and the other two cases about to be related because they equally illustrate the impossibility of always making an accurate diagnosis between uterine and ovarian tumour, and because I hold that when such cases are met with immediate surgical treatment is the only proper course.

CASE I.—H. F——, single, aged thirty-six, was admitted into the Samaritan Free Hospital, under my care, on March 21st, 1886. She was markedly emaciated, especially about the face and bust, and said that she was losing flesh fast. For the last twelve months she had suffered from frequent attacks of bilious vomiting, with much flatulence and persistent constipation. She had never had any serious illness, and the lungs, heart, and kidneys were healthy. Her father died of phthisis at forty-one, and her only sister at twenty-one. Her mother, aged sixty-eight, was alive. One of her mother's brothers also died of phthisis. With the exception of the attacks of sickness, she had been in her usual health till two months before admission, when she noticed a lump in her abdomen, which fell over from side to side when she turned in bed. It increased rapidly in size after she first noticed it, and another similar lump soon appeared and also grew fast. Menstruation began at eleven and was always very free and accompanied by much pain till six or seven years back, when the pain and quantity both decreased, but the periods continued to be sufficiently copious and quite regular. On examining the abdomen, I found two large solid tumours: one lying rather to the right and in the lower abdomen; the other above it, entirely in the left side, and passing up under the ribs. Between the two, and somewhat to the left of the median line, there was a third small hard body of irregular outline, which I believed to be the uterus, and the use of the sound verified this opinion. The cervix was found by vaginal examination to be small and soft and high up on the left side. The pouch of Douglas was occupied by a hard rounded mass, which was evidently the lower part of the tumour in the right side of the abdomen. Looking to the position of the two tumours, their relations to the uterine body, the menstrual history, and their rapid growth, which was coincident with emaciation, I came to the conclusion that they were solid ovarian tumours. On March 24th I made the usual median incision and found that the two large growths were pedunculated fibro-myomata, that there was a third similar growth between them, and that the body of the uterus was covered with other small growths. Both ovaries were large, but fairly healthy. I at once decided to perform hysterectomy, as I could include the whole mass in the wire of Koeberlé's serré-nœud, leaving no tied stumps in the peritoneum; and when this can be done complete supra-vaginal hysterectomy is an easier and safer operation than the removal of outgrowths with vascular pedicles, which have to be ligatured and returned, together with the stumps of the ovaries and tubes, which it is necessary to remove in a case of the kind in order to stop the growth of the smaller tumours on the uterine body. The mass when removed weighed just under 7 lb. The patient, who was a nervous and excitable woman, had a temperature of 103°, with a pulse of 108, at the morning visit on the day after the operation, but it fell at once when some pounded ice was applied to the head in a piece of mackintosh, and she made an uninterrupted recovery.

In this case I am certain that an absolute diagnosis was impossible until the abdomen was opened; and though I did not exclude from my diagnosis the possibility of the tumours being fibro-myomata, their general characters, positions, and rapid growth made it more probable that they were solid ovarian sarcomata. This leads me into a short digression from the proper subject of my paper for the purpose of discussing a most important practical point. I have long been in doubt whether it is right to operate upon solid ovarian sarcoma, because, if the operation is immediately successful, the patient is nearly certain to die with recurrent sarcomata in the glands and in various parts of the body in from twelve to fifteen months. Of course it is impossible to say whether life would be more prolonged if the original tumour were left alone; but I fancy not, and that, on the whole, the suffering would be greater with this enormous abdominal mass present. It was not this consideration, however, which turned the balance in the case just narrated in favour of operation, but the fact that, among many recurrent cases (which can be consulted in my published ovariotomy tables), I have one signal success in the case of a young married lady, who was almost in a dying state when I operated, and from whom I removed a large brain-like sarcoma of one ovary, separating extensive adhesions which involved the other ovary. She had two girls before the operation, a third within two years, and quite recently, on the sixth anniversary of the operation, she sent me the photograph of a fine baby boy, who is the only male heir to his father's name, and whose advent had long been keenly desired; one such success makes up for many sad failures, and now the instance I have recorded is another encouragement to operate in these cases, for it would have been a terrible thing had I left this poor woman to perish, believing the tumours were ovarian sarcomata, when they were simple fibro-myomata and radically curable.

The second case which I am about to record is another example of the impossibility of certain diagnosis in some cases, and it again carries me beyond my subject; but the lessons it teaches are so bound up with it that I feel that no apology is necessary for relating it.

CASE 2.—E. A. J——, aged forty-five, married, and mother of one child twenty-four years of age, was admitted into the Samaritan Hospital, under my care, on April 3rd, 1886. She was not emaciated, but had a very sallow, unhealthy appearance. She had suffered for some years from sickness, flatulence, constipation, and pain after food. The heart and lungs were healthy, but the kidneys were daily secreting from twenty to thirty ounces of pale, highly albuminous urine, with a specific gravity of 1010, and she had for the last three years been unable to empty the bladder without the aid of manual pressure over the lower abdomen. She had married at the age of nineteen, and had one child; then had been a widow from twenty-one to twenty-nine; subsequently she married again, and had a miscarriage. She was regular after this till two years before admission, when coloured discharge became almost constant, and so continued. The father's family was phthisical; the mother was living, aged seventy-seven; and six of her own brothers and sisters had died, many of them of phthisis. She had had a lump in her abdomen for fourteen years; it was small and hard at first, and to the right of the median line; its growth had been very irregular—fits of rapid increase, followed by complete arrest. When growing fast it caused

much pain, and she had often been laid up for months at a time with the pain. Nine years ago she consulted one of the most distinguished authorities, and was told to wait for the menopause; and in October, 1885, she again consulted him, and the same advice was given. She was keenly anxious for operation, because of the attacks of pain and the increasing renal and bladder trouble. I found the abdomen occupied by a large irregularly-lobed tumour, with the bladder drawn up on its anterior surface; the tumour evidently contained a large quantity of fluid. Vaginal examination revealed a large soft fluctuant swelling pressing down between the bladder and cervix, so as to almost obliterate the latter, and a harder mass behind the os. The sound passed a little over three inches, and apparently into the centre of the mass, for the slightest touch on the abdominal swelling at once moved its handle. Looking to the long history, the evident opinion of the authority mentioned above, and the vaginal relations, I came to the conclusion that it was an old fibro-myoma which had become cystic; and as these tumours usually then grow very rapidly, and are quite as dangerous to life as the ovarian cysts, I had no hesitation in assenting to her wish that it should be removed, though I was fully prepared for a serious operation, and was very anxious as to the behaviour of the evidently damaged kidneys. I operated upon the 7th of April, and, after working hard for three hours and a half, succeeded in removing the greater part of what I have no doubt was a papillomatous cyst of the right ovary embedded in the broad ligament, as they so often are, and united by firm fibrous tissue to all the neighbouring organs, the adhesions having become denser and denser with the repeated attacks of pain (? peritonitis), and the uterus and bladder having been drawn out over the tumour, so that I had to remove the former and peel back the latter. In the course of the operation I tied both uterine arteries (the first time I have ever knowingly ligatured them), and exposed several inches of the right ureter, distended with urine. I was unable entirely to remove the cyst growing between the bladder and cervix, and this brought about a fatal result, for it filled gradually with ovarian fluid and blood; the mixture putrefied, and just when I thought she had got over her dangers, it was suddenly discharged into the peritoneum during the first action of the bowels on the sixth day, and she collapsed and died within an hour.

Here, again, we have a case evidently difficult to distinguish from a fibro-myoma in its early growth, and I am sure quite impossible to distinguish from a fibro-cyst of the uterus at the time it came under my care. I have operated upon many of these cases of ovarian or other cysts embedded in the broad ligament and without a pedicle, and though their enucleation requires care and is tedious, they usually recover well if only they are taken in time—i.e., while their connexions are mere loose cellular tissue; and I have no doubt that this poor woman might have been saved many years of misery, ending in a sudden death, and I the misfortune of an unsuccessful case, if only she had been lucky enough to fall into the hands of someone courageous enough to attack a somewhat doubtful case. The kidneys threatened to cease secreting for the first few days after the operation, and then, as if rejoicing in the unaccustomed freedom from obstruction, poured out an abundance of fairly healthy urine with a much-increased specific gravity; and while I was welcoming this new feature of hope the final catastrophe occurred. It is a combination of hysterectomy with incomplete ovariotomy, and, like a good many operations in the present practice of abdominal surgery, very difficult to classify for statistical purposes. It should be borne in mind that cases like this, though they may not kill the patient by rapid and excessive growth, may be slowly and surely doing so by pressing on and obstructing the ureters, and that the same pathological condition is brought about by many a large solid fibro-myoma, which gives apparently little inconvenience, and certainly neither causes severe pain nor danger from its size or from hæmorrhage—the three symptoms in these cases which have been over and over again insisted on as the only justification for operative interference.

(To be concluded.)

AT an inquest held at Burton on the 15th inst. on the body of James Sproule Smythe, a surgeon, who for some time had been in practice in the town, and whose death occurred on the previous day from prussic acid, the jury returned a verdict of "Death from misadventure."

ON VICARIOUS BLEEDING FROM THE UNDER LIP,

WITH CASES, AND REMARKS ON THE MODERN TREATMENT OF HÆMORRHOIDS.

By ALEXANDER HARKIN, M.D., F.R.C.S.,
CONSULTING PHYSICIAN TO THE MATER INFIRMORUM HOSPITAL, BELFAST.

CASE 1.—Mrs. M——, aged thirty-eight years, of bilious temperament, sallow complexion, dark hair and eyes, the mother of six children, called on me early in March, 1885. Before her marriage she had suffered from hæmorrhoids, and during her first and subsequent pregnancies from hepatic congestion and occasional hæmorrhage from the bowels, which frequently gave me some anxiety on her account. Among other troubles, in 1880 she was prostrated with profuse hæmorrhage from a cluster of varicose veins connected with the left femoral vein and close to the knee-joint. On this occasion she presented every sign of debility and anæmia: blanched cheeks and lips, sunken features, compressible and feeble pulse, undue palpitation of the heart on the slightest exertion, continuous headache, and frequent vertigo. She attributed her exhaustion to a profuse bleeding from the left under lip, occurring at every meal, and generally continuing for ten minutes each time. On examination I found a slight abrasion at the junction of the epidermis with the lining membrane of the lip, about half the size of a threepenny coin, from which the blood flowed freely. Mrs. M—— had removed from my neighbourhood two years previously, and, as the hæmorrhage from the piles had again become troublesome, acting on the advice of a physician of experience, she entered the Royal Hospital, Belfast, in February, 1883, where soon after the offending growths were deligated by one of the attending surgeons to that institution. After her return home in April, she experienced complete relief for a short time only, irritation about the anus occurring occasionally, and now and then a slight discharge of blood from the nostrils; but in the following June her left lip became painful, and blood began to ooze from it once or twice in the week; the intervals then became gradually shorter, the drain occurring every day, and for many weeks before her visit to me the discharge reappeared at every meal, or when accidentally the lip was hurt. Having from previous lengthened experience acquired a thorough knowledge of the patient's constitution and requirements, I did not hesitate in adopting a plan of treatment. I ordered the immediate application of a blister, 8 in. by 4 in., for eight hours over the region of the liver, to be followed by cotton-wool dressing. On visiting Mrs. M—— next day, I was informed that from the moment free vesication was established all labial hæmorrhage had ceased, and a return of health began to be felt. I then prescribed the use of chlorate of potash and iron in liberal doses; her colour and bodily strength soon reappeared, her headache and vertigo troubled her no more, and, with the exception of an occasional feeling of pain at the seat of discharge in the lower lip, she has not had a recurrence of any of her former ailments. In January last she gave birth to a male child without any unusual trouble, and up to the present date (a period of two years and seven months) there has not been even the slightest sign of the hæmorrhage.

CASE 2.—Mrs. McD——, aged thirty-six years, mother of six children, sent for me on March 8th, 1886. I found her confined to bed, pallid and exhausted from a profuse discharge of blood from the rectum, which had continued for several days, having delayed from motives of delicacy to send for medical advice; the blood accompanied every evacuation, and frequently after feeling a desire the motion consisted of blood alone, often to the amount of three or four ounces. On examination I found a fringe of external piles surrounding the aperture of the rectum, and inside the sphincter a number of knotty tubercles, from one of which red arterial blood flowed freely. In this, as in the former case, I immediately applied a blister over the region of the liver, and ordered as an adjuvant a mixture of tincture of perchloride of iron and chlorate of potash solution. The relief was immediate, and the patient very soon recovered her natural colour and strength, and was able to take out-door exercise. At the end of a fortnight [redacted] I was again called to the

case, and found that the bleeding had returned as freely as ever, with great mental and bodily depression. The relapse was due to the patient having unwisely stood behind a counter to assist her husband for ten hours on a previous day. As her friends had now become anxious on her behalf, I requested Dr. Walton Browne to see the patient with me. After recognising the nature of the ailment, we agreed to continue the hæmostatic medicine, and gave her a sedative enema at intervals. These remedies only gave her partial relief, and as the drain was still continuous and severe, at the request of the patient I reapplied the blister to the same place on March 28th. The remedy was again successful; all bleeding ceased, and has not made any reappearance up to the present date.

As bearing upon the etiology of these discharges, I wish to append the history of three recent cases in growing youths, very similar in character and cure.

On May 13th, 1885, I was asked to visit J. B——, a counter hand in a spirit store. He had been subject to free bleeding from the right nostril at short intervals for many weeks; he also suffered from severe headaches and constipated bowels; no history of piles. On examining the region of the liver, I found the organ tender on pressure and somewhat enlarged. I then applied the liquor epispasticus freely over the hepatic region, telling the young man that after five hours the hæmorrhage would permanently cease. I ordered some cholagogue medicine, at the same time giving him general directions as to diet. As I predicted, the hæmorrhage ceased, and now after the interval of more than a year it has not returned.

On the same day (May 13th), a young man, apprenticed to a chemist, was brought to me by his father, who stated that his son had suffered very much from indigestion and vertigo, and that he had been bleeding from the right nostril for many days. I had formerly treated his father for congestion of the liver due to excessive drinking. On looking at the abdominal region, I found an enlarged liver, with congested cutaneous veins traversing the abdominal surface over that organ. I applied the fluid blister, with the usual result—an immediate cessation of the epistaxis. The young man has since emigrated, but until the day of his departure, six months after, the cure had been complete.

On May 25th, 1885, J. S——, an in-door servant, suffering from profuse epistaxis from the left nostril, sought my advice. The bleeding had continued for six weeks, at intervals; it had first appeared at 6 A.M. and 9 A.M. daily, but latterly it observed no limits, coming on six or seven times in the twenty-four hours. On examination, I found a large and torpid liver; the patient had, besides, many of the subjective signs of the disease—disturbed sleep, headache, irritable temper, borborygmi, hardened fæces, high-coloured urine, depressed spirits, inability to rise in the morning, and drowsiness during the day. I applied the counter-irritant over the site of the disease, and with the result that the epistaxis yielded at once as well as the other objective and subjective symptoms of hepatic disorder. After an interval of more than a year he has continued well.

It is freely acknowledged by all writers on the pathology of hæmorrhoids that these adventitious bodies owe their existence chiefly to the congestion of a distant organ—the liver,—or to obstruction, from various causes, of the great portal vein, through which the venous blood from the abdominal viscera passes into the liver. Van Buren[1] has called attention to the fact "that these veins, including the hæmorrhoidal, are unprovided with valves, and that consequently, whenever the abdominal circulation is sluggish or obstructed, as by an overloaded colon, abdominal tumour, or congested liver, there is a strong tendency to stagnation in its lowermost tributary—the hæmorrhoidal vein. When a mass of dilated veins is thus frequently subjected to bruising in the act of defecation, it is liable to an attack of inflammation, the connecting tissues surrounding the veins becomes infiltrated with exudation, and the morbid anatomy of the hæmorrhoidal tumour is thus explained." With such a history of the genesis of piles, does it not appear strange that to a great extent the remedy is sought for, not in the removal or mitigation of their primary cause, but in their mechanical obliteration by ligature, by the actual cautery, or by the clamp? Yet such, unhappily, is too often the case; and what but serious injury must be the result, when this line of treatment is adopted in men with enlarged and indurated livers, with persistent engorgement of the portal system, and the circulation through the abdominal viscera almost completely obstructed? The fault, if such there be, is chargeable to the medical adviser, who, instead of proceeding upon physiological grounds and labouring to cure the disease by removing its cause, too often turns over his patients to the operating surgeon, and considers his responsibility at an end, when these erectile tumours, whether internal or external to the sphincter, are deligated in a scientific manner.

[1] Diseases of the Rectum, p. 18.

My first case clearly exemplifies the failure of merely surgical appliances in the absence of constitutional treatment, and the mistake of regarding a prominent symptom as the primary factor in the cycle of morbid phenomena. The violent suppression of a salutary discharge was soon followed by its re-establishment at the superior outlet of the digestive tract; and had similar methods been applied to its extinction on the labial outlet, we should doubtless have found that the nasal organ would in due course have protested, acccording to its wont, by profuse epistaxis, against the mere mechanical treatment of a systemic lesion. Would the doctrine of deligation be permissible in the latter case? The second example illustrates the advantage of counter-irritant and derivative treatment in immediately controlling and finally suppressing the hæmorrhoidal flux, and in this manner superseding the necessity for operative procedure, with its attendant dangers and discomforts.

The frequent occurrence of epistaxis in youth is evidently due to the excitement and hyperæmic condition of the liver and digestive organs during the period of activ' growth and the constant demands on its functional activity. The liver at this stage closely approximates to the condition in after-life, which is the causal factor in the development of piles, and as such is equally amenable to treatment in accordance with etiological principles; the derivative that cures the hæmorrhoidal flux as certainly puts an end to the epistaxis, the outcome of hepatic congestion. The cases related are but the types of many others in a lengthened experience. I have chosen them as being of recent occurrence, and as sufficiently removed from the date of treatment to test the validity and permanence of their cure.

My object in this paper is to enter my protest against the unsound principles upon which hæmorrhoids are so frequently treated, and the routine procedure adopted in the sudden suppression of a habitual discharge without sufficient attention to its remote cause.

Belfast.

AORTIC ANEURYSMAL DILATATION, RUPTURE, CAUSE, AND NECROPSY.

BY W. A. HOLMES, M.D., &c.

THE following is an account of a young man cut off in the prime of life through a defect, but aided by a sudden effort in spurts whilst rowing. His age was twenty-three years; he was apparently strong, healthy, and well built. He assisted his father in business, was not called upon to do sudden or heavy work, and was fond of rowing.

The following description of how the calamity occurred is culled chiefly from the coxwain's narrative of events:—In the evening, while practising for a rowing competition in a crew of four oarsmen and coxswain, they rowed for about half a mile at an ordinary pace, the deceased being No. 3 in the boat. They then had a sharp spin for 300 yards down the stream; shortly after this another for 200 yards; they then stopped, but for no alleged reason, for a few minutes, and then rowed leisurely. Again they put on another short spurt, and finally gently rowed to the boat-house. All this occupied about half an hour. During this period the unfortunate young fellow never showed any signs of fatigue or embarrassement, but when stepping from the boat he exhibited signs of fatigue, made apparent by his not helping to take the boat in as usual. He walked with the others into the dressing-room, but did not return at the time they did. This caused the coxswain to look for him, and he found him partaking of some brandy he had sent for. At the same time he complained of a bad attack of indigestion. The coxswain remarked to him, after he had finished dressing and come out of the room, "You don't look at all yourself," as he looked very heated and red in the face; the reverse was the case generally after exertion, when he looked white. He now got into a boat and was rowed home by the coxswain.

At the foot of the garden he got out of the boat and carried his bag into the house, changed his coat, returned to the boat, and sat in it while his friend took him for a row. When they had gone about a quarter of a mile, he remarked, "I feel just as if I had broken a bloodvessel inside," at the same time putting his hands by his side; then, almost instantly, without warning or without saying a word, he threw up his arms and fell to one side, partly leaning over the side of the boat. His friend replaced him in the boat, loosened the attire about the neck, and rowed him home. Apparently he had died at this time. Prior to the boating spree he had complained of indigestion, and he had not for some months partaken of any supper after a walk in consequence of the uncomfortable feeling he experienced during the attack of the said indigestion.

Necropsy.—Body well nourished and muscular. Arms from elbow to tips of fingers black, and lower extremities from knees to tips of toes of a similar colour. Post-mortem lividity in depending parts very marked. A frothy, black-looking, offensive fluid oozing from nostrils and mouth. No external marks of injury. Pupils equal, and widely dilated. After removing the sternum and cartilages of of the ribs, the pericardial sac was found much distended, and the prolongation of the parietal layer on to the aorta was visible, apparently pushing the superior vena cava to the right side. The pericardial bag and that part on the aorta was filled with a black congealed clot of blood and a small quantity of black fluid blood. The heart was entirely encircled with a clot about half an inch in thickness, the right auricle being much distended. The aorta was very much dilated; the measurement in circumference a little way about the base was 5¼ in., at the junction of the ascending and transverse parts 6¼ in., and at the middle of the transverse part 3¾ in. The aneurysmal dilatation was more marked posteriorly and on the right lateral surface of the ascending part; on the anterior surface in the same part, a little remote from the bend and passing up to the junction of the transverse part, was a curvilinear tear, ⅝ in. in extent, with a zigzag margin ⅜ in. from the base of the aorta. Another tear in the outer muscular coat was situate a little higher, but more to the right, it being an incomplete tear. The right auricle and pulmonary artery were filled with black fluid blood. The other chambers of the heart and aorta throughout were empty. Left ventricle very muscular. The stomach was much dilated, containing half a pint of green half-digested food, with much mucus (the colour due to spinach). Lungs, liver, spleen, and kidneys were black on section; very black fluid blood oozed out.

Remarks.—From the time the deceased gave up the rowing until the time he threw up his arms would be about three-quarters of an hour. The point of interest in this case is, When did the rupture occur? Did it occur during one of the spurts, or subsequent to one of them, permitting of rowing on another spurt, and finally to leisurely row in? He appeared to be fatigued when he first got out of the boat, felt what he called a bad attack of indigestion, was very red in the face, which was unusual for him, all of which tend to show that the rupture had occurred. But why such a large rupture in the aorta as ⅝ in. did not cause sudden death is a marvel. The brandy, through its stimulating effects on the endocardium, would cause more blood to be thrown forcibly into the aorta, and consequently more into the pericardial sac. Now, if this young man had not taken the brandy, but lain down and kept himself quiet, there might have been a possibility of his recovery, as I have seen a specimen where the aorta ruptured and the patient recovered and lived for months after, but died from a subsequent rupture; and other cases are on record. Another question is, Was death due to the coagulation of blood on the heart or to the impediment of the heart's action?

Barrow-in-Furness.

RED CROSS SOCIETY.—The National Society for Aid to the Sick and Wounded in War (British Red Cross Society) has received decorations of the Red Cross from H.H. the Prince Alexander, as President of the Bulgarian Red Cross Society, in favour of the Society's agents, Doctors Charles Fetherstonhaugh and Richard Lake, and Sister Henrietta Stewart (sent out by command of the Queen), in the late Servo-Bulgarian War, in recognition of their services to the sick and wounded in Bulgaria. A notification has also been received from the Foreign Office by each recipient that Her Majesty has been graciously pleased to grant them permission to accept and wear the decoration.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DIPHTHERIA: ITS TREATMENT.

By JAMES MERCER, M.R.C.S., L.R.C.P. Lond.

AT a time when so much is being written about outbreaks of diphtheria in the south, with its undue severity, it will be interesting to know the health in other parts of the metropolis. During the past twelve months it has been my share to treat no less than thirteen cases of diphtheria, with one death. No originality is claimed in the plan adopted by me, though it may somewhat startle a few at the large and frequent doses of certain drugs ordered. Briefly, my cases were treated, with the exception of very young children, by (1) internal treatment, (2) by emetics, (3) by gargles, and (4) hygienically.

1. Where the depression is marked, though there may only be the slightest indication of a certain questionable grey slough, with a moderate amount of elevation of temperature and glandular enlargement, a mixture (preceded by a gentle aperient) of the following should be ordered: solution of perchloride of iron, six drachms; dilute nitric acid, two drachms; glycerine, one ounce; water to six ounces; an ounce to be taken every two hours. After the lapse of a few hours patches may be noticed extending in certain directions, while the original patch or patches will appear somewhat shrivelled, the temperature and glandular enlargements probably increasing.

2. An emetic may now be used. Apomorphia acts in these cases most satisfactorily, from three to five minims promptly producing emesis in from one to three minutes. If now the ejected contents be examined portions of slough may be detected. The patient, though rather prostrate, will be much relieved of urgent dyspnœa. It is rarely necessary to repeat the apomorphia. The iron mixture is to be continued every second hour.

3. If the patient be intelligent and able to use a gargle, the following will be found most beneficial, establishing a healthy condition to the surface from those portions of the fauces and tonsils where the patches have been recently bared of membrane in the efforts of sickness produced by the apomorphia. The gargle should be made in this fashion:—In a six-ounce bottle place a drachm of chlorate of potash, add to it half a drachm of pure hydrochloric acid, and while the nascent chlorine gas is being generated fill the bottle with water, and direct that an ounce of the gargle should be used (the head being well thrown back) every third hour.

4. The patient's strength should be maintained by small and frequent quantities of milk and clear beef-tea unflavoured with pepper, salt, &c. Alcohol is urgently demanded, and may be given with a free hand and with much benefit should prostration be marked. It is absolutely imperative that the temperature should be uniform—say, 70° F., with a current of fresh air.

Drayton-park, N.

TWIN LABOUR COMPLICATED WITH RUPTURE OF LARGE VARICOSED LABIAL VEINS.

By AMBROSE ATKINSON, M.R.C.S.

SOME little time ago I attended Mrs. F——, aged thirty-nine, in her eighth confinement. Labour commenced about 8 P.M., though she had been poorly for over twenty-four hours. On examination a breech presentation was made out. After waiting some little time it came well down into the pelvis, and when near the outlet the right labium began to swell. The delivery was easy, but whilst separation was being effected the patient was seized with another very strong pain. On examination, made with difficulty, a second group of membranes could be felt, which I ruptured, and the patient obtained ease. This procedure, however, did not affect the tumour, which steadily increased to an alarming size. Another pain coming on, the tumour suddenly burst on its inner side, deluging the bed &c. Not caring to take the whole responsibility, I sent for Mr. Holmes

of Burmantofts, requesting him to bring the forceps, with the hope of seizing the presenting head. In the meantime, as hæmorrhage was freely going on, I made a firm pad of a napkin and held it to the parts, so as to effectually stop the bleeding. On Mr. Holmes's arrival he slipped the short forceps on to the second head, when the child was suddenly expelled, the injured part being at the same time firmly compressed. The placentæ were then easily disposed of. On examining the damage, it was found that the inner side of the labium was so torn that four fingers could be passed into the opening, which led to a cavity sufficiently large to hold the whole hand. The bleeding had now abated, so the cavity was filled with strips of lint well dusted with iodoform. Pressure being applied by means of a firm spica, the patient was left for the night. On the following morning opium was administered and the plugs were removed, very little bleeding occurring. The vagina was syringed out with perchloride lotion (1 in 3000), and an iodoform suppository placed well up into it; the wound was then dusted with iodoform. This was done twice a day for a week, the patient making a very good recovery. A piece of vein about three-quarters of an inch long, which lay across the wound, sloughed off about the fifth day, a little bleeding taking place. On questioning the patient about the vein, she told me, after all was over, that she had had a lump there for some time, which got larger towards night, but she did not think it worth noticing. The question is, supposing I had known about it before delivery, could anything have been done to save rupture?

Burmantofts.

AN INDIARUBBER CATHETER IN THE MALE BLADDER: SUCCESSFUL REMOVAL.

By HENRY O'NEILL, M.D., M.Ch.,
SURGEON TO THE BELFAST ROYAL HOSPITAL.

WM. M——, aged sixty-three years, farmer, near Belfast, suffered for the past three years from retention of urine due to enlargement of the prostate gland, which required him to use an indiarubber catheter. Whilst passing the catheter on the evening of June 6th, 1886, it accidentally slipped into the bladder. Being called in consultation with Drs. Clugston and McNinch, I found the patient had been suffering from complete retention of urine for thirteen hours and a half. Having placed the patient on his back and administered methylene from Junker's apparatus, I introduced into the bladder a small Thompson's lithotrite, and after searching carefully for some time, I succeeded in extracting the catheter, which was about nine inches long and in size about a No. 12. After its extraction, on drawing off the urine a small amount of blood was mixed with it. The bladder was carefully washed out with warm water, using Clover's suction-syringe. The patient was given one-tenth of a grain of morphia, and the next day a gentle saline aperient was administered. He had the urine drawn off regularly and the bladder washed out with solution of sulphocarbolate of soda (half a grain to the ounce) twice a day. A poultice of linseed-meal was applied over the hypogastrium and kept on for two days. Three days after the operation he was reported as improving, with no bad symptom, and at the end of nine days was going about his usual duties.

Belfast.

NOTE ON COCAINE.

BY GEORGE ELDER, M.D., C.M. Glas.

COCAINE is now so extensively used in minor surgery, and usually with such happy results, that an experience like one I had the other day will come upon most of us as a disagreeable surprise.

A minute preliminary to opening a superficial abscess, twelve injections of a freshly prepared 10 per cent. solution were made under the skin; and three or four minutes after-wards syncope supervened, followed by twitchings of the face, trembling of the jaw, coldness of the body, clammy perspiration, lividity of the face—in fact, all the appearances of impending death. The patient was several minutes in recovering consciousness, and during the remainder of the day he was very prostrate. Several similar occurrences have been recorded in ocular surgery from time to time, showing that cocaine is not the harmless drug generally supposed.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propriis collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. GEORGE'S HOSPITAL.

SUICIDAL PENETRATING WOUND OF THE NECK; RECOVERY; REMARKS.

(Under the care of Mr. PICK.)

WOUNDS of the front of the neck are the commonest of those met with in this region, and attended with so many dangers that it would take too much space to even enumerate them. In the following case the treatment adopted was most successful, the application of a stout silk ligature on each side being sufficient to keep in apposition the parts divided until firm union had taken place; this was no doubt much aided by the operation of laryngotomy. All danger of suffocation from the extension of local complications was thus prevented, and the patient enabled to breathe pure air. The introduction of a catheter into the œsophagus saved much difficulty in feeding the patient, more nutriment being introduced in this way than could otherwise have been given without great pain and considerable disturbance of the parts. In the majority of wounds of the anterior part of the neck it is not advisable to introduce sutures so as to close the wound; but in a case such as the one which we record, where a certain amount of antiseptic treatment can be applied and the smallest amount of disturbance of the parts is permitted, the introduction of sutures hastens the healing, and is certainly to be advised. For the following notes we are indebted to Mr. W. Bull, surgical registrar.

J. T——, aged forty, a night porter, had been a heavy drinker of beer for many years. There was gout on the father's side of the family, but no history of insanity. Latterly he had been much depressed, owing to having lost the securities for some money lent to a friend. He was found in a watercloset with his throat cut, lying in a pool of blood.

On admission, there was a wound four inches long, which commenced on the left side of the neck over the carotid sheath, and, passing across to the right side through the thyro-hyoid membrane, terminated close to the right carotid vessels. The incision passed through the epiglottis, the larger part of which was left attached to the base of the tongue, and, having completely divided the middle constrictor of the pharynx, had laid bare at one spot the vertebral column, so that the upper part of the pharynx was severed from the lower, and the larynx and trachea had receded towards the chest for fully an inch and a half. There was no hæmorrhage except some slight venous oozing. The house-surgeon, Mr. Page, brought together the divided edges of the middle constrictor with fine catgut sutures, having first passed a gum catheter through the mouth into the œsophagus. On temporary closure of the skin wound, intense dyspnœa came on, so as to endanger the man's life. A stout silk ligature was now passed on each side through the upper border of the thyroid cartilage below and the tissues surrounding the hyoid bone above, and then by gradually drawing them tight the larynx was raised to its proper position. The ends of the ligatures were left long, and were brought out at the corners of the skin wound. Laryngotomy was performed, and a silver tube introduced. The skin wound was united with silver sutures, and dressed with carbolised gauze. The patient was placed in a tent, the air of which was kept moist by a eucalyptus steam spray. The man was fed every four hours through the catheter. He passed a quiet night, but was a little restless next day. Owing to his attempting to bite through the catheter, it was thought advisable to remove it, and introduce one through the nose; this was more comfortable, and for twelve days he was fed entirely

through the nose. On the twelfth day the stout silk ligatures came away, and sufficient union had taken place to retain the larynx in its normal position. The power of deglutition returned, and the nasal tube was removed. Afterwards there was no trouble in swallowing. In a few more days the tracheotomy tube was removed, the original wound having nearly healed, the tent and spray were dispensed with, and the man was allowed to get up. For several days rapid improvement followed, but on the tenth day after the removal of the tracheotomy tube there was difficulty in breathing, which culminated in an attack of spasmodic dyspnœa. Fortunately this was not fatal, but it was deemed necessary to reintroduce the tube through the crico-thyroid space. After wearing this for a week he was able to leave it off for several hours at a time, being trained to this by closure of the tube with a cork, respiration taking place through an aperture in the upper convex surface of the tube. On June 26th he was made an out-patient, wearing a silver tube, and came up daily to be watched while it was removed. At the end of August he left the hospital, being able to breathe freely in the normal way. The only change noticeable was a slight huskiness in the voice.

Remarks by Mr. PICK.—It is seldom that the tissues of the neck are divided, with sufficient freedom to allow the weight of the lungs to cause retraction of the lower end of the air-tube towards the thorax. Dr. Gairdner (*Edin. Med. and Surg. Journ.*, vol. xvi. p. 353) has recorded a case in which, after division of the larynx and œsophagus through the crico-thyroid space, the cut extremities retracted from each other to the distance of at least three inches. Attempts to procure union of the divided larynx failed. The man recovered, and for the remainder of his life had a large fistulous opening through which he breathed, and took food by passing a tube into the lower end of the œsophagus. In subcutaneous rupture of the trachea a similar recession is met with. In the present case it will be seen that the larynx dropped an inch and a half towards the chest. The case is also of interest in the success which attended the attempt to procure union of the thyroid cartilage to the tissues around the hyoid bone, and the ultimate perfect recovery of the power of deglutition and normal respiration.

TOTTENHAM HOSPITAL.

STONE IN THE BLADDER; SUPRA-PUBIC LITHOTOMY; RECOVERY.

(Under the care of Dr. LICHTENBERG.)

FOR the following notes we are indebted to Mr. Lloyd G. Smith, M.B., house-surgeon.

Thomas A——, aged fifteen years, errand-boy, was admitted on October 29th, 1885, complaining of loss of flesh, frequent and painful micturition, with the passage of gravel and occasionally blood, nyeturia, and prolapsus ani. He has always had some amount of pain on micturition as long as he can remember, with pain at the end of the penis, which was relieved by pressure at that part. Three months previously he passed blood in the urine for the first time; and severe straining, with increase of pain on micturition, supervened. He had been treated at a dispensary for "debility," and he thinks the medicine prescribed relieved the pain for a time. Since then he has been in a union infirmary, where he was told he had a stone, but no treatment or examination of the bladder was attempted. The family history is good, and there is no history of any other illness. His surroundings at home have been uncomfortable, as, owing to the large family, the supply of food has frequently been insufficient—so much so that he at one time left home and attempted out-door work on a farm, and then went on the tramp, when he became so ill as to necessitate his removal to the union infirmary, as above mentioned, whence he returned home.

On admission he was in an emaciated condition; micturition was frequent and painful, and only accomplished in the erect attitude; the urine contained glairy strings of mucus and gravel, was alkaline, and passed involuntarily during sleep. On passing a sound, it at once struck a stone, and per rectum a calculus, apparently about an inch and a half long, was felt. The anus was prolapsed, but easily reducible.

On Nov. 5th chloroform was administered, and an incision three inches long made above the pubes in the middle line. After the bladder had been moderately distended with warm boric lotion, retained by means of an elastic ligature around the penis, the tissues were dissected aside down to the peritoneum, which was pushed up and held by the finger, and the bladder found lying somewhat deeply. An incision was made through its walls, and the stone seized, but found to be friable, and could not be removed until the incision in the bladder had been enlarged and the calculus pushed up by an assistant's finger in the rectum; it was then easily removed by means of dressing-forceps; some fragments and débris were also removed. The bladder wound was left open, and a T tube placed in the bladder, with a long end to pass into a vessel at the side of the patient. The abdominal wound was sutured with carbolised silk and a drainage-tube in its lower edge. The patient was laid on his side in bed with the end of the T tube projecting into a vessel, and his thighs &c. were well smeared with "pasta urinæ" to prevent excoriation from urine. The diet ordered was milk and beef-tea; the patient's position to be changed at intervals. The calculus removed was the shape of a kidney potato, consisted of uric acid in layers covered externally by a coating of mucus, and weighed seven drachms.

Nov. 6th.—The bladder was irrigated with warm boric lotion. He had slept after the administration of a quarter of a grain of morphia, in the form of a suppository. Urine passed freely, but not so much by the T tube as by the drainage-tube in the lower part of the wound. Glairy mucus passed with it.

8th.—The lower sutures in the abdominal wound were removed, and it was found united. The bladder was irrigated every day with warm boric lotion. Solids were added to the diet.

12th.—The T tube was removed from the bladder, when there was slight swelling and some tenderness around the wound. The temperature had since admission kept fluctuating, at times rising as high as 101° in the evening.

15th.—The remainder of the sutures in the abdominal wound were removed, and the diet was further increased.

19th.—The temperature rose to 103°, and in the evening he had a rigor. The tenderness and swelling around the wound had increased. A boric compress was applied to the wound, and frequently changed. The swelling gradually subsided after extending into the scrotum, and by the 21st the temperature had become normal, which continued until convalescence. Constipation occurred at times, which was treated by mild aperients and enemata. Since the operation the prolapsus ani had steadily diminished. Salicylate of soda in doses of ten grains was administered thrice daily to correct alkalinity of urine, and with some success.

On Dec. 3rd urine was passed per urethram, but continued to escape by the abdominal wound as well until the 12th, when the wound was healed throughout; the urine was then faintly acid. Subsequently a small sinus formed and became a fistula, through which drops of urine and mucus were discharged. This did not close until January, when he was discharged greatly improved in health, having gained in flesh to a surprising extent.

TORBAY HOSPITAL, TORQUAY.

TWO CASES OF LUPUS TREATED SUCCESSFULLY WITH IODOFORM; REMARKS.

FOR the following notes we are indebted to Mr. Guy Tyrrell, house-surgeon.

CASE 1.—Alfred R——, aged sixteen, was admitted to the hospital on Feb. 4th, 1884, suffering from lupus of the nose and lip. The disease had existed for eighteen months, and had already destroyed the lower half of the ala of the nose and almost the whole of the upper lip. The patient was ordered cod-liver oil, and the sore was dressed with an ointment consisting of one drachm of iodoform to one ounce of vaseline, plugs of lint covered with the ointment being inserted into each nostril. The sore immediately began to assume a healthy appearance and healed slowly but uninterruptedly, and the patient was discharged cured on July 29th.

CASE 2.—William V——, aged sixteen, was admitted on March 13th, 1886. The disease had existed for two years, and extended over nearly the same area, but the lip was not so deeply involved. The same treatment was adopted, and with an equally good result. The patient was discharged cured on August 3rd.

Remarks by Mr. TYRRELL.—I am induced to publish these cases as I do not know that this remedy has been tried before, not having seen it mentioned in any books; but the

results in these two cases were certainly most striking, and I think it worthy of a further trial, as it is certainly a less painful method than scraping or cauterisation.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Extra-uterine Gestation.—Three Hundred complete Cases of Ovariotomy.

THE first ordinary meeting of the session of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. A very valuable statistical paper by Mr. Knowsley Thornton occupied the greater part of the evening.

Dr. HENRY GERVIS read a case of Extra-uterine Gestation. It was that of a woman aged thirty-five, who was admitted into St. Thomas's Hospital on Nov. 19th, 1885. The patient ceased to menstruate on May 9th, and her pregnancy proceeded without incident until July, when she experienced severe pain in the abdomen, which continued until admission. In September she passed per vaginam a pint of "thick greenish fluid"; similar discharges continued at intervals until she came under observation. There had been no uterine hæmorrhage, but a piece of "skin" was said to have come away with the discharge on one occasion. On admission an ill-defined swelling was noticed in the hypogastric region, extending towards the right of the middle line; the lower segment of the uterus appeared expanded and fixed. A large quantity of offensive discharge, yellow in colour, was issuing from the vagina through the os uteri; this discharge was found to consist of broken-down muscular fibre and vegetable tissue. On December 14th she passed per vaginam the shaft of a fœtal tibia. On exploration the decomposing body of a small fœtus was found lying, as it were, transversely in the uterine cavity. It was tightly fixed in its position, and all attempts to extract it were in vain; slight hæmorrhage occurred during the operation, and the patient died on the following day. The details of the post-mortem were narrated. The great omentum and the intestines were adherent to the brim of the pelvis, and under this mass the remains of a partially disintegrated fœtus were found in the posterior half of the pelvis. Almost the whole of the posterior wall of the uterus had sloughed away. The author concluded with remarks on the case, and pointed out that he was unable to find any similar case of extra-uterine gestation occupying Douglas's pouch, communicating both with the uterine cavity and the small intestine.—Dr. C. H. F. ROUTH thought the diagnosis might have been made out more accurately earlier in the case. In cases of extra-uterine pregnancy the menstruation ceased from the very first, and returned after a few months, when pieces of decidua usually came away. A growing tumour not in the uterus coming on under such circumstances could only have been due to an extra-uterine pregnancy.—Dr. GERVIS said that the tumour was not a growing one when the case came into St. Thomas's Hospital. It was, as Dr. Routh suggested, a matter of opinion what means were employed for dilatation of the cervix uteri, but in this unique case the necropsy showed that the method of dilatation would not have affected the result.

Mr. KNOWSLEY THORNTON read a paper on Three Hundred additional Cases of complete Ovariotomy and Twenty Cases of Exploratory Operation. After a brief reference to 188 ovariotomies and 22 other cases of abdominal section previously brought before the Society, the author referred to certain alterations in the arrangement of the tables in the present series. A brief description was given of the treatment adopted in ordinary cases, and of the method of drainage in cases requiring it. Cases of hysterectomy, oöphorectomy, nephrectomy, splenectomy, hepatotomy, &c., were not included, as being better dealt with in separate papers. All the operations had been performed with full antiseptic precautions, but this question was not specially discussed. Septicæmia had not been quite banished, but much had been done in this direction, as shown by one consecutive series of 100 cases performed at the Samaritan Hospital without a death from septicæmia. A progressive decrease in mortality was shown, and a comparison given of the results obtained in this series with those published by some other leading operators. Adhesions, place of operation, age and condition of patient, removal of one or both ovaries, and weight of tumour as influencing mortality were discussed. The temperature and pulse columns were carefully examined and important facts noted, reference being made to Wunderlich's standard temperatures. The benefit of cold applications to the head and in the form of partial or complete wet packs was demonstrated. The influence of the onset of metrostaxis and of the appearance of "sweat rash" were referred to. Drainage was discussed. The speedy recurrence in cases in which solid sarcomata had been removed was pointed out, and also the serious after-mortality from malignant disease of peritoneum, &c. Avoidance of tapping and performance of early ovariotomy were strongly advocated in this latter connexion. The effects of the removal of both ovaries on menstruation were clearly demonstrated in the tables. Brief details of each fatal case were given. Full tables of all the cases, especially full in the exploratory series, and an analysis of the temperature columns, completed the paper.—Sir SPENCER WELLS said there were many remarkably interesting features in the paper. He observed that of the 320 cases there were only nine in which the Fallopian tubes were diseased. It was supposed that disease of these tubes was of extreme frequency. In his experience it was of rare occurrence. The fact that the mortality decreased as time went on should be borne in mind. In his own practice the mortality went down steadily from 30 in the early part of his practice to 10 per cent. in later years. Antiseptics had proved of great service. He had not used a drainage-tube primarily in ovariotomy since 1878. The tapping of simple cysts was, in his opinion, a safe procedure. They were not malignant. He had observed that tetanus tended to occur epidemically. It seemed at times as though "waves" of tetanus passed over the country in some particular direction. He congratulated Mr. Thornton on his magnificent success.—Mr. ALBAN DORAN referred to the tapping of broad-ligament cysts. His pathological experience supported Mr. Thornton's clinical contention, that tapping even apparently simple cysts was not a safe procedure. Perhaps one case in nine of apparent simple cysts was of papillomatous and malignant nature. Dr. Coblenz showed in Virchow's *Archiv* of 1880 that these papillomatous cysts were very frequent. Exploratory incision was less dangerous than tapping. Dr. HEYWOOD SMITH spoke of the value of the drainage-tube in certain cases where oozing of a grumous fluid occurs.—DR. W. S. PLAYFAIR said that the "spray" was not a necessary adjunct to antiseptic ovariotomy. He considered until the antiseptic system came into use that it was not safe to operate on cases of ovariotomy in general hospitals. In his belief the "spray" involved the complete and minute carrying out of antiseptic precautions. Hence its value. The free washing out of the peritoneum with water was a valuable procedure, and less irritating than the employment of sponges.—Dr. GERVIS said that the plan of washing out the peritoneum with water originated with the Americans, who even anticipated the Germans.—Dr. K. THORNTON, in reply, said that the employment of the ice cap and cold sponging for keeping the temperature within bounds was of great value, but antiseptics had greatly diminished their need. Drainage-tubes saved lives, and prevented discomfort and fever. But the tube should not be left in too long, lest it irritate the peritoneum, with the result that a chronic effusion is brought on that may cause flooding of the dressings. He was a great unbeliever in the value of tapping simple cysts. He doubted whether there was a large number of cures by this method. And the post-mortem records did not yield any evidence of the existence of cysts that had been so cured. He had never found the reopening of a wound with the insertion of a drainage-tube to be successful. He objected to the use of fanciful terms, as "grumous fluid," which could hardly mean anything more than a mixture of blood and serum. He was not a bigot in the matter of the spray, but it was a useful element; it kept everything about the wound constantly moist with an antiseptic material. He was prepared to admit that washing the wound out with water was very valuable. In cases of pyo-salpinx, where little particles of matter were lodged in various crevices and corners, the hot water broke up the particles into atoms that were easily absorbed or dispersed.

CLINICAL SOCIETY OF LONDON.

Removal of Scapula for Osteo-sarcoma.—Ligature of Large Arteries.

AN ordinary meeting of this Society was held on the 22nd inst., Mr. Sidney Jones, F.R.C.S., Vice-president, in the chair.

Mr. CHARTERS SYMONDS read a paper on a case of Removal of Entire Scapula for Osteo-sarcoma, in a man aged thirty-four, who remained well, and was shown at the Society, two years having elapsed since the operation. Six months before admission he fell and bruised his shoulder, attending for a month at the Croydon Hospital, where he was told he had ruptured a muscle. One month after the accident a swelling appeared, and from that time steadily advanced without pain. The inconvenience was due entirely to its size, the man being unable to do heavy work. When admitted he was healthy in other respects. To the dorsum of the scapula was attached a tumour measuring from nine to ten inches, and projecting five inches from the surface. It moved with the scapula, and did not appear quite to reach the glenoid cavity. The spine of the scapula could just be traced. On April 1st, 1884, the whole bone was removed except the acromion and coracoid processes. The usual transverse and vertical incisions were made, one flap only being reflected at a time. First the minor flap was dissected off, and the posterior border of the bone freed. Next the inferior angle was isolated, and then the anterior flap was reflected and the axillary border freed, the various muscles being divided. The deltoid and trapezius muscles were divided close to the spine of the scapula, and the superior border was freed. The growth was found to extend to the glenoid cavity, so after sawing off the acromion and coracoid processes, the capsule and the muscles covering it were severed. The whole mass was then raised from the chest, and the serratus magnus divided. The subclavian was compressed during the operation, and all the large vessels seized by two pairs of forceps before being divided. In this way little blood was lost. The same evening the man had an unexplained attack of dyspnœa which lasted twenty-four hours, and interfered with sleep. The temperature rose quickly, reaching its highest point—103·6°—on the fourth day, but instead of falling it passed into a hectic fever, which lasted till May 9th, and then suddenly ceased on the removal of the cause of suppuration—viz., the head of the humerus. Rapid recovery ensued. Another clinical feature of interest was œdema of the arm without redness, and with no special fever. This was attributed to thrombosis of the axillary vein, but as it disappeared within a few days of the removal of the head of the bone, some other explanation seemed called for. Mr. Symonds drew attention to the fact that the continued suppuration appeared to be due entirely to the cartilage covering the head of the humerus. This structure was found in a suppurating state, and was being thrown off by granulating tissue, and the moment the entire surface was removed recovery began, and was so rapid that within a few days the patient was up and the parts healed, the man gaining flesh within three weeks. The complication was attributed previously to traumatic fever, which determined suppuration in the wound, and that this, involving the joint structures, the cartilage acting like a foreign body, maintained the suppuration. Mr. Symonds said he now always carefully removed all cartilage in operations involving joints. The man was shown to the Society two years and a half after the operation and had a useful arm. He could do much of the lighter work of his trade, that of a carpenter, being able to drive nails and screws and use a plane. The rhomboid muscle acted well, having obtained a partial attachment, so that both shoulders could be thrown back. He could rotate the shoulder and carry it backwards and forwards, but was unable to raise it from the side. The tumour was a hard osteo-sarcoma, having a basis composed largely of fibrous tissue.—Mr. R. W. PARKER thought that in the majority of cases of malignant tumours it would be better to remove the entire bone. He had removed the scapula twice in children for sarcoma; but the growth recurred. In a child aged thirteen years the right patella was the seat of a sarcoma; no recurrence had taken place after the lapse of nine months. This was the most successful result that he had had in the surgical treatment of sarcomata of bone in children. The success was attributed to its being possible to remove the whole bone.—Mr. CHARTERS SYMONDS explained, in answer to Mr. S. Jones, that the tumour was one of the less malignant forms of sarcoma.—Mr. H. T. BUTLIN referred to a paper on Removal of the Scapula contributed by M. Poinsot to the *Revue de Chirurgie*. Altogether forty cases were collected, some of caries and necrosis, but the majority of tumours. Only two of the patients died as the direct result of the operation. In not a single instance was the operation successful when it was performed for pure sarcoma. The only thoroughly successful case was one of very doubtful nature. He considered that it would be a very inadvisable procedure to remove the entire scapula if the growth were limited to the inferior angle of the scapula. An American author had collected forty or fifty cases of operation on the scapula, and came to the conclusion that removal of a portion of the bone was more dangerous than removal of the entire bone; this might, however, be a mere accident of statistics.—Mr. SIDNEY JONES agreed that the retention of the scapular processes when the tumour of the scapula was of the more innocent kind was advisable.

Mr. THOMAS SMITH read a paper on a case of Ligature of the Common Iliac Artery for Inguinal Aneurysm, with slipping of the Ligature, followed by Gangrene of the Limb and Death. The patient was a discharged soldier, aged fifty-two years, who had served in India, and had had syphilis. For two years he was aware that something had been wrong in his groin, and for two or three months the right lower limb had been much swollen. He had an aneurysm reaching from below Poupart's ligament up to a point midway between the crural arch and the umbilicus; there was a strong pulsation, but no bruit; in other respects he seemed a healthy man. The artery was tied above the aneurysm on Oct. 22nd with a carbolised kangaroo tendon; the pulsation was at once arrested, but the next day the pulsation returned in full force. The artery was again exposed; the ligature was found *in situ* with no appearance of loosening, but the point of an aneurysm needle could be inserted between the vessel and the ligature; it was therefore removed, and two carbolised silk ligatures were placed on the artery, one above and one below the site of the first ligature; pulsation ceased at once. In forty-eight hours the pulsation returned, and continued until the day before death. The limb becoming gangrenous, amputation was performed, but the patient died three days afterwards, and twelve days from the date of the first operation. The post-mortem examination showed that the common iliac had been tied just above its bifurcation; it was closed by clot for half an inch above the upper ligature. The external iliac was dilated in its upper third; its lower two-thirds formed a large fusiform aneurysm, extending beneath Poupart's ligament, and involving the common femoral. The internal iliac was closed by clot for one inch below the ligature; the common femoral was filled with dark adherent clot, as also was the superficial femoral and the profunda. No veins had been injured in the operation: the external iliac vein was normal; the common femoral and its tributaries were filled with clot, the vein being compressed by the aneurysm beneath Poupart's ligament. There was no general peritonitis, but some matting of the intestines in the immediate neighbourhood of the ligature. The aneurysm was filled with a firm clot, a large part of which was laminated. The fatal issue of the case was primarily due to pressure on the main vein causing gangrene of the limb, one of the most common causes of death in aneurysms in this situation. Mr. Smith attributed the yielding of the ligature to the slippery nature of the material used; the wound being very deep, it was probable that the first loop of the knot slipped to some extent before the second knot could be tied, and though for a time it controlled the pulsation, it probably yielded to a small extent afterwards; the artery being very large, the knot was subjected to a considerable strain. He called attention to the defects in the method of applying ligatures to large arteries in their continuity by the single thread fastened by a reef knot. The object of the ligature being to constrict the vessel evenly at all points of its circumference, so that no one part of the vessel is pressed upon more than another, he maintained that the ordinary ligature did not fulfil these conditions; but that the knot dinted in the arterial coat where it lay over the vessel, and that when the ligature divided the artery it was the knot that first penetrated the canal of the vessel; he also pointed out that where secondary hæmorrhage occurred it was usually at the site of the knot. As a remedy he recommended that the

ligature should be passed twice round the vessel as a clove hitch, and the opposite ends be pulled firmly across the artery; this ligature, having no knot, compresses the artery evenly at all points of its circumference, and is very firm and tenacious. He believed it to be quite trustworthy. Notwithstanding the accidents that occurred in the case related, Mr. Smith still believed the aseptic kangaroo tendon was the best material we possessed for the ligature of large arteries in their continuity, and that there was no fear of its slipping if the manner of securing it was adopted which he advocated. But if this method was not considered secure enough, the ends of the clove hitch could be tied in a single knot after pulling the clove hitch tight; this, he believed, to be superfluous; but if it were done, the knot would not be in contact with the arterial walls and could do no harm. The views he entertained, he believed, derived additional importance from the publication of Dr. Edmunds and Mr. Ballance's paper, as they had proved that it was not necessary or desirable to injure the coats of an artery in order to secure a permanent obliteration of its canal.

Mr. BUTLIN read a paper on a case of Axillary Aneurysm, for which the subclavian artery was ligatured in the third part of its course, in which slipping of the ligature occurred shortly after the operation, and after re-ligature was followed by collapse and death. The subclavian artery was tied in the third part of its course by Mr. Butlin for an aneurysm of the axillary artery in the axilla. The artery was large at the seat of ligature and was slightly adherent to its sheath, but no difficulty was experienced in performing the operation. A slightly flattened kangaroo tendon was used. The artery was tied in two places with an interval of about two-thirds of an inch between the two ligatures, and the vessel was divided. Half an hour after the operation violent hæmorrhage occurred, and was controlled with difficulty by means of pressure. It was found that the ligature had slipped off the proximal end of the divided artery. A silk ligature was applied, but not before a large quantity of blood had been lost. The patient died the same night. The knot of the kangaroo ligature had not slipped, but the ligature had slipped over the end of the retracted artery, probably from being drawn up against the outer border of the scalenus anticus muscle. The hæmorrhage was immediately preceded by a violent fit of coughing. It was not possible to ascertain, either during the application of the second ligature or at the post-mortem examination, whether the kangaroo tendon had divided the middle and internal coats of the vessel, but the sensation communicated to the operator was that they were not divided. The case is related to show that it is not safe to employ a ligature such as kangaroo tendon in the tying of a large artery when the vessel is divided. Even if such an incident as that which has been related had not occurred, the knots tied in these ligatures are apt to slip. The case cannot be employed as an argument against either the kangaroo tendon or against the division of the artery between two ligatures; but may be used against the combination of the two methods.—Mr. CROFT inquired the condition of the artery within the grip of the ligature in Mr. Smith's case, and whether the internal and middle coats were divided. In April, 1881, he had used flat kangaroo tendon to the external iliac artery for aneurysm of that artery. He had made a second knot in this case because the material seemed slippery and elastic; it was intended that the middle and internal coats of the artery should be divided, but whether this happened or not he could not say, as the man made a perfect recovery. His bias was in favour of double ligature with division of the vessel between. He had used this method but once, and this in ligature of the common carotid artery. In ligature of an artery for a fusiform aneurysm recurrence of pulsation was not perhaps surprising, and this without supposing that the ligature had slipped.—Mr. CHARLES BALLANCE said that in the ligature of large arteries in their continuity in horses, donkeys, and sheep kangaroo tendon was perfectly efficient, and caused perfect occlusion of the vessel without risk of ulceration and without rupturing the internal coats. Kangaroo tendon loses its glistening appearance, and becomes opalescent and somewhat rough, if placed for a short time in a solution of corrosive sublimate. He had seen kangaroo tendon used to ligature the femoral artery in a case of popliteal aneurysm, and with complete success. In another case the same kind of ligature was used for hæmorrhage, the femoral also being the artery tied. The boy died, but the vessel was found to be occluded without rupture. He considered that the reef knot was a very good one, and could be employed without damage to the arterial coats. He hoped to have the opportunity, however, of trying Mr. Smith's clove hitch. In Mr. Butlin's case he would not have divided the vessel, but would have trusted simply to the kangaroo ligature.—Mr. BARWELL commented on the return of the pulsation in twenty-four hours in Mr. Smith's case, and thought this could not have been the result of slipping of the knot. In his opinion the recurrence of pulsation should be attributed to the setting up of an unusual collateral circulation. Knots of kangaroo tendon or ox-aorta ligatures do not "eat" or "cut" into the coat of the vessel like the knots of smaller ligatures. In a case of ovarian tumour, where the pedicle was tied with a thick piece of catgut in a perfect reef knot, Mr. Barwell thought there was evidence at the necropsy that the length of the ligature within the knot had increased. He could not concur in the opinion that the clove hitch would prove of service in ligature of arteries in their continuity.—Mr. SIDNEY JONES related his experience of ligature of the vertebral artery. In one case there was severe hæmorrhage, doubtless due to ulceration of the vessel. If he should have to ligature an artery so tightly stretched as the vertebral artery again, he would apply two ligatures and divide the vessel between. Reference was made to a case of deligation of the subclavian artery for axillary aneurysm; the artery lacerated whilst the aneurysm needle was being passed. Fortunately he was able to apply chromicised catgut ligatures above and below the rent in the artery, and so stopped the hæmorrhage. No further serious symptoms occurred, and the wound healed naturally.—Mr. HENRY MORRIS said that the knot could cause an injury to the wall of the vessel; in one case, in which chromicised catgut was used to the femoral artery for popliteal aneurysm, the artery ruptured; it had to be ligatured above and below and the artery divided between the ligatures. In deligation of arteries in their continuity, he advocated the use of kangaroo tendon and division of the artery between the ligatures. The degree of pressure which could be exerted by kangaroo tendon was very much less than that produced by catgut or silk. In his opinion the ligature had been applied sufficiently tightly in Mr. Smith's case. It was not an uncommon circumstance for pulsation to reappear in twenty-four hours, and it often subsided later on of its own accord.—Mr. SMITH, in reply, said he could not state certainly whether the internal coats were divided by the kangaroo ligature, but he thought not. In the practice of applying two ligatures and dividing the artery between, he was but following the method of Celsus, Galen, Ambrose Paré, and Paulus Ægineta. The tendon had a glistening appearance, though it had not been kept in carbolic oil, but in a watery solution of carbolic acid. In Mr. Ballance and Dr. Edmunds' experiments, it was found that the knot region of the outer tunic had given way; he agreed that this risk was less with kangaroo ligatures than with others. As he would be happy to show Mr. Barwell, the clove hitch could make a very firm knot.—Mr. BUTLIN said that he had no doubt of the slipping of the ligature in Mr. Smith's case; the pulsation in the aneurysm was as forcible as ever twenty-four hours after the deligation. If the return of pulsation was due to the establishment of collateral circulation, he asked how it was that the application of fresh ligatures with division between could be followed by the cessation of pulsation for a period of forty-eight hours, as was actually the case. A kangaroo tendon was liable to slip, and he ventured to think that, if silk had been used in his own case, the event would have been very different.

The following living specimens were shown:—Mr. Stephen Paget: (1) A mother with two children, all three presenting Congenital Absence of the Irides; (2) Pigmentation of Conjunctivæ. Mr. Keetley: Erasion of the Condyles of the Femur for Strumous Disease, there being no shortening of the limb, as there would have been had excision been performed.

MEDICAL SOCIETY OF LONDON.

Paralysis Agitans.—Aneurysm of Aorta.—Pouch of Penile Urethra.—Tubercular Disease of Ankle-joint.—Carcinoma of Prostate.

A CLINICAL MEETING of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. SAMUEL WEST read a case of Paralysis Agitans of ten years' duration, which began immediately after the receipt

of an injury inflicted by the pole of a waggon. The patient, a cabman, aged fifty, was seen at St. Bartholomew's Hospital ten minutes after the accident, and there was then rapid tremor of the right hand and arm. The temperature in the right axilla was a degree higher than that of the left. There was some loss of sensation in the right arm. The leg was the seat of a few tremors. An abscess formed over the sacrum, but healed in a week. The patient was under observation for some months from the time of the accident. At the end of six months the left side had become affected with tremors. The case has progressed but slowly for the last eight years. The cardinal symptoms were well marked.

Dr. THEODORE WILLIAMS exhibited a case of partially consolidated Aneurysm of the Transverse Portion of the Arch of the Aorta. The patient, a man (who was shown), aged forty-two, a waiter, with a history of rheumatic fever, had complained for one year of pain in the chest, cough, and more recently of short breath and slight dysphagia. He was admitted into the Brompton Hospital in July, 1885, and the diagnosis was aneurysm of the transverse portion of the aortic arch pointing in front, pulsation being visible in the upper three intercostal spaces on the left side. Under treatment by rest and iodide of potassium the patient greatly improved; the dysphagia ceased, and the pulsation became less visible, but irregularity of the size of the pupils was noted before he left the hospital, which he did four months later. He resumed his occupation to a limited extent, but, being attacked with fainting fits, was readmitted in October, 1886, with stridulous breathing, dysphagia, and some dyspnœa, unequal pulses and pupils, the left pupil being widely dilated. Dr. Williams found the aneurysm still tolerably solid in front; it had extended backwards, and involved the recurrent laryngeal nerve, giving rise to fixation of the left vocal cord and great stridor of breath. There was also evidence that the trachea was pressed on. The points of interest in the case were—1. The rapid consolidation of the sac in front, and the cessation of the dysphagia during the patient's residence in hospital. 2. The stability of the clot, even under the unfavourable circumstances of his occupation. 3. The rapid extension of the aneurysm posteriorly at a later date.—Dr. SYMES THOMPSON referred to treatment other than iodide of potassium: complete rest in the recumbent posture and very low diet.—Dr. A. MONEY asked what the position of the vocal cords was.—Mr. JAMES BLACK inquired for the presence of cough in this case.—The PRESIDENT referred to the works of Tufnell, who advocated measures calculated to give the body the most complete rest.—Dr. WILLIAMS, in reply, said that the left vocal cord was in the cadaveric position. The patient had a cough of laryngeal quality.

Mr. E. HURRY FENWICK showed a case of Pouch of the Penile Urethra in a patient aged fifty-seven, who had suffered from stricture for the last eighteen years. The difficulty of micturition culminated in extravasation of urine a year and a half ago. Perineal incision was performed, and a large sac with several small facetted stones and one large one were removed. Urethral fever followed, but the man ultimately recovered. The pouch was probably due to distension of the canal behind an anterior stricture. It was proposed to pare the edges of the antescrotal sac at the same time that the bladder was drained through the perineum.—Mr. J. H. MORGAN considered that Mr. Fenwick's explanation of the nature of the pouch was correct. Instead of performing any cutting operation, he would be inclined to employ steel sounds with a view to dilating the strictures, and trust to the mechanical stimulus to improve the tone of the muscular coat.—Mr. BRUCE CLARKE thought something more than sounds and catheters would be required: excision of a portion of the urethra and joining together the cut ends.

Mr. E. HURRY FENWICK also showed a case of Strumous Disease of the Tibia and Ankle-joint. Amputation was considered necessary; but on making the requisite incision it was thought that arthrectomia synovialis would prove more successful than having recourse to amputation. The lower end of the medulla of the tibia was scraped away with the curette.—Mr. KEETLEY confirmed the statement that removal of the diseased medulla was a perfectly safe procedure, and indeed to be desired, as likely to make the case more successful. It did not prevent perfect healing of the bone.—Mr. W. ADAMS spoke of the success of the case, which was mainly due to free incisions.—Mr. FENWICK, in reply, said that Mr. Keetley's suggestion to scrape out the medulla even in cases of acute osteomyelitis was a most valuable one.

Mr. E. HURRY FENWICK also brought forward a case of large Inguinal Hernia, which had developed for the most part during the last six months, apparently as the result of straining; there was found to be carcinoma of the prostate.—The PRESIDENT asked whether there were deposits of cancer elsewhere in the body. He had seen a case in which double optic neuritis led to the belief that there was an intracranial tumour.—Mr. B. JESSETT had seen two cases of carcinoma of the prostate. Was there any cystitis?—Mr. BRUCE CLARKE mentioned cases in which there were secondary deposits in many organs.—Dr. S. WEST mentioned a case of very rapid growth in a young man aged about twenty.—Mr. FENWICK had seen secondary growths in the liver.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The President's Address.

A MEETING of the above Society was held on Friday, Oct. 8th, Dr. F. H. Alderson, President, in the chair.

Dr. Alderson selected for the subject of his inaugural address "The Wants of the General Practitioners of the day." He considered as perhaps the greatest and most general want was that of a larger income. Amongst the causes of diminished medical incomes, Dr. Alderson mentioned the crowded state of the profession, giving some statistics to verify what he considered might be accepted as an axiom, but asked, "Has it not become a question for our direct medical representatives *in futuro* whether some steps should not be taken by our somewhat torpid Medical Council to reduce this excess and to bring our too easily made doctors more within the requirements of the public and profession? for excess in numbers means poverty in quality." Dr. Alderson suggested that the arts examination of the medical student should not be passed before the age of eighteen or nineteen; that the first class second division of the College of Preceptors should be the lowest standard for acceptance for registration by the Medical Council; that some knowledge of Greek should be required of every aspirant to medicine; and that one or two years should be spent either as an assistant to a medical man, or as house-surgeon, house-physician, or resident obstetric assistant at a hospital, after the usual hospital curriculum was completed, before commencing independent practice. Other important causes of reduced incomes were the improved health of our cities and towns, and for this reason he advocated the principle of "health assurance"—i.e., the practice of paying medical men annually, ill or well, a certain fixed payment, which, if universal, need not be large. Amongst the propositions suggested for the expansion of medical incomes was that of the appointment of pathologists in every district, and likewise of school visitors and of School Board examiners, from the ranks of medicine. Death certificates ought to be paid for; they would then become more valuable, because perhaps they would then be more accurately and less hastily written. Dr. Alderson thought all hospital appointments should be paid for; more time and thought could then be given to hospital patients. A great grievance under which general practitioners laboured was the rule by which many hospitals exclude everyone in general practice from being eligible for either the post of physician or surgeon. By such a regulation he considered surgical skill was limited and surgical knowledge narrowed. By Dr. Alderson's suggestion of every man in general practice who desired it becoming a public vaccinator he believed the compulsory nature of the Act would appear to be considerably lessened, the supply of lymph would be much greater, vaccination would be more efficiently performed, and the Act become much more popular. In respect to the ethics of consultations, the speaker thought consultants should more frequently, and indeed perhaps always, follow the practice of certain leading physicians, who invariably send their prescriptions, accompanied by a courteous letter to him, even when his patient had applied to them *sponte sua*, and even without his knowledge. Home, fever, and private hospitals and dispensaries were regarded by the President as antagonistic to the interests of the general practitioner. The recent passing of the Act Amendment Bill was

alluded to. Dr. Alderson considered there was much that was wanting, but he thought by a wise selection of our direct medical representatives the Act might become both powerful and effective. The Lunacy Act Amendment Bill was still waiting completion, and medical men hesitated to sign certificates, yet he believed that the time was not far off when (if the profession be not relieved of this duty) every medical man who in good faith signs a lunacy certificate would be secured from vexatious actions on the part of the assumed or recovered lunatic or his friends. He would institute mental sanatoria for cases of temporary insanity where no patient could remain longer than one calendar month, which he believed would in many cases be sufficient for the recovery of the patient, and by this great distinction from asylums would do much to lessen or obliterate the stigma which is now so unfortunately attached to even a temporary abeyance of intellectual function of many a promising and incompleted life. The address concluded with an urgent appeal to every member of the Society to assist in the discussion of subjects brought forward at its meetings.

On the proposition of Dr. THUDICHUM, seconded by Mr. LAWRANCE, a hearty vote of thanks was accorded Dr. Alderson for his able and comprehensive address. Upwards of fifty members were present.

OPHTHALMOLOGICAL SOCIETY.

Orbital Tumour. — Ophthalmoplegia Interna. — Retinitis Pigmentosa. — Optic Nerves in Head Injury. — Ophthalmoplegia dependent on Thrombosis of Cavernous Sinuses. — Hypertrophy of Lacrymal Glands. Penetrating Wounds treated by Suture. — Complete Ophthalmoplegia with Ptosis and Blindness (? hysteria).

THE first ordinary meeting of this Society was held on the 21st inst., Dr. George Johnson, Vice-President, in the chair.

Dr. JOHNSON made some remarks on the chronic latency of Renal Disease, which was sometimes first diagnosed by the ophthalmic surgeon discovering albuminuric retinitis, the foundation of kidney disease having been laid in scarlet fever or diphtheria many years previously. The urine should be examined in all cases of illness.

Messrs. CRITCHETT and H. E. JULER showed a living specimen of Proptosis of the Left Eyeball, associated with swelling in the zygomatic region. The disease began as a chemosis of the outer canthus; protrusion of the eyeball followed and the zygomatic region began to bulge. These swellings increased, including the chemosis; the tissues at the outer canthus had a deep blue aspect. At first, and for some time after, there was no diplopia. The proptosis, which began in August, 1885, had increased for twelve months. The movements of the eyeball were greatly limited. Diplopia occurred on looking to the left. The cause of the disease was unknown. Iodide of potassium in ten-grain doses three times a day was the only remedy used, but the tumour only began to subside in August, 1886. The patient was a ballet-dancer. In reply to Mr. Nettleship, it was said that the iodide was begun early; and in reply to Mr. Power, that there was no pulsation.—Mr. CROSS mentioned a somewhat similar case in a man in which the growth gradually subsided, but not apparently as the result of the administration of iodide of potassium.

Mr. ADAMS FROST showed a case of Ophthalmoplegia Interna of the Right Eye. Near vision of the eye had been defective for three or four months. The right pupil measured 3·5 mm. and was always immobile. There was complete loss of knee-jerks, but no other signs of locomotor ataxy or other nervous disease. He had not had syphilis.—Dr. SANSOM asked for lightning pains; Dr. ORMEROD for a history of diphtheria; Dr. BEEVOR whether the optic nerve was atrophied. A negative reply was given to these questions.

Mr. ADAMS FROST exhibited a living specimen of Retinitis Pigmentosa, with deposit of pigment on the anterior surface of the lens, in a man aged thirty-five, who had had "night blindness" for years. He had had iritis in 1879.

Mr. STANFORD MORTON showed a modification of his Ophthalmoscope, which allowed of rapid changing of the mirror without risk of accident.

Messrs. EDMUNDS and LAWFORD read a communication on Optic Neuritis in Head [illegible] was based on the examination (ophthalmoscopic or microscopic) of the optic nerves in twenty-four cases. The microscopic evidence of neuritis is a considerable increase of staining corpuscles in the sheath-space and in the nerve. The cases were divided into three groups. 1. Those fatal directly from the severity of the injuries. 2. Those fatal indirectly from complications. 3. Those in which recovery took place. The neuritis was thought to be due to an extension of inflammation from the seat of injury to the optic nerves, which extension might be conceived to take place either along brain tissue (cerebritis) or along the meninges (meningitis). The authors contended that the latter path was that along which the inflammation spread, because an analysis of the cases proved that optic neuritis occurred far more frequently in those cases in which the base of the brain or skull was involved than in those in which the lesions were confined to the convexity. This fact was especially evident in the cases of Group 2 (four in number). Two of these were cases of punctured wound of the convexity of the brain followed by cerebral abscess necessitating trephining; hernia cerebri occurred, and finally death. In neither was there optic neuritis. The other two were cases of severe compound fractures of skull, with injury to the base by contrecoup, and post-mortem lesions at the base were found. In both of these there was optic neuritis. The microscopical appearances of inflamed optic nerves were shown by diagrams.—Dr. BRAILEY inquired what explanation Dr. Edmunds gave of the different histological appearances in different cases of optic neuritis; in some the sheath was more affected, in others the trabeculæ of the optic nerve itself.—Mr. A. QUARRY SILCOCK asked whether there was any meningitis in the cases without optic neuritis due to injury of the convexity of the brain.—Dr. EDMUNDS, in reply, said there was meningitis about the convexity, but not at the base. The different histological appearances were probably to be attributed to the different stage of the disease in different cases.

Dr. SIDNEY COUPLAND read a paper on a case of Ophthalmoplegia dependent upon Thrombosis of the Cavernous Sinuses. It occurred in an unmarried woman, forty-three years of age, who was admitted into the Middlesex Hospital under his care on March 10th, 1886, suffering from cerebral symptoms, including bilateral ophthalmoplegia. Her previous health had always been good, and, beyond the fact that her father and one of her brothers were said to have died of consumption, there was an absence of any inherited taint in her history. There was no evidence of syphilis. It was ascertained that in the months of January and February she had attended Moorfields Hospital, under the care of Mr. Hulke. From notes kindly furnished by Mr. W. Gay, her condition during this period may be summed up as "proptosis and more or less complete ophthalmoplegia externa of the left eye, following great supra-orbital pain, succeeded by proptosis of the right eye, with ophthalmoplegia externa and (?) interna, but with no distinct ophthalmoscopic changes." The symptoms had commenced with headache and deafness of the left ear four months before any ocular trouble; iridiplegia and strabismus, and then left ptosis, supervened. When admitted into the Middlesex Hospital she was in a drowsy condition, but pointed to the right side of the forehead when questioned as to pain. The face was dusky; but there was no enlargement of veins around the orbits or elsewhere, and no œdema of lids; marked proptosis of each eyeball; complete ptosis of right lid, partial of left. Right eye absolutely immobile in any direction, and the left only retained a slight power of movement inwards. Both pupils were large, the right more dilated than the left; total reflex iridiplegia. No optic neuritis, or other notable ophthalmoscopic change; veins not dilated; ocular conjunctiva, especially of left eye, injected; on each side it was quite insensitive. Cutaneous sensibility of left side of face impaired, as compared with right, but not wholly abolished. No facial paralysis. Deafness, but degree could not be ascertained. No otorrhœa; some dysphagia. Tongue protruded straight; arms semiflexed; slight rigidity. Legs flaccid, but movements controlled by patient. No plantar reflex on right side, and but slight on left. Abdominal and epigastric reflexes absent on both sides. Knee-jerks absent on both sides; no ankle-clonus. Cutaneous sensibility impaired over lower limbs and trunk; loss of voluntary control over bladder. Next day, the patient lay with her head turned to the left, and cried out with pain if it were moved. This symptom remained till death, which occurred on March 12th, in coma. Towards the close, the left conjunctiva became chemosed.

t the post-mortem examination, there was found basic ieningitis (both arachnitis and leptomeningitis) of recent ate; no tubercle. The pituitary body was enlarged. The avernous sinuses were plugged with old caseo-purulent and olourless thrombi; and so were the circular and transverse inuses. The petrosal sinuses were empty. No disease of ranial bones or of internal ear could be detected. The erebral ventricles were distended with fluid. No lesions i brain; broncho-pneumonia of recent date in left lower obe; slightly granular kidneys. Thus no cause of the hrombosis was discovered, and the clinical course, as well s the character of the exudation, proved that the meningitis ras far more recent in origin than, and probably secondary o, the thrombosis. The ophthalmoplegia, at first unilateral nd then bilateral, is explained by the complete obliteraion of both sinuses, the thrombosis starting in the left inus. The absence of "choked disc" accords with general xperience, being attributable to the free inosculation of the acial and orbital veins; and to the same anatomical conitions may be ascribed the absence of œdema of the yelids. Nor was the degree of proptosis much, if at all, iore than might be ascribed to the ophthalmoplegia. The bolition of many of the spinal reflexes was not explained; or was the symptom of deafness, which occurred early in he case. The paper concluded with a review of the auses and symptoms of thrombosis of the cavernous sinuses, vith especial reference to the symptom of ophthalmoplegia. n reply to Mr. Nettleship, Dr. Coupland said there was ne other case on record pretty much like his own.—Mr. ANG spoke of a case of thrombosis of the cavernous sinus n an elderly man; there was marked proptosis; the patient ad muttering delirium, and died comatose. The cavernous inus on the right side was thrombosed; the ophthalmic ein was not plugged; there was no disease of the bones.

Mr. HENRY POWER exhibited a boy, aged fourteen, in whom both lacrymal glands were enlarged. Enlargement f this gland was a rare condition, especially when symnetrical. The inunction of mercurial ointment and the pplication of tincture of iodine to the skin effected no eduction in the size of the glands. Tears began to flow rom the left eye, and much discomfort was experienced, and o about two weeks ago the gland on the left side was emoved through the skin, not the conjunctiva or external anthus, as some had recommended. The operation was ompletely successful; no trouble was experienced in regard o moisture of the cornea and conjunctiva. No cause was nown. The lacrymal gland was probably only of service or emotional purposes.—Mr. MCHARDY mentioned the case of a solicitor of advanced age, in whom swelling of the land occurred as the result of sudden emotion; it subsided lowly without special treatment. He had observed collecions of tears, in cases of removal of the gland for injury, e to portions of gland left behind.

Mr. CROSS of Bristol showed two cases of Penetrating ound of the Eyeball, with escape of vitreous, resulting, fter suture of the sclerotic, in recovery with useful vision. The success in these cases seemed to prove that ophthalmic urgeons ought to be conservative in their treatment of arge wounds of the eyeball, especially if the ciliary region e not implicated.—Dr. W. A. BRAILEY mentioned a case of evere penetrating wound of the eyeball with protrusion of itreous, in which the conjunctiva only was sutured over he gaping wound. To his surprise and pleasure, the wound ealed with fair vision, and the tension was nearly normal, hough the edges of the rent in the sclerotic had not united. —Dr. P. H. MULES mentioned two cases of foreign body in he eyeball in which he incised the sclerotic, and extracted he steel with the aid of a magnet. He thought early peration was one of the chief elements on which success was dependent.

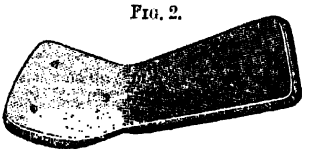
Dr. W. A. BRAILEY read a case of rapidly occurring Blindness and complete Ophthalmoplegia on one side. The patient was a single woman, aged fifty, who complained of pain round the left orbit and numbness of the left side of he head three months ago. One month later she came o Guy's Hospital stating that she had also pain in the left eyeball, which was always much more severe about 4 A.M. Distant vision, after the correction of some hypermetropic astigmatism, was perfect. The right eye was totally blind, as the result of a blow with the cork of a soda-water bottle some twenty years ago. The movements, and those of the lids, were, and have since remained, perfect, except that the internal rectus seems weak; its pupil is occluded and the iris bulged. Tension normal. No other morbid condition can be found. Patient's manner is very quiet and rather constrained. Again, three weeks later (five weeks ago), her friends noticed that the left upper eyelid drooped, and she complained of the sight being gradually worse till two and a half weeks ago, when it deteriorated very rapidly. Three days later (Oct. 8th) she was led into the out-patient room totally blind. The right eye and lid moved as before, but the left lid drooped. The eye was immovable, and the pupil was three parts dilated and fixed. The conjunctiva and skin appeared even more sensitive than normal. The fundus was normal. She was admitted as an in-patient and blistered that evening. The next day (Oct. 9th) the outward movement of the eye and that of the pupil was still absent, but the other movement had come back. There was still no perception of light. She was treated with iodide of potassium and perchloride of mercury and the vision slowly returned, but there was still considerable defect. She can count fingers, but does not seem to see a light, or at least replies in uncertain fashion. There was no definite evidence of syphilis, but, though single, she had had two children. Dr. Brailey had, like others, seen many cases of blindness of one eye, and many cases of ptosis. He had observed also two cases of one inferior rectus which from the appearances and after-history appeared to be hysterical, but never a case of complete ophthalmoplegia externa or interna. Simulation appeared to him to be out of the question, though many points in her answers to the test of vision were unsatisfactory. The case was, however, at present incomplete.—Dr. SHARKEY referred to a curious case reported by Dr. Bristowe; there was ophthalmoplegia and profuse hæmorrhage from the ears, and the necropsy failed to reveal any sign of disease in any part of the nervous system.—Mr. ADAMS FROST inquired as to the precise state of the field of vision.—Dr. BRAILEY, in reply, said that it was impossible to ascertain the exact state of the field of vision owing to ambiguity in the replies of the patient.

READING PATHOLOGICAL SOCIETY.

AT a late meeting of this Society Mr. BARFORD, of Wokingham, read a paper on Infant Mortality in the Borough of Reading. The inhabitants of the borough of Reading, he said, may be fairly congratulated on their public spirit, and the right appreciation of their responsibilities, as displayed in an improved system of sewerage, at a cost of £320,000 sterling, and therefrom an appreciable lessened death-rate. The mortality stood for the twenty years between 1850 and 1870 at 22 per 1000, having previously been as high as 24 per 1000; while during the ten years between 1870 and 1880 it has been reduced to an average of 19 per 1000, and since then in one year it reached a death-rate as low as 14 per 1000. Such a result should be a sufficient satisfaction to the inhabitants of the borough for their large expenditure and consequent heavy rating. It represents the saving each year of more than 100 human lives, for, as the mean population of Reading during the period under consideration averaged 38,000, a reduction of the death-rate by 3 in the 1000 gives the result mentioned. A comparison of the death-rate of Reading with two other registration districts in the county, Wallingford and Abingdon, is favourable to Reading, though both these towns are far less populous. This Society may fairly look to any of its members who practise in or around Wallingford and Abingdon for information, which they above all others must possess, which may afford a clue to the cause of this higher death-rate in Wallingford and Abingdon. Yet, with a higher general mortality, both these towns have a lesser infant mortality than Reading. But while Reading compares favourably in the general death-rate with two other registration districts in the county, it compares unfavourably with nine others. The general death-rate in Reading is higher than in the districts of Newbury, Hungerford, Farringdon, Cookham, Easthampstead, Bradfield, Wantage, Wokingham, and Windsor. The infant mortality is very much in excess of these. Taking the two registration districts adjacent to Reading—that is, Wokingham and Bradfield—the annual mortality in these is in one instance 15 per 1000, and in the other 16 per 1000, while Reading for the same period stands at 19 per 1000. As originally the death-rate in Reading was 24 per 1000, and has now been reduced to 19, the question may fairly be asked of membe[illegible] Can any further reduc-

tion be effected to make the death-rate of Reading approach still nearer the lower death-rates of the adjacent districts of Bradfield and Wokingham? Cannot this be aided by lessening the large infant mortality in Reading? I anticipate that one answer to the questions will be, that Reading is a thickly-populated town, while the other districts are more or less rural. This leads me to a comparison between Reading and Bedford, which resembles it more than any other town I am acquainted with. The population of the registration district of Bedford is 42,000, that of Reading district 38,000. Thus, a comparison should be a little in favour of Reading. Both towns have points of resemblance, though they differ in size; they are the centres of considerable, but not unhealthy, manufacturing industries; there are large schools attracting pupils from all parts; both have streams running through them; both are thriving, well-to-do towns, in which poverty should be reduced to a minimum; in each there is a county hospital. Why, then, is it that in Reading from thirty-eight to forty human lives are sacrificed every year over and above what takes place in Bedford? Is it not a fitting labour for this Society to sift out the causes of this higher mortality? Already, I think, one of our junior members has given a clue to one cause, in his reference to the high infant mortality in Reading—fed, as he assured us some infants are, on pap and gin. If the infant mortality in Reading be traced, it will be found to be higher than any other district of the county. Out of 1000 infants born in Reading, no less than 139 die during the first year of their existence, while in an adjacent district only 99 die out of every 1000. Here, then, is one source of a higher death-rate in Reading and a sad reflection on maternal care. The marriage-rate in Reading is a high one, for it amounts to 19 per 1000 persons living, as compared with 11, 12, and 13 in other districts of the county. This is held to be a fair indication that the people are well occupied and well-to-do, and therefore able to afford nurture for their offspring. The birth-rate in Reading is low compared with the marriage-rate. Some explanation may be afforded by this Society of the low birth-rate compared with the high marriage-rate. Why should fewer children be born in Reading, as compared with the number of marriages, than elsewhere in the county? Why should a larger proportion of children born die in the first year of their existence? What are the barriers to conception? are they natural or artificial? This Society can answer those questions. Here is subject matter for thought, for the moralist and philanthropist, for the clergy, for right-minded matrons, as well as for doctors. Are the mothers of infants drawn off from their domestic duties to the factories? If so, could not the crêche system be established in Reading? There is a benevolent Mayor of the town, deeply interested in all movements for the public good. The chiefs of the manufactories are benevolent also. Do their works attract mothers through a love of gain, or through necessity, to the neglect and death of their infants? If so, a committee formed of the borough member, the Mayor, and some of the larger employers of female labour, of a few of the clergy and medical men of the town, would be sufficient to deal with this subject, and remove the slur of an excessive infant mortality from the town of Reading. The lives of at least forty infants might be saved every year. Each life has a distinct commercial value to the State. Thus upon the lower grounds of finance these lives are worth preserving. Each premature death is a reflection on us as a profession; it is therefore our duty to contend with the cause. Is sufficient care taken in giving certificates of the cause of death? Are investigations by inquest evaded? The greatest safeguard against an excessive infant mortality is a full and impartial inquiry into the cause of uncertified death. It is clearly the duty of all the members of this Society practising in Reading to exercise the greatest vigilance in all matters affecting infant mortality. Cannot these facts be represented to the coroner? There are forty lives to be saved each year within the borough among children under one year old. Here, then, is work enough for a time, apart from what I propose on a subsequent occasion to consider under the head of "Special Disease Tendencies." The borough is watched over by a medical officer of health in whom we all have confidence. Cannot this Society aid him in his efforts to lessen the death-rate by some action outside his legitimate sphere? To this end it may be asked, Why should the connubial disposition be above the average? Why should procreation be below the average? Why should [illegible] adequate to the average preservation of offspring? These questions the Pathological Society of Reading can answer. It may be the means of saving many a life now sacrificed.

New Inventions.



A NEW SPLINT FOR COLLES' FRACTURE.

As a general rule, the more methods of treatment advocated in any surgical injury, the more proof it is that none meet all the requirements of the case. So it is with Colles' fracture. We have the pistol splint, Carr's splint, Gordon's splint, and many other varieties, all recommended more or less by different surgeons, but none seem to give universal satisfaction. This it is that has led me to recommend yet another form of splint, which I have found extremely efficient. The requirements of a good splint are simplicity, lightness, ease of application, and maintenance of the bones in position by counteracting the distorting forces. I think the splint I recommend combines these qualities. In Colles' fracture we have a triple displacement. The lower fragment, the hand with it, is displaced upwards and inwards; the lower end of the upper fragment is thrown forward on to the front of the wrist, chiefly by the action of the pronators. These displacements must all be remedied; consequently the pistol splint was made with a curve to the ulnar side, and Gordon's splint has an antero-posterior curve, each tending to overcome individual displacements. The accompanying woodcuts will show that the splint recommended has a double curve, antero-posteriorly

FIG. 1.

FIG. 2.

and to the ulnar side, and the hollow for the ball of the thumb allows the hand to be maintained in complete pronation without injurious pressure on that part. It is easier to pronate the hand to meet the shaft of the radius than to supinate the shaft to meet the lower fragment.

Fig. 1 represents a front view of the splint, and shows the antero-posterior curve; Fig. 2 represents a back view, and shows the lateral curve. In applying the splint, the displacement is reduced and the hand laid on the splint, so that the ball of the thumb fits into the hollow, and the fingers grasp the end so that it lies across the line of the carpo-phalangeal joints; a small pad of lint may be placed on the dorsum of the lower fragment of the radius, and a bandage applied over the whole. After the fourth or fifth day the fingers may be loosened, and a bandage applied from the back of the hand upwards, so that the fingers may be regularly moved without disturbing the fracture. The lower surface of the splint consists of a thin sheet of metal, the upper surface of a layer of cork, which can be cut to the required extent for the ball of the thumb. It is easily and cheaply made, Messrs. Aitken and Co., of York, making them at the small cost of 15*s.* 6*d.* per set of six pairs.

House-Surgeon, Newcastle-on-Tyne Infirmary

THE LANCET.

LONDON: SATURDAY, OCTOBER 30, 1886.

INTER-RELATIONS OF MEDICINE AND SANITATION.

In a sense medicine is something different from sanitation, because the cure of disease, popularly at least, appears to be a matter by no means identical with its prevention. This is, however, only so far as appearances are concerned. In truth and fact, the cure of disease is a part of sanitation, and as further progress is made in the science and art of healing it will be demonstrated that the only real cure for disease is the re-establishment of health. Disease is not an entity. It is not a thing apart from the organic life and function of the body affected, but a state or condition, either structural or functional, which is incompatible with the orderly processes of life. And it is in the change of this state or condition, so as to place matters on a footing of health, that "cure" must consist or amelioration be accomplished. In short, the physician is a minister of health to the sick, by abrogating what is unhealthy and re-establishing health. The old notion of fighting "disease" as an antagonistic force has been superseded, in the progress of science, by one of repairing or readjusting that which is injured or out of order. This change of method in connexion with the treatment of disease has necessitated a reconstruction of the whole system of medicine, and it is on this that the scientific revolution which has been proceeding during the last fifty years has been based. The change is even greater than many of those who have been the subjects of its influence adequately realise. We have, so to say, been carried from north to south, the direction of our progress being almost completely reversed, but so gradually that not only has there been no revulsion of feeling, but we have scarcely been conscious of the change. One of the most remarkable and yet unappreciated effects of the change of front accomplished has been to convert the army arrayed against disease into a pacific body bent mainly on the prevention of that very war in which our predecessors gloried. To the interests of the population at large the consequent gain has been enormous, but it cannot be disguised that upon the profession there has been entailed a loss of both prestige and recompense, which is only just beginning to be realised. The policy of the day—in Physic at least, for Surgery in great part stands on another footing—is one of self-effacement. If only that policy could be thoroughly carried out, the issue would be to abolish disease, and thereby, as it would seem, to put an end to the need of doctors. In proportion as it is possible to give effect to the policy adopted will disease be minimised.

In an address delivered on the 5th inst., before the American Health Association, by Dr. NATHAN ALLEN, one, and the most prominent, view of this question is discussed as follows:—

"It is just to state here that the claims of the sick poor have been most liberally responded to by physicians, and that no other profession or class of men do so much for the poor as the medical profession. But this work of charity has its equivalents—it secures to the physician a stronger hold on the affection and confidence of the people, and, in different ways, tends to increase his business. But to engage actively in means to prevent disease, not simply in one instance, but in case of great numbers, this is very different—it cuts off directly the support of the physician. Such action is based upon a love of humanity—of philanthropy—a higher range of motive than that of giving services to the sick poor. It appeals to the very highest class of motives—not simply to save expense and relieve suffering, or improve health and prolong life, but to elevate mankind, and increase, physically, mentally, and morally, the sum of human happiness. Such are the legitimate fruits of sanitary science. Considering the powerful pecuniary interests of the profession, and the disinterested motives requisite to engage in sanitation work, it is rather surprising that so many members of the profession have from time to time engaged heartily in advancing sanitary science. The main object must have been the promotion of health, the diffusion of useful knowledge, and the enlightenment of mankind generally in respect to the laws of health and life. In some few instances, it might have been prompted by pecuniary considerations—the individual holding some official position, or seeking one. But these are exceptional cases."

In the main, there can be no "ulterior motive"—as the cynical phrase goes—in this policy of general enlightenment and the prevention of disease to which the medical profession, not only in this but in other countries, has committed itself. It is as though the lawyers should suddenly devote themselves to the propagation of useful knowledge, having for its object the putting an end to all difficulties in the transaction of business, and the general conduct of commercial and social and personal affairs, so as to render every man in a really practical sense his own lawyer. We are making the public the guardians of their own health, and showing them how to do without that advice the giving of which constitutes the bulk of our professional business. It is well to look this fact in the face. Why do we act thus suicidally? Is it that we are either wholly oblivious to our own interests, or so shortsighted as not to know what we are are doing? Neither of these propositions is the true one. It is in virtue of that complete change of front in the treatment of disease, not less than in its prevention, which has come over our scientific policy during the last half-century, and which each year is being strengthened, that this change in our relations with the public has been effected. We cannot either lay claim to exceptional virtue or confess to more than the ordinary amount of obtusity. There has never been any inscrutable mystery about the treatment of disease. Charlatans have tried to cloke their ignorance with pretence, but the true professors of the healing art have in all ages and countries rather erred on the side of loquacity as to their views and principles of procedure, than hidden or disguised them. Whilst it was believed that disease was something like an entity to combat and struggle against, using drugs and the appliances of art as weapons, this theory found ample expression in the works and utterances of the doctors. Now that it is felt that the re-establishment of health is the true method of procedure, that view is expounded with equal liberality; and as it goes without saying that if what will prevent or correct departures from the line of health-preservation must be better than cure, so by a perfectly natu[illegible] exceptional philan-

thropy or shortsightedness on the part of the medical profession, physic comes to be a matter of sanitation. This we take to be the true explanation of "The Relation between Sanitary Science and the Medical Profession," which formed the subject of Dr. NATHAN ALLEN'S address of the Health Association.

The point to state plainly and to enforce with emphasis is the fact that the principles of the most advanced method of medical practice are the rectification of errors of function and the obviation of faults and errors in structure in such way as to restore that order of life on which health depends. The nomenclature of disease is regarded more as a means of intercommunication between medical men than as of value in itself. We treat the *patient* rather than the disease, and, in so far as the disease occupies us, it is in its character as a departure from the formula of physiological order rather than as a thing of itself. This is what the profession should bear in mind, and the public ought to understand.

WE drew attention in a recent issue to the *rationale* of the high altitude treatment of phthisis. We were able to point out that this method of treatment, however novel and opposed to medical tradition, is theoretically defensible on the lines of ascertained knowledge, and that its efficacy in phthisis is deducible from admitted principles of climatology. We propose now to consider briefly the varieties of phthisis to which it is applicable, and, as in our former article, we shall proceed deductively rather than inductively.

The three chief characteristics of the climate of high altitudes were shown to be purity of the air, aerial rarefaction, and cold. Purity of the air being equally essential in all types and stages of phthisis, we cannot derive from this factor any help in the selection of cases for the mountain treatment, but the due consideration of the remaining two is capable of affording valuable instruction and guidance. The atmospheric rarefaction throws a greatly increased strain upon the circulatory apparatus; hence, we conclude that valvular disease of the heart or feeble circulatory power is a strong contra-indication against the adoption of the high altitude treatment. For a similar reason this method of treatment is inapplicable to persons of advanced age, in whom the arteries are likely to have undergone more or less senile degeneration. The rarefaction of the air increases the number and depth of the respirations, and promotes the elimination of carbonic acid from the pulmonary epithelium. Hence it presses hardly upon those who do not possess a sufficient remnant of functionally competent lung to react to the increased strain thus thrown on the breathing apparatus. Cases, therefore, in which there is extensive destruction of lung tissue are unlikely to profit by the high altitude treatment.

It was long thought that hæmoptysis was a contra-indication to having recourse to the mountains—an idea founded no doubt on a mistaken analogy drawn from the experience of mountaineers, who not uncommonly suffer from epistaxis or melæna during their expeditions. Now, no fact in connexion with this question is better established than that hæmorrhage is rare at high altitudes, even in patients who suffered repeatedly from it while resident on the plains. A little reflection will show that there is no real discrepancy between [illegible] urgent phenomena. The conditions of blood-pressure at the orifices of the body and in the lungs are not only not identical, but are actually reversed. Anæmia or congestion at the surface of the body implies an opposite condition of the viscera, and among them of the lungs; hence the fact that epistaxis occurs at high elevations, so far from warranting a dread of hæmoptysis, is rather a ground of security against its occurrence.

The prevalence of cold at high altitudes leads us to conclude that cases of phthisis complicated by renal or rheumatic affections are unlikely to benefit by this line of treatment. We infer, also, that sufficient constitutional vigour to resist the depressing influence of low temperatures is a *sine quâ non* of a successful result; but it must be borne in mind that, while the shade temperature at Davos may be many degrees below, the thermometer in the sun often registers as much as 100° of heat. This sharp contrast between the sun and shade temperatures is one of the apparent drawbacks to the climate at high altitudes, but the risk of chill is to a very large extent obviated by the extreme dryness of the atmosphere.

The combination of cold, dryness, and rarefaction constitutes a climate of a highly stimulating type; hence we should expect to find that phthisical patients of the neurotic temperament would be unduly excited by it, while the torpid and phlegmatic might be expected to profit from such stimulation. Organic nervous disease, marked functional nervous excitement, especially hysteria, and persistent sleeplessness, are on similar grounds likely to prove strong contra-indications to the adoption of the high altitude treatment. The nature of the response of the organism to disease may afford us valuable guidance in this connexion. Where high temperature, rapid emaciation, and much prostration indicate profound constitutional disturbance, we may conclude that the mountain treatment is inapplicable, the probability being that it would tend to aggravate the inflammatory processes and precipitate the fatal issue, which is but too certain to ensue in such cases, whatever line of practice be adopted. On the other hand, cases of chronic and stationary phthisis, with slight constitutional disturbance, are likely to react favourably to the stimulating properties of the climate of high altitudes.

The foregoing conclusions, which are fairly deducible from a due consideration of the conditions of the case, are verified by practical experience. The cases that do best at high altitudes are those of simple phthisis in patients who are free from cardiac, renal, or rheumatic complications, and who exhibit a torpid reaction to the disease.

Many cases of respiratory disease, other than phthisis, benefit strikingly by the high altitude treatment, notably cases of delayed convalescence from pneumonia and fibroid pleurisy. Here the explanation is not far to seek. Such cases need before all things a stimulation of the vital powers to enable the affected organs to rid themselves of morbid deposits and resume their normal functional activity, and this stimulation is precisely the most essential physiological effect of the mountain climate. The only precaution necessary in such cases is to guard against a premature adoption of the high altitude treatment. In early convalescence, where there is still some lingering pyrexia with feeble digestive power, such a line of practice would run the

risk of promoting a recrudescence of disease, but at a somewhat later stage its value is alike theoretically evident and demonstrated by experience.

THE Farnham registration district has for years suffered from an exceptional prevalence of diphtheria, the death-rate from this disease being three or four times as great as that of the whole of England. Last year a thorough investigation was made for the Local Government Board into its sanitary circumstances, and the report of Mr. R. D. R. SWEETING, the inspector entrusted with this duty, is before us. It is unnecessary for our purpose to do more than to consider a portion of the area which is included in the sub-registration district of Frimley, for our attention has been directed solely to Frimley proper and to Camberley and York Town adjacent. When Mr. SWEETING visited this neighbourhood in 1885, he found no other provision for water-supply existing than wells scattered throughout it, and which varied in depth from ten to thirty-five feet; in Camberley and York Town a main drainage scheme had been recently completed, but in Frimley proper the excrement was mostly deposited in privy cesspits. Refuse was generally thrown on the ground or made into heaps, a few of the better houses alone being provided with ashpits. The pollution of the soil must have been matter of common occurrence, and the pollution of surface wells must have taken place as the result. Fatal throat affections have been prevalent alike in Frimley and in Camberley and York Town, registered mostly as croup and laryngitis. There can be but little doubt that some of these were of diphtheritic nature; indeed, in one family a death certified as due to cynanche tonsillaris was followed shortly afterwards by another death in the same family, the disease being then described as diphtheria. For the prevention of the extension of this malady, the authorities appear to have depended entirely upon the occasional closing of schools, and upon disinfection. No system of notification of infectious disease existed, and no hospital provision, either locally or elsewhere, was available for the isolation of such cases.

It might have been anticipated that the presentation of a report stating in detail the sanitary wants of the district would have roused the sanitary authority to take active steps to improve the conditions under which the inhabitants live, and to give facilities for the isolation of any persons suffering from disease which exposed the neighbourhood to danger. To state that they have neglected this obvious duty is no exaggeration. The only water-supply which is procurable by some five thousand people is that from surface wells, which at the best of times are liable to pollution; no hospital has been erected, and Frimley is still without any system of drainage. Even the arrangements for flushing the drainage of Camberley and York Town are defective, for no sufficient water-supply exists for this purpose. No wonder the inspector reported that "the rural sanitary authority does not appear to be alive to its important health functions, no steps of any moment having been taken to improve the hygienic condition of the large district committed to its charge, and no means adopted to check the serious epidemic of diphtheria which has ravaged it."

Recently the district has been again inspected by Mr. GEORGE TURNER on behalf of the Local Government Board, but while his report is in preparation Camberley and York Town are again smitten with diphtheria. In the course of about a fortnight persons to the number of seventy-six have been stricken with this disease, and thirteen deaths have taken place. This time the disease is not limited to the poor, but has invaded the houses of the more wealthy inhabitants of the district. There is great probability that the origin of the outbreak is in some way connected with a milk-supply. The acting medical officer of health has clearly indicated this; and it certainly appears to be the fact that most, if not all, of the cases had partaken of this particular supply, whilst others obtaining their milk from other sources, although living in the same neighbourhood, escaped. Assuming, however, that milk was the vehicle, the source and nature of the infection of that fluid has not yet been traced. The action of the sanitary authority is characteristic. They have limited their proceedings to considering certificates, on the one hand, that the water supplied to the farm and the milk it produced were of proper chemical constitution, and, on the other, that the health of the cows was satisfactory, and have apparently shut their eyes to the large physiological experiment which has been conducted in their midst. A notice has been issued recommending the boiling of milk, but this is all that has been done to prevent the consumption of an article of food which, it is likely enough, may still retain the power of inflicting loss of life. In the meantime the sanitary authority ask the help of the Local Government Board, as if it were the business of this Board to supply the wants created by local incapacity. That such help will be given we sincerely hope, for other reasons than those which relate to the rendering of assistance to an indolent local authority make it desirable that milk outbreaks should be investigated. The time for instituting such inquiry is perhaps opportune, for the inspector's visit to the district will bring to the knowledge of the Local Government Board the filthy condition of the Blackwater river, which runs through the district and forms the boundary of the farm from which the infected milk is said to have come. Men are now engaged in digging out the black sewage which comes from the Aldershot camp, and which checked the flow of water by its accumulation. It will be interesting to see whether the sanitary authority can be roused by this recent calamity to exercise its powers more efficiently than heretofore.

THE influence on the progeny of marriages of consanguinity will be always of interest to the philosopher, to the medical statistician, and to the public at large. Whether we agree with Dr. CLOUSTON that "there seems to be a special tendency for members of *neurotic* families to intermarry, and an affective affinity amongst such that tends towards love and marriage," or with Mr. GRANT ALLEN that "what we each fall in love with individually is our moral, mental, and physical complement: not our like, not our counterpart; quite the contrary; within healthy limits, our unlike and our opposite,"—the question of intermarriage remains a debatable subject. If we were to be led to an opinion by popular prejudice or by the influence of earlier writers in France or Am[redacted] positive that the

intermarriage of relatives was an unmitigated wrong, and that nothing but evil could arise from consanguineous unions by virtue of the consanguinity.

In a paper read in the Psychological section of the British Medical Association at Brighton Dr. SHUTTLEWORTH renews an inquiry into this ever-interesting topic, and brings fresh statistics to bear on the subject. The tenour of his remarks is confirmatory in its general scope of the conclusions of others who, like himself, derived their information from the extensive field of observation provided by our idiot institutions, or from the scattered idiots who in Scotland have come under the observation of Dr. ARTHUR MITCHELL, C.B. The great difficulty in arriving at positively accurate results is the want of a uniform basis for comparison. We want to know how many healthy, self-relying men and women are the progeny of consanguineous unions in England, and it is a matter for great regret that this had not been furnished by the last census returns in accordance with the proposal of Sir JOHN LUBBOCK. Seeing that Mr. GEORGE DARWIN, by a somewhat elaborate inquiry based upon the number of "same-name" marriages, establishes as a basis of first-cousin marriages 1½ per cent. in London and 2¾ per cent. in rural districts for all classes of society, and Dr. ARTHUR MITCHELL makes his basis for Scotland 1·5 per cent., while Dr. LANGDON DOWN, on an investigation among the out-patients of the London Hospital, makes his basis ·5 per cent. only, it is obvious how greatly a more definite standard for comparison is needed.

In an investigation as to the number of imbecile children who are the products of consanguineous unions, Dr. SHUTTLEWORTH finds at the Royal Albert Asylum that 5·1 per cent. are the children of consanguineous marriages, and 2·9 per cent. of first-cousin marriages; Dr. GRABHAM found that at Earlswood 6 per cent. were the children of consanguineous unions, and 3·8 per cent. of first-cousin marriages; while Dr. LANGDON DOWN gives as his experience that, out of 852 cases of known parentage, 7 per cent. were the children of consanguineous marriages, and 5·4 per cent. were children of first cousins. Having regard to these figures alone, we can have no difficulty in agreeing with Dr. SHUTTLEWORTH that "*first-cousin* marriages (at any rate) are to some extent favourable to the production of idiot children," in spite of the arguments to the contrary based on Mr. GEO. DARWIN'S statistics. Dr. SHUTTLEWORTH, looking beyond the bald relation of numbers, and interrogating the life-history of the progenitors, corroborates in great measure what was remarked by Dr. LANGDON DOWN, that in the great bulk of the cases causes of idiocy could be discovered in addition to or independently of the consanguinity of parents. This is in harmony with the views published last year in America by Dr. CHARLES F. WITHINGTON, upholding the doctrine that morbid inheritance rather than specific degenerative tendency will account for all the infirmities met with in the offspring of cousins. It must, therefore, be that the great danger in the intermarriage of cousins lies in the circumstance that where there is a neurotic inheritance there are two certain morbid factors to contend with rather than a possible *one*. It is in this direction that the danger of consanguineous unions is to be sought. The experience of breeders of cattle teaches them that the greatest possible care is needed in [illegible] in-breeding is practised. Mr. GRANT ALLEN points out that "in narrow communities, where breeding in-and-in becomes almost inevitable, natural selection has to exert itself upon a crowd of cretins and other hapless incapables; but in wide and open champaign countries, where individual choice has free room for exercise, men and women as a rule marry for love, and marry on the whole their natural complements." On the whole, the balance of evidence would appear to be in favour of the conclusion that where a close scrutiny fails to discover any heritable weakness, neurotic or otherwise, consanguineous marriage *per se* is not necessarily a thing to be prohibited.

Is a large community the better for the existence within it of an efficient medical school? That it is so has been very eloquently maintained by the Archbishop of YORK and by Sir ANDREW CLARK at Sheffield. A church, a high-class school, a technical school, a public library, a university are unmistakable advantages. But a medical school? Might we not leave that to a few chief centres of intellectual activity—to the larger and metropolitan towns of each division of the kingdom? In these days of cheap and easy travelling why take medical teaching to the very door and home of students? When we find great metropolitan physicians and teachers like Sir ANDREW advocating the making of provincial schools great and effective, as he did last year at Dundee, and as he has just done again at Sheffield, we must believe that there is something to be said for the multiplication of provincial schools. The arguments deserve consideration. They resolve themselves mainly into two classes. Firstly, it was maintained that cultivated young men might be educated medically much cheaper at their own doors. This was the Master Cutler's great argument. Callings were wanted for young men, and they could be put into the medical profession more cheaply by the way of a good local school than by sending them to London. This is a fair argument, but not a very high one. Sir ANDREW CLARK maintained that a high-class school would be for the benefit of the community in which it was placed, and that the development of the various branches of medical knowledge and art was now so advanced that they could not be taught but in highly efficient and highly organised schools, and that it was out of all reason to expect medical men to provide and pay for these schools. We are disposed to agree with Sir ANDREW in the main. We cannot doubt that communities like Sheffield should have medical schools in which the science and art of medicine ought to be advanced by special opportunities of study and practice. English medical practice would be poorer if such lights as Leeds, Liverpool, Newcastle-on-Tyne, Manchester, and Birmingham were put out. Some provincial schools are in certain special branches inadequate. So are some of the schools in London and in other parts of the United Kingdom. There is wealth enough in all the above-named towns, as there is in London, to make the plant and apparatus of the schools complete. How is the money to be procured for these purposes? This is a question of some difficulty and delicacy. Clearly money, and teaching power, and apparatus may be wasted by too great a multiplication of schools. On the other hand, a certain amount of competition in schools is

highly advantageous. The hospitals in all our great manufacturing and industrial centres might easily be made efficient for clinical teaching—and good clinical teachers abound therein—but the great difficulty is to find well-trained anatomists, biologists, physiologists, pathologists, and chemists, who should be so well endowed as to be able to give sufficient time to teaching in a small school, and in providing them with suitable laboratories and material for the illustration of their lectures and for the practical work and instruction of their pupils. Unless this idea is held firmly in the foreground and practically insisted on, a proper medical curriculum can never be thoroughly carried out, and a medical school can only exist in name. The best schools in the provinces which have grasped the necessity of fully satisfying these requirements have increased in numbers. Leeds, Manchester, and even London are too near Sheffield for its existence as a centre of medical education, unless it puts itself in a position to compete with, or even surpass, these in the completeness of its scientific arrangements and work. Sheffield, like other places, wants some man like Mr. OWENS of Manchester, or JOSIAH MASON of Birmingham, to endow teachers and found laboratories for its medical schools. Our own great aristocratic and commercial leaders have only to reflect on the human importance of medical science to deal generously with hospitals and medical schools. The State itself might do more in assisting the costly and less immediately profitable parts of medical investigation and research. Finally, our examining authorities should be more severe in their estimate of what constitutes a medical school, and should withhold their recognition from institutions where teaching power or apparatus is deficient. In this way the number of our medical schools would be kept in check, whilst they would be fortified and improved in character. The Medical Council has committed itself to some inquiry into the efficiency of medical schools, of which we may expect to hear something at the approaching meeting fixed for Nov. 16th.

Annotations.

"Ne quid nimis."

THE GENERAL MEETING AT THE COLLEGE OF SURGEONS.

AT the general meeting of the Fellows and Members of the College of Surgeons, to be held in the College on Thursday next at 3.0 P.M., it is intended to move the following three resolutions—namely: 1. That in the opinion of this meeting, it would conduce to the welfare of the Royal College of Surgeons, and tend to promote the interests of medical polity and education, first, if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of the Council; second, if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such member for a period of ten years, (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such member for a period of twenty years, and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows. 2. That, with a view to give effect to the recommendations in the foregoing resolution, the Council be hereby respectfully requested to empower certain members of its body to meet and confer with the representatives of the Association of Fellows and of the Association of Members, together with, if necessary, an equal number of Fellows and Members who may not belong to either of the Associations, to be selected in any manner satisfactory to the Council. 3. That, in the opinion of this meeting, the method recommended by the Council for widening the basis upon which the Fellowship is obtained tends to lower the academic status of that diploma, and in the interest of surgical education is not advisable.

We are requested to state that Fellows or Members desirous of proposing resolutions at the meeting on Nov. 4th should furnish copies thereof to the Secretary of the College of Surgeons two days before the meeting.

THE ENTERIC FEVER EPIDEMIC AT SWANSEA.

HAVING completed his investigations into the circumstances of this epidemic, Mr. Ebenezer Davies, the borough medical officer of health, has now issued a report on the subject. Since the commencement of the outbreak 112 attacks and seven deaths had taken place at the date of the report. Last year a similar epidemic occurred, and during a corresponding period 277 deaths took place. But in that case the disease was distributed somewhat generally over the town, whereas this year it is limited to only two of the several divisions of the borough, and it was this limited incidence that originally led to a suspicion that the water-supply was affected, and that the mischief had been brought about by the use of a water from a special reservoir which had only been used for the supply of the districts in question. Although the actual source of the specific infection of this special water has not been discovered, yet a spring flowing into the reservoir was open to contaminating matter from a farm or farm-houses on either side of it, and from privies and pigstyes; and chemical analysis has shown it to be greatly polluted and to contain forty times the amount of albuminoid ammonia that is contained in the water supplied to other portions of the borough. The medical officer of health asserts that he not only had no acquaintance with the existence of this contaminated spring, which is almost entirely hidden along its course, but he had been told, in answer to inquiries, that the reservoir implicated was solely supplied from another source. Mr. Davies was, however, by no means satisfied that the pollution of this water was the sole cause of the distribution of the disease, and hence examination was made of the local circumstances of some of the streets which were most severely affected. The results show unventilated sewers, and arrangements as to house-drains and closets which can only be effectually remedied by applying to them the same action as is now required under the modern bye-laws with respect to all new drains and closets. In short, we imagine that the house-drains and appliances are so contrived as to facilitate the entrance into dwellings of infected sewer air from unventilated sewers receiving enteric fever discharges. Fortunately remedies are being applied, and there is every reason to believe that the epidemic is rapidly abating.

THE BRADFORD FEVER HOSPITAL.

THE Bradford Town Council have determined to adopt the recommendation of their Sanitary Committee that application should be made for Parliamentary powers to enable them to take over the local Fever Hospital; but a correspondent, writing to a local newspaper, points out that some difficulty will be encountered in carrying out the proposal to acquire the hospital. This institution, it appears, was erected years ago by the charitable people of Bradford, and the committee who have the control of it have not been asked whether [illegible] the scheme of the Cor-

poration. It has for years served to afford accommodation for all classes of patients, but those sent to it by the sanitary authority constitute the greater number; consequently, it has occurred to the Corporation that, seeing they have no voice in its management, they might as well acquire the power they desire by taking possession of the whole institution. Another reason seems to have led to the same conclusion: the Corporation were desirous that the Hospital Committee should provide a special wing for small-pox, but their request was declined, and this has doubtless necessitated the town authority taking some steps to obtain accommodation for this disease. The main fault in the proceedings appears to be the complete forgetfulness of the fact that the committee, as trustees of the funds that have been collected, are bound to see that they are properly applied, and their consent to the proposed change should therefore have been obtained in the first instance. Nevertheless, we shall be glad to hear that the transference has been effected. The primary use of hospitals for infectious cases is the limitation of infectious disease. London particularly has suffered much from this fact being overlooked. Upon the management of such institutions is dependent the question whether good or harm shall come from their existence, and their control should therefore be entirely in the hands of the authority responsible for the safeguarding of the public health.

CHEMICO-BIOLOGY OF MICRO-ORGANISMS AND PTOMAINES.

PROFESSOR POEHL of St. Petersburgh, believing that ptomaines are usually due to the action of micro-organisms in decomposing the albuminoid constituents of the body, and knowing that they themselves are of the nature of reduction products, has made a number of observations on various micro-organisms for the purpose of determining their capacity for roduction, and thus estimating their power of producing ptomaines. The substance employed for the purpose of his investigations was Koch's nutritive gelatine, to which was added a minute quantity, 0·05 per cent., of perchloride of iron and ferro-cyanide of potassium. This admixture did not, he found, interfere at all with the development of the micro-organisms. The substance was placed in a test-tube with the usual precautions, and the inoculation made with a platinum needle thrust into it. In some of these cultures a distinct formation of prussian blue from the reduction due to the development of the micro-organisms was observed along the track of the needle within from twelve to twenty-four hours. In others the blue colour was later in making its appearance, while in some no blue was visible, even after the whole of the mass had become liquefied. It was remarkable that generally the blue colour was not formed in the track within from four to eight millimetres from the surface, thus showing that the oxygen of the air is prejudicial to the reduction process. After the track of the needle had become coloured, the blue appearance began gradually to spread around it in the substance of the gelatine, but even after a week an uncoloured superficial layer was always present of from four to eight millimetres in thickness. The chemical formation of prussian blue requires the presence of a slightly acid condition, and as some of the micro-organisms refuse to develop except in a slightly alkaline medium, the difficulty had to be overcome by waiting until the development had taken place in the slightly alkaline gelatine, and then adding nitric acid, when, if reduction had taken place, prussian blue was formed. Comma bacilli, typhus bacilli, streptococci, many of the micro-organisms of the fæces and the sputa, and of those existing in the Neva and waterworks water, set up a considerable degree of reduct[illegible] including Bacillus subtilis, showed no signs of doing so even after a week had elapsed. In the case of cholera and other bacilli in alkaline media, Dr. Poehl observed that the addition of hydrochloric acid to the culture in process of development gave rise to a red pigment of the same tint as acetate of iron, in addition to the formation of prussian blue. A similar pigment was formed by itself in control experiments made with the same bacilli and nutrient gelatine containing no iron or ferro-cyanide, and is probably, according to Dr. Poehl, identical with the scatol derivative found by Brieger in pathological urines. The bacilli of Prior and Finckler found in cholera nostras appear to require much less oxygen for development than the comma bacilli, which are in a high degree aerobic. It would seem that in true cholera oxidising medicines, as peroxide of hydrogen and peroxide of manganese enclosed in keratin, so as to act specially on the small intestine, might be expected to act both in destroying ptomaines and in preventing their formation. Dr. Poehl thinks that much practical information is to be obtained by chemico-biological investigations on comma bacilli and pathological micro-organisms generally.

THE EASTERN HOSPITAL.

DR. COLLIE'S annual report for the year 1885 gives an interesting account of the work of the hospital during that period. Altogether 1038 patients were under treatment, 843 of whom were admitted during the year. Of these, scarlet fever contributed 614 cases, and enteric fever 112 cases, the mortality per cent. of these diseases being 12 for the former and 19 for the latter; typhus fever had a mortality of 46 per cent. In the small-pox wards 618 patients were admitted, of whom 425 were vaccinated; in 91 the vaccination was doubtful, and 102 were confessedly unvaccinated, the general mortality per cent. being 22·6 for this disease. Dr. Collie observes that the number of admissions of cases of enteric fever was less than in any year since the opening of the hospital in 1871. It is interesting to note that two nurses contracted enteric fever. It will be recollected that Dr. Collie some years ago contributed a series of valuable papers on the communicability of this disease, and argued against the belief that any insanitary condition of the hospital was responsible for the infection of the nurses which from time to time took place. Since these papers were published, the drainage and sanitary arrangements have been entirely reconstructed under the supervision of Mr. Keith Young, and may now be considered to be as perfect as they can be made. That the nurses have still continued to suffer from enteric fever is strong evidence of the correctness of Dr. Collie's view, that the youth of the nurses employed in the institution is an important element in rendering them susceptible to this disease.

NO MEDICAL EVIDENCE.

ON September 28th an inquest was held by Mr. F. S. Hawthorn, deputy coroner, on the body of George Ridley, aged thirty-seven. Deceased was found in an insensible condition on the Midland Railway with a scalp wound in the right occipital region and a small compound depressed fracture of the skull. He was removed to the Burton-on-Trent Infirmary, where trephining was performed. Death ensued, however, without deceased having recovered consciousness. No medical evidence was called. The jury returned a verdict of "Accidental death while trespassing on the railway." We entirely demur to the course taken in the investigation of the above-mentioned case, and to the verdict which followed the evidence. It seems to us a matter of doubt whether the death was accidental, suicidal, or homicidal. Except for the fact that the man was in a place of danger to life and limb there was nothing to show how the

injuries were received, for "the railway officials had been unable to trace the train by which the deceased was struck." A careful search ought certainly to have decided the latter question. The means by which any further light could reasonably be expected to be thrown on the matter—viz., a post-mortem examination—was not employed. We are decidedly of opinion that wherever the cause of death is equivocal, and especially where the liberty of another person may be imperilled by suspicion of foul play, it is the bounden duty of the authorities to secure the best attainable evidence, and this can only be got in cases like the one under consideration by a carefully conducted necropsy.

THE VENOM OF POISONOUS SNAKES.

THE investigation of the poison which in the form of snake-bites kills nearly 50,000 human beings per annum in India alone, cannot fail to present many points of interest, and has just been undertaken by Dr. R. Norris Wolfenden, whose results are published in the last part of the *Journal of Physiology*. The poisons with which he experimented were obtained from the Indian cobra, the scientific name of which is Naja tripudians, and the Indian viper, named the Daboia Russellii. In the report of the last Snake Commission, Dr. Wolfenden tells us, Mr. Pedler, one of the commissioners, sums up the results of his chemical examination into the nature of the poison with the remark that it is quite impossible to draw any deductions as to its nature, and he thought it was more than possible that the poison was a mixture of albuminous principles with some specific poison. Sir Joseph Fayrer and Dr. Lauder Brunton compared the action of cobra poison to the alkaloid conia. Blyth thought that the poison could be separated from the proteids in the venom, and that it was not thrown down with the albumens on the addition of alcohol. Walls, however, with whom Dr. Wolfenden agrees, ascertained that this is an error, and attributable to the circumstance that the alcohol used was not sufficiently pure. If to a solution of cobra poison absolute alcohol be added, a white precipitate is thrown down. After the precipitate has been thoroughly washed with alcohol, it can be redissolved in water, and the solution produces all the effects of cobra poison. Moreover if dried cobra poison in a state of fine powder be added to absolute alcohol, and the mixture be frequently agitated, the alcohol will derive no poisonous property from the cobra venom; but if rectified spirit be employed, the water in the rectified spirit is capable of taking up a certain amount of the poison. This is just what might be expected of an albuminous fluid, and tells in favour of the view that the cobra venom is of a proteid nature. The observations and experiments of Weir Mitchell and Reichert upon the venoms of several American snakes tend to prove that the poisonous principle is resident in the proteid constituents. Dr. Wolfenden finds the venom is generally acid when quite fresh, but that it may become neutral when it has been kept for a few hours. Experiment showed that dialysates of the venom, free from proteid, were quite harmless; but that if they contained any proteid they became toxic. The activity of the venom, though reduced, is not entirely abolished by the exposure to a boiling temperature. It is rendered innocuous by the permanganate of potash outside the body, as well as by tannic acid, metallic salts, and other agents which precipitate albumen. The albumens which Dr. Wolfenden finds are present in the venom of the cobra are: First, a globulin, which is always present, and probably kills by interference with the respiratory mechanism—that is, by asphyxia, and without paralysis, causing local inflammation, but not of great intensity. Secondly, an albumen resembling acid albumen, which is precipitated, together with globulin, by saturation, and which is in some degree dialysable; this proteid probably acts on the respiratory apparatus chiefly like the globulin, but less intensely. Thirdly, an albumen which is precipitated sodium sulphate out of the magnesia filtrate, and appears to be serum-albumen; this is also toxic, and produces a kind of ascending paralysis, with fatal termination by suppression of the respiratory function due to paralysis of the respiratory muscles. Lastly, he found some traces of hemi-albumose and of peptone. Similar compounds were found in the venom of daboia.

THE RIVER LEA.

DR. TRIPE, the medical officer of health of Hackney, is wisely exercising watchfulness over the river Lea. Public interest in any subject cannot be maintained for any length of time, and officers are often powerless to procure remedies for great evils except when popular feeling is aroused. We make no excuse, therefore, for again directing attention to the condition of this river, and to Dr. Tripe's statement that it has "gone back almost to its former state." Up to the end of September the Tottenham Local Board had been permitted by the Metropolitan Board of Works to discharge the Tottenham sewage through a new sewer into the metropolitan system, but this privilege has now ceased, and we learn from a report which Dr. Tripe has presented to his authority that he found a scum on the water near the Tottenham outfall, and many dead fish. Within fifty yards from this outfall there was as much ammonia and organic matter in the water as to equal a mixture of one-third of sewage and two-thirds of distilled water, and on one particular day the effluent contained as much of these constituents as did sewage taken from the sewer in Mare-street, Hackney, and it smelt worse. A member of the Hackney vestry, who is also a member of the Metropolitan Board of Works, expressed the opinion that further assistance from the latter Board could not be expected, and that the only remedy was in the hands of the Tottenham authority, who must deal more effectually with their sewage before discharging it into the Lea. Finally, Dr. Tripe's recommendation was adopted, that the attention of the Tottenham Local Board and the Lea Conservancy Board be called to the unsatisfactory condition of the Lea, since the effluent has again been discharged into that river.

INTRA-CRANIAL HÆMORRHAGE.

AT a meeting of the Pathological Society of Philadelphia, Dr. H. A. Formad read a paper upon Intra-cranial Hæmorrhage (*Boston Medical and Surgical Journal*, Sept. 30th), based upon an analysis of 143 cases occurring in medico-legal practice. He divided them into eight classes, and arrived at the following practical conclusions:—1. Hæmorrhages exclusively above the pia mater and above the dura mater—that is, on the outside of the brain—are always due to *traumatism* or to *sunstroke*, provided a cerebral source for hæmorrhage be excluded, and the cerebral vessels and membranes be not diseased. 2. Hæmorrhage in the floor of the fourth ventricle is always traumatic, provided there be no blood clots in the lateral ventricles or any other part of the cerebral substance. 3. Hæmorrhage exclusively below the pia mater, or in any part of the brain substance, or in the ventricles (except the fourth), is always idiopathic—that is, due to disease. 4. There must be a diseased condition of the cerebral vessels or substance for hæmorrhage to be a result of disease. There must be traumatism (a fall or violence) to account for a hæmorrhage in a normal brain. 5. The blood clot in concussion of the brain is not found at the point of application of violence, but always somewhere about the opposite side of the brain, and always within the arachnoid—that is, between the pia [illegible] The blood clot in fracture

of the skull is always found at the point of application of violence immediately below and always between the dura mater and the fractured part of the skull itself. 7. A blood clot found within the cranial vault is more favourable to the patient if due to fractured skull than if due to a mere concussion. 8. Only clotted blood and infiltration of blood corpuscles into tissues indicate an ante-mortem hæmorrhage. Liquid blood is due to post-mortem oozing, and stains, but does not infiltrate, tissues. 9. Severe bruises and cuts of the scalp may be seen in cases of idiopathic apoplexy, when a sudden cerebral hæmorrhage causes a person to fall. 10. In some cases it is impossible to decide by medical examination alone as to whether a head injury and the resulting hæmorrhage is due to a fall or violence. 11. External marks of violence may be invisible to the unaided eye in some cases of injury to the head or other parts, but are easily detected and distinguished from post-mortem spots by means of the microscope. 12. The bulk of an intracranial hæmorrhage stands usually in inverse proportion to that of the external scalp hæmorrhage.

HYDROPHOBIA IN CALIFORNIA.

THE San Francisco *News Letter* is publishing the replies which have been received from members of the medical profession in regard to the non-appearance of rabies in California or on the Pacific Coast. The two questions to which answers were solicited were as follows: (1) Has any case of rabies, either in man or animal, come under your personal notice, in this State or on this coast? If so, please give particulars. (2) Have you any theory as to the cause of the absence of this disease from our midst, and have you any facts to sustain your theory? The replies appear to prove pretty conclusively the non-existence of the disease in the district respecting which inquiry is made. One correspondent during a residence of twenty-nine years has seen but one case; the others unanimously answer the first query in the negative. With regard to the second question there is not such a similarity of opinion. One attributes California's immunity to its climate, while another gives as his opinion that the absence of rabies does not seem to be accounted for on the basis of climatic conditions. One alludes vaguely to the intervention between the east and the west of vast arid plains, lofty ranges of mountains, and great rivers, which he surmises present insuperable obstacles to infection by the direct transportation of infected animals; whilst another gravely states that the only theory that presents itself to him "is that, however hot the days may be in California, the nights are always cooler." Whatever may be the cause, however, California is to be congratulated on the effect, and will, we hope, continue to remain free from the scourge which has within the last few months so severely afflicted our own country.

DEATH FROM EATING HAW-BERRIES.

AN inquest was held by Mr. E. A. Carttar on Oct. 16th touching the death of Emma Ponton, aged seven years. Deceased had eaten a quantity of haws—the fruit of the whitethorn (*Cratægus oxyacantha*). On the following day she became very ill and vomited. A medical man was called in, but despite his efforts the girl died two days later. Dr. M'Mahon attributed the death to "suffocation arising from inflammation of the stomach and bowels caused by excessive nervous irritation, brought on by the swallowing of the seeds of berries which were not poisonous." As the coroner observed, it was a remarkable death. Apart from the suffocation induced as alleged, however, we can quite understand that the haws may have caused death. In the first place they are astringent and somewhat acrid, and are not unlikely, when eaten [illegible] to bring up vomiting and gastro-intestinal irritation. Further, the dense outer skin and the "stones" may excite digestive disturbances by their mechanical action. Accumulations of such bodies may lead to fæcal impaction, or a single stone may readily be lodged in the vermiform appendix, and lead to ulcerative perforation, with retro-peritoneal abscess and peritonitis as sequelæ. From the evidence it does not seem certain that deceased may not have swallowed other "berries" of a poisonous nature in mistake for haws—e.g., the fruit of the bryony plant, which when ripe is found in scarlet clusters, one of the most beautiful ornaments of our hedgerows; or of the woody nightshade (*Solanum dulcamara*). The unfortunate event shows the necessity for instruction to the young of the danger that lurks in the ingestion of wild "berries," whether reputed to be poisonous or harmless.

METROPOLITAN ASYLUMS BOARD.

AT the fortnightly meeting of the Managers of the Metropolitan Asylums District, which was held on Saturday last, the Board considered a letter from the Local Government Board asking what steps were being taken to remedy the defective drainage of the Western Hospital, and it was decided to refer back to the committee of the hospital their report recommending that a firm of architects be employed to carry out the work, and that the committee be empowered to consult a sanitary engineer if they considered it necessary to do so. The returns of those under treatment showed a total of 622 patients, of whom 520 were suffering from scarlet fever, 99 from enteric fever, and 3 from small-pox. Scarlet fever and enteric fever showed a slight tendency to increase, but the metropolis continued almost free from small-pox. The committee for the Western Hospital reported that they were of opinion that the practice of disinfecting the Board's ambulances at the hospital should be discontinued, while the Northern Hospital committee reported in an opposite sense. The arrangements for the lighting of the hospital ships by electricity are now completed.

THE BIARRITZ CONGRESS ON CLIMATOLOGY.

MORE than a thousand adherents were secured by the organisers of the above Congress. Several Governments sent representatives, and the presence during the month of October of so many distinguished guests at Biarritz, helped to enliven this fashionable watering-place. There are few seaside resorts in France better situated than Biarritz, and under the Third Empire it was often frequented by the Court and the highest functionaries of the State. In the intermediary seasons, during the late autumn and the early spring, Biarritz is an invigorating "half-way house" between the north and the south. It does not, therefore, compete with the Riviera, but helps rather to supplement the climatic advantages found on the shores of the Mediterranean. Indeed, a whiff from the Atlantic is always welcome to patients from the north, and this can be safely enjoyed at Biarritz at a season when it might prove fatal nearer to England. As if in acknowledgment of the alliance between Biarritz and the Riviera, Dr. Colignon, chief physician of the Hôtel Dieu at Monaco, was elected by the Congress secretary for the principal section—namely, that dealing with scientific and medical climatology. Effectively the principality of Monaco occupies the most enviable site on the Riviera. The shelter enjoyed from the northern winds is not surpassed anywhere. Further, a certain portion of the principality—that stretching towards the Eastern frontier, and known as the Quartier des Moulins, where the lemon trees blossom all the year round—is not only marvellously sheltered, but does not suffer from stagnant atmosphere. Situated on the ledge of a high mountain, dominating the sea,

it is sufficiently elevated to enjoy a constant breeze without losing its advantages of temperature. Dr. Colignon doubtless made a good point of these qualifications, and we are informed that his statistics concerning the cures effected at the Monaco Hospital were considered very conclusive by the Congress. Full reports of the proceedings have not yet been published, but we can nevertheless congratulate the town of Biarritz on the initiative it has taken. The climatic treatment of disease is yearly becoming more general, and all efforts to collect and scientifically compare the results attained will render this mode of dealing with a numerous class of patients easier to follow, without incurring the dangers that spring from insufficient knowledge of local peculiarities.

PURPURA HÆMORRHAGICA IN ST. PETERSBURG AND HAMBURG.

DR. E. MASING compares (*St. Petersburger Medicinische Wochenschrift*, Nos. 39 and 40) a case of purpura hæmorrhagica of his own, together with 13 cases culled from the case-books of the Mary Magdalen Hospital in St. Petersburg, with the 73 cases collected by Dr. Scheby-Buch, from the records of the Hamburg General Hospital. Of the 14 Russian cases, 10 were complicated with pyrexia and 8 with diarrhœa. Eight presented painful and swollen joints and muscles, whereas in the 73 Hamburg cases only 27 are reported as having had rheumatic symptoms. Hæmorrhage from the nasal and other cavities of the body occurred in 6 cases—i.e., in about the same proportion as in Hamburg. Urticaria was not observed at all, though it was frequently present in the Hamburg series. Youth is the most common time for the disease to occur, 9 cases being under twenty-five years of age. The disease would appear to be even more rare in St. Petersburg than in Hamburg, for there were only 13 cases found in the Mary Magdalen Hospital Reports for the last twenty years, during which time the total number of patients was over 82,000; while the 73 Hamburg Hospital cases occurred in the space of forty-one years out of a total of 100,000 patients. The mortality was greater than in Hamburg, 4 out of 14 being fatal in St. Petersburg and only 10 out of 73 in Hamburg. One of the former series, however, died of phthisis. The author is quite unable to throw any light on the etiology of hæmorrhagic purpura, but he expresses the hope that bacteriological research may help to clear it up.

ERGOTISM IN COWS.

SOME discussion has been taking place lately with regard to ergoted grasses producing abortion in cows, and the question does not yet appear to be answered as to whether and to what extent the accident is due to the Claviceps purpurea, which in some seasons is a very common parasite on the herbage of pasturs. By some authorities it is believed that ergot is the cause of the widespread epizootics of abortion which are sometimes reported as occurring among cattle, and which cause heavy loss to stock-breeders. By others this effect of ergot is doubted, and these doubts would appear to be justified by very conclusive evidence of an experimental kind. It has been given in large and repeated doses to cows, bitches, cats, swine, and rabbits in all stages of pregnancy, but its ecbolic action has not been observed in them, and the conclusion arrived at was that amongst the lower animals ergot, whether given by the mouth or rectum, in single large doses, or for some time continuously, has no tendency to expel the contents of the uterus at any period of gestation. Abortion in cattle is undoubtedly due to many causes. When sporadic, it may follow injury or disease; but when it occurs in a herd of pregnant cows, all or nearly all aborting after the first case, then the occurrence looks mysterious, and is popularly believed to be owing to "sympathy" among the cows, a kind of imitative action brought about by the animals' imagination. This notion has, of course, no foundation in fact, and multiple cases of abortion can be truthfully accounted for by infection conveyed from one cow which has aborted to others which are in calf. Veterinary surgeons had long, from observation, come to the conclusion that septic infection, possibly through the genital organs, was the principal if not the sole cause; and some years ago Franck, of the Munich Veterinary School, made some interesting experiments on pregnant cows, which demonstrated that abortion could readily be brought about by introducing a very small quantity of matter obtained from the vagina or afterbirth of a cow that had slipped its calf into the vagina of a pregnant one. This matter was found on examination to teem with micrococci. In order to prevent outbreaks of abortion, viewing it as an infectious disease, cattle-breeders should be thoroughly aware of the premonitory signs, which are usually well marked, and at once separate the animal which shows them from its fellows. When the accident has happened in a cowshed, then measures of a sanitary kind should be speedily adopted, as if dealing with a most infectious malady. By acting in this way, the heavy losses which are so frequently reported as the sequel of "warping" would be no longer heard of.

THE SUCCI FAST.

THE "fast of Succi" is commented on with unsparing sarcasm by M. Loye in the pages of our contemporary, *Le Progrès Médical* (Oct. 16th). He has been surprised to see that the physicians who had the control of the "experiment" allowing Succi to receive visits, to take rides, baths, &c., and, in fact, to have a measure of freedom which would have discredited the researches of Chossat and Voit, or Bidder and Schmidt, had they allowed it to the animals on whom they studied the effects of inanition. The whole affair seems to him to be a juggling trick, aimed to mystify *messieurs les savants*. But what, he asks, was the object in view? Was it to demonstrate the absolute possibility of living without nourishment—to do work without any source of force? That would have been a new search after perpetual motion, and he would not insult his readers by discussing it. Was it to show that certain individuals can do without food for some days? That is a common physiological fact, of which there are numerous instances, from the germinating grain to the hibernating marmot. Was it due to the faculty of simulation, which has too often upset the most clever *savants*? M. Loye hints even that such suspicion may reasonably attach to the Italian fasting man, who had formerly suffered from mental alienation. The results of the fast confirm these latter suspicions, for, apart from loss of weight and diminution in urea, he showed no symptoms of inanition; there was no loss of muscular energy; the respiratory movements and cardiac pulsations were as frequent as at the commencement. The physicians in charge do not appear to have measured the work done—a grave omission, which if supplied would have enabled one to determine whether or not there had been any introduction of food. The experiment thereby loses all scientific value. He only lost in weight 441 grammes per diem, and can it (the writer asks) be seriously maintained that this amount could suffice to maintain life and produce so much work? Bidder and Schmidt's animals lost $\frac{1}{7}$th of their weight daily with hardly any work; Succi only lost $\frac{1}{13}$th of his body weight, and yet took long walks, swam, conversed, and performed all manner of work. Finally, M. Loye discredits the famous liquor which Succi took to assuage his hunger, for the sensation is central, and not to be [illegible] anæsthesia of the stomach. He

regrets that his Italian *confrères* should have accepted the office of detecting a trick, which is the business of conjurors and not of doctors; and he concludes by trusting, for the honour of French science, that the further challenge be not accepted.

THE SCOTCH AND IRISH ELECTIONS.

WE think the merits of the Scotch candidates are now well understood. Dr. Morton's personal qualifications are unexceptionable, but no ingenuity will get rid of the argument that he is disqualified to represent the free practitioners of Scotland by the mere fact that he is the President of one of its corporations, already strongly represented in the Council. It is an open secret that several distinguished physicians—notably, Sir Douglas Maclagan and Professor Gairdner—have been mentioned as gentlemen who would have had a large support as honoured members of the profession in Scotland. It is understood, too, that either of these gentlemen would have regarded it as an honour to be elected direct representative for the northern division of the kingdom. But they judged that, strictly speaking, the seat was meant for men representing the rank and file of the profession, and so judging, they decided not to complicate the election by allowing their names to be put forward. We venture to say that by this decision they have done great honour both to themselves and the general practitioners of Scotland, who are now free to elect one of their own number. Two such gentlemen are before the constituency, and we look confidently forward to the election of one of them. Dr. Sinclair of Dundee or Dr. Bruce of Dingwall would worthily represent the practitioners of Scotland. It speaks well for the public spirit of this section of the profession that men in busy practice can be procured ready to make the necessary sacrifice of time and convenience. The case of Ireland is to be regarded with more anxiety. Dublin threatens to seize the new seat as she has appropriated all the rest since there was a Council, and general practice in Ireland, which has so many wants of its own, appears likely to go as unrepresented as if direct representation had not been granted. Let us hope that even yet the official and consultant and Dublin candidates will leave the seat for those who sorely need it. But this "sublime repression" of themselves is not to be relied on too much, and, as in Scotland, the blame will ultimately rest on the general practitioners if they do not elect one of their own order.

PERNICIOUS ANÆMIA AND INTESTINAL PARASITES.

THAT the condition produced on the system by the ravages of the blood-sucking parasite, Anchylostomum duodenale, resembles in every particular the progressive anæmia which so often proves fatal, and is, so far as knowledge goes, at once idiopathic and pernicious, is now a well-established fact. It has remained, however, for the past few months to see statements made and proofs advanced that other intestinal parasites may be the means of inducing this grave anæmia. We lately cited the paper of Dr. Reni on the relation of Tricocephalus dispar to Beri-beri, which was intended to point to this connexion; and a paper was lately published by Dr. Reyher to prove that in some cases the cestoid worm, Bothriocephalus latus, is the cause of a "pernicious anæmia." (An abstract of this paper will be found in the *International Journal of the Medical Sciences* for October, p. 531.) Dr. Runeberg, of Helsingfors, read a paper at the Berlin Congress of Naturalists and Physicians in confirmation of Reyher's view. (*Berl. Klin. Wochensch.*, Oct. 4th.) He averred that under certain circumstances the presence of bothriocephali in the intestine might lead to true pernicious anæmia; he had observed this connexion in twelve out of nineteen cases, and was able [illegible] patients by the free use of anthelmintics together with arsenic and iron. In the debate that ensued, Professor Biermer doubted if Dr. Runeberg's cases really came under that category, not presenting all its typical phenomena. He had never himself met with any such connexion with intestinal worms. Professors Quincke, Immermann, and Heller all spoke in the same sense, the last-named pointing out that bothriocephalus was a common parasite, and often met with in great abundance without inducing any general symptoms.

THE CHOLERA EPIDEMIC.

THE past week has exhibited a further decline in the extent to which cholera has prevailed in localities which have already been referred to as suffering from the epidemic. Trieste and Pesth are now the only two places from which regular daily returns are received. As regards Trieste, the daily mortality during the past week has varied from 4 to 1; and at Pesth it has varied from 18 to 10. But, quite apart from these towns, it is evident that cholera is still somewhat widely diffused over various parts of Austro-Hungary, and recent information is to the effect that in Croatia an average of 12 attacks and 6 deaths, and in Szegedin an average of 13 attacks and 7 deaths, still occur daily. Fresh occurrences of cholera are also reported from Raab, Theriosopol, and the village of Csebza in Southern Hungary. During the seven weeks ending Oct. 24th the cholera deaths in Pesth had amounted to 393, and it is estimated that the attacks had exceeded 1000.

"AEROBIC" AND "ANAEROBIC."

A SUGGESTIVE idea, which has not yet led to any definite results, has been taken up by M. Arloing, and concerns an attempt to learn more of the nature of infective diseases by the aid of chemical physiology. The aerobic microbe, it is believed, would live at the expense of the oxygen of the blood, and we should consequently expect that this would show itself in the form of alterations in the quantity and quality of the chemical substances discharged from the body. It has been found that the amount of carbonic acid discharged from the lungs in cases of charbon and gangrenous septicæmia diminishes during the whole course of the fever, and especially towards its termination. This diminution in the discharged carbonic acid appears to have begun soon after the inoculation of the poison in the case of charbon; whilst in the case of gangrenous septicæmia, for some hours after the inoculation the quantity of carbonic acid exhaled was increased. It is believed that this difference in the amounts of carbonic acid discharged during the hours immediately following inoculation is to be attributed to the difference between aerobic and anaerobic organisms.

THE ADVANCE OF TEMPERANCE.

MOST of our readers will be pleased to see that, under the action of healthy public discussion, temperance is becoming more and more a custom with our countrymen. Alcoholic drinks, which once were classed with daily bread in very many households, rich and poor alike, are now luxuries less common than tea, and have, indeed, in an ever-widening range of popular opinion, come to be no more than the stimulant accessories of impaired nutrition. They certainly should not, as a rule, be taken apart from food, and neglect of this precaution has probably much to do with the formation of the drinking habit. We have heard it suggested, in conformity with this view, that licensed houses should be required to supply food as well as intoxicant liquor, and it is possible that in that case the consumption of the latter would be less than it is. Every means of restraining drunkenness is helpful to the

cause of temperance, therefore we willingly note the suggestion. At the same time, it should be remembered that there is not for those whose health is good much help, if any, in alcohol, that it rather hinders than assists their energies, and that non-stimulant restoratives and food can best recruit them after toil; while thirst, the want of water, is best allayed by merely making good that want.

LIGATURE OF ARTERIES.

PROBABLY few subjects have afforded more occupation to the surgical mind than that of the ligature of arteries, and there seems a probability that it will continue to exercise the ingenuity of surgeons for many years to come. The discussion at the last meeting of the Clinical Society, though it did not elicit the opinions of many surgeons, yielded at least a great variety of opinions, for no two speakers appeared to agree in all particulars. The material of which the ligature should be composed, the kind of knot to be used, whether the arterial coats should be divided, whether two ligatures should be employed and the artery divided when deligation is practised in the continuity of an artery—are all moot points. Mr. Thomas Smith advocated the employment of the clove hitch, as being less liable to slip or to cause ulceration of the artery than the ordinary reef-knot, which has been in almost universal use of late years. The absence of any necessity for division of the internal coats of the artery seemed to be proved by the experimental researches of Messrs. Ballance and Edmunds. Kangaroo tendon does not yet seem to have established its reputation as a ligature to be relied upon in all cases.

THE INDISCRIMINATE SALE OF FIREARMS.

ON Thursday last Dr. Danford Thomas held an inquest on Edgar Wilkins Hanley, aged thirty-one, an artist, who shot himself on the previous Monday. Mr. Sylvanus Hanley, the father of the deceased, stated that for several years his son had been under medical care for a series of nervous disorders, and he had an idea that he would die an idiot. Last February he was strangely affected by the suicide of the late Lord Shaftesbury. He was attended by his landlady, and also an attendant. At four o'clock on Monday the deceased shot himself, a revolver being found afterwards by the bedside. Since Christmas last, a friend had intercepted letters from the deceased to various London gunsmiths asking to be furnished with firearms and ammunition. One gunsmith insisted on complying with the order, whereupon witness threatened to put the matter into the hands of Sir Charles Warren. A juryman remarked that greater care ought to be exercised in the sale of firearms to invalids. They should not be sent in this manner indiscriminately by post. The coroner said, "All the gunsmiths want is the money. They will evidently send revolvers by post to anyone." A verdict of "Suicide whilst of unsound mind" was returned. We must express our approbation of the remarks above quoted. Any infant, any lunatic at large, in fact any irresponsible person, can, as the law at present stands, furnish himself with a weapon by which he can in a moment deprive himself or others of life. Such a state of things surely ought to be remedied. We would suggest that no person should, under any circumstances, be allowed to purchase firearms of any description except on a personal application to the gunsmith, accompanied by a written statement concerning the purpose for which such weapons were required; and that, moreover, such statement should be accompanied by a guarantee from a householder, or some responsible person, that he believes the weapon in question is to be used solely and *bonâ fide* for the purpose stated. Within a few years back we can recall to memory cases of a boy who killed another with a pistol, of a girl playing with a friend's revolver who shot herself through the heart, of a man who shot a woman through the chest, of a nobleman who shot himself in a cab, and many similar cases. These facts speak for themselves, and the mere mention of them ought to be sufficient to awaken the minds of the authorities to the necessity for legislation on so important a subject.

PUBLIC HEALTH IN THE KINGDOM OF HAWAII.

FEW things are more significant of the progress which is going on all over the world than the establishment in countries not long removed from a state of barbarism of boards of health and of organisations for securing efficient sanitary administration, such as were all but unknown even in the most civilised communities during the past century. The kingdom of Hawaii is eminently a case in point, and we are glad to find that, as the result of the efforts going on there, a manifest decline in the death-rate is in progress, and that the Hawaiian people are gradually being awakened to an appreciation of the laws of health in many ways. The President of the Board of Health, in his report for 1885, the thirteenth year of the reign of his Majesty Kalakaua, speaks in the most hopeful terms of the future of the kingdom, and he expresses the conviction that a race so vigorous in its rude uncultivated state, so healthy and prolific in its aboriginal condition, will not be overcome by the vicious conditions connected with the radical change in habits of life and manners which is being brought about by the transition from a simple natural life to that of the more artificial one of civilisation. Great improvements are in progress as to the treatment and care of lepers. It has been deemed necessary to separate from others the children of lepers, although not yet attacked with the disease. But latterly it has been admitted that it is little short of an outrage that children, only suspected of being tainted on the ground of heredity and yet giving no sign of the disease, should be doomed to lose all their opportunities in life and to associate only with lepers. The result is that a special school for girls has been opened by the queen, and a hope is expressed that a similar institution may be erected and opened by the king for the boys. The water-supply for some principal towns has been largely improved; the question of hospital construction generally is being considered; and it is urged that means of isolation in cheerful breezy spots should be provided for infectious diseases, and that the question of drainage should be attended to. As to the importation of infection, a form of quarantine detention is largely trusted to, and the accommodation available seems to be more complete than that existing in some European communities where profession of trust in the same expedient has long existed; thus it was tested last year when 940 Japanese immigrants suffering from small-pox were landed; and no Chinese are allowed to come ashore except after a quarantine detention.

NEURITIS AND NEUROSES.

THE growing conception of "neuritis" as an entity and a frequent cause of disease is leading to the explanation of several functional derangements which hitherto have been classed under the wide but meaningless term of "neuroses." Dr. Max Meyer adduces evidence to show that even when "multiple neuritis" is exhausted to explain alcoholic and toxic paralyses, there remains the large group of peripheral neuralgiæ which may have their starting-point in a neuritis; and that motor spasms, tic douloureux, migraine, and even epileptic attacks may sometimes be referred to the same source. (*Berlin. Klin. Wochenschrift*, No. 43.) He illustrates his thesis by cases of sciatica, occipital neuralgia, migraine, epilepsy, and tic [redacted] which there was distinct evi-

dence of neuritis; and we need hardly adduce the well-known fact of tender points in many neuralgiæ which bear this out. Granting this inflammatory origin, it points, he thinks, to therapeutic measures—in rigid antiphlogosis (i.e. leeching) at the outset, whereby may be avoided relapses or secondary degeneration of the affected nerve. If the acute stage have passed, he considered that the best measure for promoting absorption of the inflammatory condition is galvanism, with which may be combined massage; and that, lastly, nerve-stretching is of value in cases where there is old exudation in the nerve sheath and its vicinity in spots which are not accessible to galvanism.

PROFESSOR RUTHERFORD ON THE SENSE OF HEARING.

IN the introductory address at the Edinburgh University on the Sense of Hearing, Professor Rutherford discussed at considerable length the theory of sound sensation which was advanced by Helmholtz, and the theory of the cause of concord between tones of the same pitch. According to Helmholtz, a compound vibration is analysed in the cochlea. If the blending of each sensation in a compound sound eventually takes place in the centre of perception, why, Professor Rutherford asks, is there any need to have the complex vibration analysed in the cochlea? Those of our readers who are interested in this matter we must refer to Professor Rutherford's suggestive address.

VISCERAL TABES.

IF one were asked the meaning of "visceral tabes," the reply would probably be given, without suspicion of being wrong, to the effect that the term implied a wasting of the internal organs of the body. But, alas, visceral tabes has no such meaning. The origin of the designation may be thus sketched: locomotor ataxy is called tabes dorsalis, and sometimes plain "tabes"; visceral crises are remarkable symptoms of tabes dorsalis; a case of locomotor ataxy in which the chief features are the occurrence of visceral crises, is termed visceral tabes. Bronchorrhœa, gastrorrhœa, and entorrhœa are the visceral symptoms most marked in a case of "visceral tabes," recorded in No. 117 of *La France Médicale* by M. Seglas. In addition to the "runnings" from the bronchi, stomach, and intestines, the patient was the victim of profuse perspirations and copious discharges of urine. The patient is a female, aged fifty, whose father died from disease of the spinal cord, and whose two sisters and one brother also succumbed to paralysis. The knee-jerk is lost only on the right side. The ataxy of gait is not marked, but there is inability to walk well in the dark.

PERLÈCHE: AN AFFECTION OF SCHOOL CHILDREN.

AN affection which is common among school children in parts of France, and which is known by the names of *perlèche* and *bridou*, has recently been investigated by Dr. Justin Lemaistre, professor in the Limoges School of Medicine, and found to be of parasitic origin. The parts affected are the angles of the mouth and the skin immediately adjacent to them. The epithelium first becomes whitish, sodden, and easily detached; the skin then becomes involved, but as a rule only the superficial layers of the epidermis peel off, the corium not being quite denuded. Sometimes small fissures make their appearance, radiating from the angle of the mouth, which occasion some pain and bleed slightly when the mouth is widely opened. The appearance is not unlike that of the mucous patches and rhagades seen in the same situation in syphilitic children. The average duration of the affection is not more than a fortnight, but children are often affected several times [illegible] no protection is afforded against subsequent attacks. Of course it is only of a slight nature at any time. M. Lemaistre finds that it is contracted through the vessels from which the children drink. He examined the epithelium and found a new microbe belonging to the sphero-bacteria or cocci of the Schizomycetes group. Cultivations in bouillon produced a mass which gave the appearance of an immense number of chains intertwined; consequently M. Lemaistre proposes the name Streptococcus plicatilis. He succeeded also in cultivating the same from the water of a fountain. The wooden drinking bowl in use amongst the poor plays, he thinks, an important part in the etiology of the disease. He explains the situation of the affection by supposing that the Streptococcus plicatilis is anærobic, and that it finds in the commissures of the lips suitable moisture and sufficient protection. Fortunately it does not multiply very rapidly, and consequently the affection it produces is not of a serious nature. Of the 5500 children in the thirty-two primary schools in Limoges, 312, or one in every 17, are affected with perlèche. The best treatment is by means of copper and alum applications, boracic acid appearing not to be efficacious. The prophylaxis consists in cleaning the drinking vessels and fountains. Though no attempts at inoculation seem to have been made, the researches of M. Lemaistre leave but little doubt of the parasitic nature of this essentially school affection, which very probably is common enough, and may usefully be looked for by rural practitioners in this country as well as in France.

THE CARDIAC GANGLIA.

DR. LUDWIG EISENLOHR, assistant at the Munich Pathological Institute, has recently described the nerves and ganglia of the human heart (Abstr. in *Münchener Med. Woch.*, No. 39). He describes ganglia cells occurring isolated and in groups, mainly in the auricular wall, more rarely in the auriculo-ventricular groove. They lie embedded in the subpericardial connective and adipose tissue. In the muscle the medullated nerve fibres lack ganglia cells. The sheath of the nerve fibres, on or between which the cells and ganglia lie, is prolonged over the surface of the latter. Isolated cells show the following structure: A central protoplasmic cell body with vesicular nucleus and nucleoli, mostly excentric, invested by a capsule of nucleated connective tissue. From the cell proceeds a process which cannot usually be traced. Certain ganglia cells give rise to medullated fibres; bi-nucleated cells are often met with, and most of the cells contain pigment. In every ganglion occur twisted and looped fibres, which unite to form the nerve trunk leaving the ganglion, and break up into smaller trunks. Some fibres do not enter the ganglia, but join the others in their course. No positive conclusions could be arrived at as to the nerve endings in the muscle cells.

LEAD-POISONING AND HOME-MADE WINES.

THE *Wiltshire Telegraph* of October 23rd contains the report of a very important and instructive investigation by Dr. Campbell, Medical Officer of Health for Calne, into the cause of a certain outbreak of cases of lead-poisoning in the months of August, September, and October, which had puzzled him for a long time. The cases occurred chiefly, almost entirely, in men, and coincided roughly with harvest work. Examinations of drinking-water, beer, tea, coffee, bread, and various cooking utensils gave no light. The occurrence of seven acute cases about three weeks since, two fatal, led to the discovery of the real source of mischief. The wife of one of the men explained that her husband had drunk some home-made rhubarb wine. She was sure "it could not contain poison of any sort, as she was very careful in selecting and cleaning her rhubarb, and as for the

sugar and barm, they were all right. *Besides, the vessel was a beautifully clean glazed earthenware pan*, in which she steeped it for a fortnight or three weeks to ferment." Here was the source of the poison, as Dr. Campbell says: "As is well known, this glaze contains 60 per cent. of white or red lead, and during the process of fermentation the acids of the fruit used, with the acetic acid or vinegar generated, act on the glaze and dissolve the lead, forming acetate or sugar of lead, a powerful irritant poison even in small quantities." Not only rhubarb, but red and black currants, sloes, and damsons are so used, and some thrifty wives have been able to supply their husbands with gallons for use in the harvest time. Dr. Campbell says that the same vessels are used for making bread, and that in one case there were slight indications of lead-poisoning in a teetotaler apparently from eating the bread. He recommends the wine to be made in wooden vessels. Dr. Campbell's careful report should lead to much more care in the use of glazed vessels, in culinary operations, as many contain lead in easily soluble forms. His work is an admirable illustration of the uses of an officer of health.

CHAIR OF MATERIA MEDICA IN ABERDEEN UNIVERSITY.

AMONGST the candidates for the chair of Materia Medica in the University of Aberdeen is Dr. Alexander Napier, one of the editors of the *Glasgow Medical Journal*, and assistant to the chair of Materia Medica in the Glasgow University, Dr. Gibson of Edinburgh, and Dr. Macgregor Robertson of Glasgow, are also spoken of as probable applicants. The patronage of the chair is in the hands of the Secretary of State for Scotland.

CAUSATION OF PNEUMONIA.

MR. HENRY BAKER of Lansing, Mich., contributes a note to *Science* (Aug. 27th) in confutation of Dr. Siebert's conclusion that pneumonia most prevails in such atmospheric conditions as are marked by a low temperature and excessive humidity. Mr. Baker points out that the absolute humidity of the air varies with the temperature, and that when the air is coldest it is then absolutely driest. He showed at a late meeting of the American Climatological Association that pneumonia, in any given place, wherever studied, is quantitatively proportional to the coldness and dryness of the atmosphere. He rather ingeniously accounts for this by such a condition requiring a greater exhalation of watery vapour, whereby the non-volatile chloride of sodium is left behind in the air cells, its presence favouring the osmosis of fibrine elements from the blood into the pulmonary parenchyma. Thus would be explained the known excess of this salt in the pneumonic lung, and its diminution in or disappearance from the urine.

SPONTANEOUS SHEDDING OF NAILS IN HYSTERIA.

DR. T. FALCONE of Naples records a case of hysteria, prolonged and aggravated, in the course of which there was spontaneous shedding of the finger- and toe-nails (*Deutsch. Med. Woch.*, Oct. 14th). The patient was fifty years of age and since 1870 had, after a mental shock, been subject to hemicrania and other nerve symptoms, including paraplegia, hyperæsthesia, globus, &c. She recovered, but after remaining well for six years the symptoms returned on the occasion of her first visit to the grave of her son, whose death had in the first instance been the exciting cause of her attacks. The affection of the nails was preceded by tingling in the fingers and toes, especially the thumbs and great toes, followed by suppuration in the bed of the nail. It was noted that on the right thumb the new nail was formed directly from the bed of the nail by proliferation of epithelium, which assumed a horny character; but on all the other affected fingers and toes the repair took place in the usual way—viz., by growth from the matrix. The condition altogether was regarded as a dystrophic one due to disordered nerve function.

OPENING OF THE SESSION AT BRUSSELS.

THE public opening of the winter session in the University of Brussels seems to have been attended with more disturbance on the part of the students than is usually the case with this ceremony, the differences amongst the professorial staff during the past academical year having given occasion for the display of some feeling. One of the orators gave considerable offence by omitting all reference to three professors—MM. de Roubaix, Thiry, and Crocq, who have been superseded. M. Crocq's entrance after the speech referred to was a signal for prolonged cheering. The students also manifested their approbation whenever the name of the outgoing rector, M. Rousseau, was mentioned, and subsequently met together to arrange a "manifestation" in his honour.

THE TERM "RHEUMATISM."

IN the course of a paper on Rheumatism, read at the recent Berlin Congress of Naturalists and Physicians, Professor Senator, who adduced evidence to prove that rheumatism is a specific disease, made some remarks upon the popular acceptation of exposure to cold being a cause of disease. (*Deutsch. Med. Woch.*, No. 41.) He said that undoubtedly many painful affections of the locomotor system, many neuralgiæ and paralyses—e.g., facial,—arise from sudden exposure to cold, especially if the surface be heated and bathed in sweat. But the term "cold" should only be applied to cases where the history of such exposure was quite clear, and the diseases produced thereby should be termed "refrigerant" rather than "rheumatic." The use of the words "rheumatism" and "rheumatic" should then be reserved for such cases of disease as are not due to mere cold, but to a special kind of miasmatic infection, like that which excites acute rheumatism—the prototype of rheumatic disease,—and are amenable to specific treatment. Although this may be merely a matter of words, yet, as he truly remarked, correct nomenclature implies correct conceptions of the conditions named.

UNUSUAL COINCIDENCE.

ON the 18th of this month a man and his wife were admitted into St. Thomas's Hospital suffering from acute pneumonia of respectively three and four days' duration. Each was aged thirty-two years. The disease ran an acute course, being little influenced by treatment, and they died at the end of four days within a few hours of each other. At the post-mortem examinations, which were made on the same day, acute inflammation of the right lung was found in each; this had attacked chiefly the base in the case of the man, and the apex in the woman. It would appear that they had left their house, and moved into lodgings only two or three days before the commencement of the disease, on account of the bad smells, making it probable that the disease was of septic origin.

MICROBES OF THE SOIL.

THE value of the action of microbes in the soil would not be questioned by anyone who had given the matter sufficient thought. But to establish a conclusion by means of experiment always commends itself to the scientific mind. M. Laurent has made a series of comparative experiments in order to ascertain the influence of the microbes on vegetable life. Seeds of buckwheat were sown in four different kinds of

mould. In the first flowerpot natural mould was employed, in the second the same earth sterilised and then inoculated with bacteria of the soil, in the third simply sterilised mould, and in the fourth sterilised mould with the addition of chemical manure. Precautions were taken to prevent contamination of the four receptacles (*Journal de Pharmacie et de Chemie*, No. 7). The production of wheat in each of the pots respectively was in the proportion of 94, 96, 23, 66. In all the experiments the third series was inferior to the others. The value of microbes in soil rich in organic detritus seems thereby to be proved.

THE MEDICAL COUNCIL.

THE Medical Council is summoned to meet on Nov. 16th, in its present imperfect form. The direct representatives will not come into office before January, 1887, though the election may be expected to take place about the end of November.

CHOLERA ON BOARD A BRITISH TROOPSHIP.

ON the 24th instant telegraphic information was received from the island of Perim, at the mouth of the Red Sea, to the effect that four deaths from cholera had occurred on board the troopship *Euphrates* since that vessel left Bombay. The *Euphrates* was reported to reach Suez on the 30th, and information as to the action which may have been taken there with regard to the ship and those on board has not yet arrived.

BOWMAN LECTURE.

THE Executive Council of the Ophthalmological Society are to be congratulated on their enterprise in having secured the services and talents of Professor Zehender of Rostock, who will deliver the Bowman Lecture this year at the rooms of the Medical Society, Chandos-street, on Friday, Nov. 12th, at 9 P.M.

NEW ENTRIES.

The following returns arrived too late for publication in our last issue:—

Cambridge University.—116 freshmen, a number which will be increased when the lists of the previous examination are published.

Bristol Medical School.—First year's students, 18; occasional, 1.

FOREIGN UNIVERSITY INTELLIGENCE.

THE following *agrégés* (assistant professors) have been appointed to lecture on their respective subjects in the different French Faculties of Medicine:—*Bordeaux:* M. Moussous, Medical Pathology. M. Pousson, Surgery. M. Ferré, Anatomy and Physiology. M. Nabias, Natural History. *Lille:* MM. Lemoine and Chuffard, Medical Pathology. M. de Lapersonne, Surgery. M. Assaky, Anatomy and Physiology, M. Barrois, Natural History. MM. Lambling and Morelle, Chemistry. M. Thibault, Pharmacy. *Lyons:* M. Weil, Medical Pathology. MM. Rodet and Jaboulay, Anatomy and Physiology. M. Hugonneng, Chemistry. M. Didelot, Physics. M. Florence, Pharmacy. *Montpellier:* MM. Forgue and Truc, Surgery. M. Gerband, Midwifery. M. Gilis, Anatomy and Physiology. M. Malosse, Physics. *Nancy:* M. Vautrian, Surgery. MM. René and Nicholas, Anatomy and Physiology. M. Guérin, Chemistry. *Paris:* M. Quenu, Anatomy and Physiology. M. Villejean, Chemistry.

Brussels.—The death is announced, at the age of eighty-four, of Dr. E. Lequime, who was for many years Honorary Professor of Clinical Medicine in the University. He edited the *Archives Médicales Belges*, and afterwards *La Belgique Médicale*, and wrote a good deal especially on cholera. He was officer of the Order of Leopold, and, notwithstanding his advanced age, attended regularly the meetings of the Academy until quite recently.

Dorpat.—Dr. Julius Kennel of Wurzburg has been appointed Professor of Zoology.

Valencia.—Dr. Don Enrique Ferrer y Viñerta, Rector of the University and Professor in the Medical Faculty, has received the Grand Cross of Isabel the Catholic.

The editorship of the *Wiener Medicinische Presse*, which is being given up by Professor Schnitzler, will, at the commencement of the new year, be taken over by Dr. Anton Bum.

A CIRCULAR has been issued by the Local Government Board to all urban and rural sanitary authorities in the kingdom, drawing attention to the provisions of the Contagious Diseases (Animals) Act, 1886, which transfers to that Board the powers hitherto exercised by the Privy Council for making regulations concerning cowkeepers, dairymen, and purveyors of milk, and transfers to the sanitary authorities the duties of making regulations under and enforcing the provisions of the Dairies, Cowsheds, and Milkshops Order of 1885 issued by the Privy Council. The circular reminds the authorities that they are required to register all persons who may carry on the trade of cowkeepers, dairymen, or purveyors of milk, and to look after the lighting, ventilation, cleansing, drainage, and water-supply of dairies.

THE St. Giles's District Board of Works have issued notices to the tenants of some twenty-eight houses in a street off Shaftesbury-avenue, the new thoroughfare recently formed by the Metropolitan Board of Works, requiring them, within seven days from the 23rd inst., to yield up possession of the premises for the purpose of closing the same. This action has been taken by the Board in consequence of the owner of the property, Sir T. H. Brinckman, Bart., having failed to comply with an order issued by the Board to execute certain sanitary works and to make structural alterations in the whole of the premises, to render them fit for human habitation. The order involves the removal of about 500 persons, but the clerk of the Board explains that as soon as the work ordered has been completed the houses may be reoccupied.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of September, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies still maintained the character of the July and August samples, the proportion of organic matter present being again, for river water, exceptionally small. The water drawn from the Lea and distributed by the New River and East London Companies contained even less organic matter than the Thames waters. All the waters were clear and bright on delivery.

PROFESSOR BROWN-SEQUARD brings forward a number of pathological and experimental facts to show that it is an error to suppose that cadaveric rigidity is due to a coagulation of the albuminous principle of muscle. The chief, and sometimes the only, cause of rigor mortis resides in a true muscular contracture, which is a vital phenomenon, although occurring post mortem.

AN Act has received the Royal Assent by which a company is incorporated to take over the existing partial system of waterworks at Sidmouth, and by the construction of further works to give the town and neighbourhood a proper and

IT will be of interest to those engaged in chemical research to learn that the French Senate has adopted a *projet de loi* to institute a prize for the discovery of simple and practical means of determining the presence and quantity in spirituous liquors of other substances than ethylic alcohol, and the proposition now lies with the Chamber of Deputies. The subject of wine adulteration is also under discussion at the Academy of Medicine, which has been officially requested to advise upon the question by the Government.

ON the 22nd inst., Dr. Alexander Dyce-Davidson, Professor of Materia Medica in Aberdeen University, died suddenly in his class-room. The bursting of a bloodvessel in the head was the cause of death. The deceased was a native of Aberdeen, and was forty-one years of age. He was appointed Professor of Materia Medica in 1878.

DR. THOMAS SLEEMAN REED, of Pool, near Camborne, died on the 22nd inst., after a short illness, the immediate cause of death being blood-poisoning, contracted during the performance of an operation on the foot of a miner. The deceased was well known and highly respected throughout the district in which he resided.

THE *London Gazette* of the 22nd inst. contained an announcement that the date of the general order of the Local Government Board prohibiting the importation of rags from Italy, in consequence of the prevalence of cholera in several parts of that country, has been extended from the 1st prox. to April 1st, 1887.

DR. STIRLING, Professor of Physiology in Owens College, commenced on the 26th inst. to deliver a course of eight lectures on the Physiology of Food, Digestion, and Respiration in connexion with the Combe Trust. This is the first time that the Combe Lectures have been delivered in England.

ARGUMENTS signed by Messrs. P. F. Coghlan, J. J. Jackman, and J. B. N. Cane, in favour of increasing the fees of union medical officers for inspecting the buildings to be erected under the Labourers' Cottages Act, have recently appeared in the *Waterford Times*.

A GERMAN Anatomical Society has been founded, with Prof. Kölliker as President and Prof. Bardeleben as Secretary.

THE FELLOWS, MEMBERS, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

HISTORY AND INFERENCE.

FOR many years before his death Mr. J. F. South was known to be engaged in collecting materials preparatory to writing a history of the College of Surgeons, but he did not live even to arrange the mass of facts and papers which he had gathered together. His manuscripts, having been sent to the College of Surgeons, have been edited by Mr. D'Arcy Power, and were published a few months ago under the title of "Memorials of the Craft of Surgery in England," with an introduction by Sir James Paget. It is not our intention at present to criticise either Mr. South's collection or Mr. Power's editing, or to consider to what extent these "Memorials" contribute to the history of surgery in England. What we wish now to do is to make use of some of the data scattered about the pages of these "Memorials," to elucidate some of the questions that have lately been exercising the minds of the Council, the Fellows, and the Members, and which are likely to come prominently to the front again at the general meeting of Fellows and Members of the College, to be held next Thursday. In another column we publish some resolutions which it is intended to move at this meeting, and it will be seen that they refer to the corporate rights of the Members, the academic status of the Fellows, and to the claim of the Fellows and Members to sanction any alterations that may be made in the constitution and relations of the College or in any of its bye-laws.

In order to understand the anomalous constitution of the College as it now exists, it would be necessary to trace the history of the rise and progress of the various companies and corporations which preceded the College, and from which the College is descended. Mr. South's "Memorials" in their present form afford only casual and incidental aid in such a task. But fragmentary as they are, they do furnish sufficient evidence that the exclusive exercise of legislative powers by the Council is a flagrant violation of the fundamental principle of *corporation*.

Sir James Paget, in his brief and apologetic introduction, remarks "it is an error to suppose that English surgeons are, in any fair sense, the descendants of barbers." Happily this is strictly true. But to allege that "the surgeons from whom our College can trace an uninterrupted descent were not barbers" is not, in any fair sense, either historically true or logically consistent. The constitution of the College, as laid down in the Charter of the year 1800, is almost identical with that of the old Corporation of Surgeons, and this was framed on the same lines as the Combined Company of Barbers and Surgeons, which in its turn was merely an extension of the original Company of Barbers. Their principles of government are similar, their later policy and prejudices identical. It betrays a strange misapprehension of the nature and history of these and kindred institutions when a writer usually so accurate as Sir James Paget can suggest that the events recorded in these "Memorials" should be studied "as the history of a *development*"; whereas, on the contrary, they afford a most striking and typical illustration of what Brentano, in his "History and Development of Gilds," designates the *degeneration* of Craft Gilds. A brief survey of the history of these Gilds, of which the Barbers' Company, the Corporation of Surgeons, and the College of Surgeons are ordinary examples, will make this clear.

In the eleventh century the handicraftsmen of Europe were divided into two classes, the bondmen and the freemen. The latter belonged originally to the body of full citizens, and as members of the full Citizens' Gilds, enjoyed under the protection of their Gild immunity from external interference, while the former continued for some time subject to the control of the town or other authority in all matters relating to their trade. Even when the free handicraftsmen were expelled from the full Citizens' Gilds they maintained their independence, and exercised their right to freely elect their own warden. On the other hand, the Craft Gilds, made up of the whilom bondsmen, when obtaining their privileges, were frequently compelled to pay certain imposts in return for their greater independence, and had to consent to have their warden appointed by external authority. These and other considerations make it almost certain that the fraternity of Barbers consisted originally of bondmen who had obtained a smattering of medical knowledge and acquired some dexterity in performing minor surgical operations. Persons of this class swarmed in Europe from the second to the eighteenth century. Oribasius, writing in the fourth century, deplores not less the scarcity of properly educated medical men than the superabundance of pretenders of the medical art, who, though knowing only how to bleed, apply cupping glasses, make scarifications and other *servile* offices (*καὶ τὰ ἄλλα τῆς ὑπηρετικῆς ἐμπειρίας*), did not hesitate to arrogate to themselves the whole of medical practice, to the great detriment or actual destruction of their patients. Of such were the barber-surgeons of the fourteenth and succeeding centuries.

The idea implied in the foundation of all Gilds is that of a brotherhood for mutual help and support. As Wilda aptly remarks, the Gilds were "imitators of the family." The Craft Gilds were, however, more especially interested in the maintenance of the rights, privileges, and customs of the Craft. The essence of these Gilds was its general meetings, at which all the Gildmen met. The president or warden, who was always elected by the whole Gild, summoned the meetings and presided at them, and with the consent of those present enacted ordinances for the regulation of the Craft, and had to see that those ordinances were carried out.

But when in the course of time the Craft Gilds obtained complete independence and authority in all matters relating to the Craft, there soon set in the *degeneration* of Gilds. The fees for membership were raised to an extortionate amount, and the members of the executive body began to entrench themselves behind restrictions, and thus gradually succeeded in transferring the government of the Gilds into the hands of a few of the richer or more influential families. Towards the end of the sixteenth century, instead of the general meetings of all the Gildmen, a "Court of Assistants" sprang up, who governed the Gild and enacted its ordinances, and in the seventeenth century the transfer of the elective franchise from the "Community" to the Courts of Assistants was generally recognised in the Charters. The Courts of Assistants were henceforth elected for life, and as individual members died the "Court" filled up the vacancies without reference to the opinion or wishes of the Community. An oath was also introduced, in which all the members swore to obey the master and wardens and *their* ordinances. This transference of authority from the assembled members of the Gild to the Court of Assistants was, however, not always effected without resistance. It appears, from a pamphlet of the year 1649, mentioned by Brentano, on the "Constitution of the Clothworkers' Company," that a part of the Gild associates, relying on the old Charters of the Gild, claimed for the whole body of the Gild members both the right of electing their wardens and of framing ordinances. In answer to this contention, "this pamphlet endeavours to prove," says Brentano, "with the most arbitrary misrepresentation of the sense and the words, that the word 'commonalty' in the old Charters meant, not the collective body of Gild members, but only the master, warden, and assistants." This was, be it remembered, nearly 250 years ago; but the Council of the Royal College of Surgeons of England, in the year of grace one thousand eight hundred and eighty-six, is not ashamed to resort to a similar subterfuge when eighteen thousand members of the Corporation claim the right to elect the president, to participate in the legislative acts of the College, as well as to supervise and sanction any alterations that may be made in the constitution or relations of the College, or in any of its bye-laws.

This common tendency and this culmination of Craft Gilds may be discovered in the history of the College of Surgeons, as described in Mr. South's "Memorials." In 1308, a warden was elected by the barbers and presented to the Lord Mayor; in 1375, two wardens were "chosen by common assent" of the craft; in 1415, two wardens were chosen "by a majority of the barbers practising surgery"; in 1423, the members of the conjoint Colleges of Physicians and Surgeons were of themselves to choose in prescribed form surveyors, &c.; in 1435, the members of the Guild of Surgeons were instructed to yearly come together on the day of St. Cosmo and Damien to choose four masters for the year "as oold custum was"; in 1461, the charter of Edward IV. provided that the Fellowship of Barbers were to elect two masters, and that whenever need be they were to make honest and lawful assemblies of themselves, and "also ordeyne and make Lawes and Ordenannces"; in 1493, the members of the Combined Fellowship of Barbers and Surgeons were to choose of themselves two wardens. These powers and privileges were confirmed in 1526 by Henry VIII.; but the process of "degeneration" had already begun. The master and wardens not only conducted the ordinary business of the Company, but began to speak of the statutes, ordinances and oaths as those, not of the Company, but of the "master and wardens and their predecessors." Henceforth the degeneration spread rapidly. In 1604, by an Act of Parliament, the Court of Assistants were to be elected for life, and the master was to be chosen from among the assistants. The ordinary members of the company were more or less excluded from sharing in the management of the company. The Act of 1745, by which the Surgeons' Company—the immediate progenitor of the present College of Surgeons—was instituted, prescribed that the assistants were to be elected for life, the master and wardens were to be elected from the assistants, and "the power of making bye-laws and elections was vested in the master, wardens, examiners, and assistants." Meetings of members were rarely summoned, the last general meeting being, we believe, held in the year 1786.

The Charter of the year 1800, by which the College of Surgeons was founded, secured to the Court of Assistants the sole exercise of [redacted] and legislative powers of the College. Great pains were taken to exclude Members of the College from exercising any control over either of these functions. Any loophole that may have been left through the inadvertence of those who inspired the Charter was stopped—*O tempora! O mores!*—by a bye-law framed in the year 1831, to prevent Members from meeting in the College. By a strange irony of fate, it is under the provisions of this bye-law that the meeting next week will take place. This is history; the inference is obvious.

VICTORIA HOSPITAL, BURNLEY, LANCASHIRE.

A CORRESPONDENT has favoured us with the following description of this hospital, which was opened by His Royal Highness Prince Albert Victor a few days ago, and which presents several points of novelty and interest in hospital construction.

The building consists of a central administrative block of three floors, with kitchen and laundry (detached one-storey buildings) at the back. At either side there is a one-storey ward block, connected by a cross-ventilated corridor, behind one of which is the out-patients' department, with access from the back of the site. Each ward block contains two small isolation wards, with a ward scullery and sister's room, and the ward itself, which is for twenty beds, and is circular in form, of 60 ft. internal diameter. The roof is flat, formed of concrete on iron girders, covered with rock asphalte, and is utilised for a convalescent day-room and smoking-room, glazed all round, and surrounded by a promenade 12 ft. wide. Access to the roof is obtained by a spiral staircase, occupying the centre of the ward, and enclosing an annular ventilating flue, which again surrounds a central smoke flue. In this ward are carried out very completely the suggestions of Professor John Marshall, who in this country first advocated this form of ward in a pamphlet "On a Circular System of Hospital Wards" (Smith, Elder, & Co.). The advantages this shape offers are: the absence of corners—there are absolutely none in this ward, as the walls meet both floor and ceiling with a round curve in place of the usual right angle; the greater relative amount of floor space that a given length of wall space in the form of a circle can enclose; the larger amount of light, especially of sunlight, received; the facilities for working; and the greater comfort of the patients, whose fellow-sufferers on the opposite of the ward are so far removed. More equable lighting and heating are readily secured, in this form of ward, while for ventilation the facilities are greater than in buildings of any other shape. The attention of Dr. McKenna of Melbourne, who more than thirty years ago first advocated this system, was drawn to it by his experience of the better results obtained in the treatment of wounded soldiers in the Spanish-American colonies when placed in circular buildings than when in those of the ordinary rectangular form. The floors of the ward are of polished oak; the walls of glazed bricks, pointed with cement; the windows are of British plate glass, made in three sections, the top ones opening inwards on hinges. The ceiling is made of Robinson's cement—a new variety, which can be applied on laths, and it is hoped that in this way a surface physically as smooth, hard, and impermeable as those of the floor and walls has been secured for the ceiling also, and that thus an important advance has been made on the ordinary plaster, which hitherto has been the only material that could be used for this purpose. The ward is lighted by three Wenham lights. The gas is burned in a closed glass chamber, practically outside the ward, and the products of combustion, warming the fresh air on their way upwards, are conducted into the ventilating shaft. The air consumed by the gas is drawn from the ceiling level, warmed on its way down the pipe, thus securing complete combustion and a brilliant white light, while assistance is given to the ventilation of the ward, and all noxious products are removed. For heating the ward three of Mr. Saxon Snell's thermhydric stoves are placed towards the middle of the ward, each connected with the single central smoke flue; but steam, which is used in the laundry and kitchen, and generally for warming water throughout the building, is also to be used for warming the wards. Two rows of graded pipes one inch and a half in diameter are placed along the bottom of the outer wall of the ward; while five such rows surround the central block, except at

the entrance to the staircase. They are worked from the subway, so that any one, or all, may be used as required; and the arrangements are such that they can not only be worked, but even started, without any of the noise hitherto always associated with this means of heating. This was done during the visit of the Prince, steam being introduced into the perfectly cold pipe while he was in the ward without any noise whatever. As the whole of the outside wall can thus be uniformly heated without any disturbance to the patients, it is considered that in this point also a very great advance has been made. In the matter of ventilation, besides the advantages offered by the form of the ward, and the eighteen large windows, each with deep-bottom frame, so as to admit air between the sashes at the middle of the window, Ellison's conical ventilators have been introduced below the windows between the beds; while over each bed, eight feet from the floor, a Sheringham valve has been placed. Around the central block at the ceiling level exit openings for the air have been inserted, the flues from which ascend in the inner wall of the day-room, or sun-room, above, and thence proceed to the upper part of the central ventilating flues. By these the warm air in winter will readily make its way out. The arrangements for ventilation in summer are very perfect. At the floor level eight horizontal flues are provided, which run inwards below the stair to the bottom of the ventilating chamber, which surrounds the central smoke flue. This is annular in form and over thirty feet in height, and contains a series of four coils of steam pipe, each of different size, all worked separately from the subway. By these means fourteen different amounts of heating surface can be obtained in the flue, and it is hoped that even on the warmest summer day the column of air in the ventilating chamber, thirty feet in height, may be warmed to such an extent that it will ascend and draw the air through the ward at a rate sufficient to keep the air pure and the ward well ventilated. In Dr. John S. Billings' work on the Principles of Ventilation and Heating (New York *Sanitary Engineer*), attention is drawn to Professor Troubridge's investigations on the determination of heating surfaces required in ventilating flues, and descriptions are given of the arrangements in the Columbia College and the Johns Hopkins hospital, but in neither of these does there seem to be the necessary power of varying the amount of heating surface according to the external temperature, which is provided in the ventilating flues of the wards of the Victoria Hospital.

HONG KONG.

THE report of the Colonial Surgeon at Hong Kong for 1885 shows it to have been a very unfavourable year for the foreign residents, 3040 in number. The death-rate among them was higher than in any of the nine preceding years, and amounted to 32·56 per 1000 living; among the white troops it was 15·27, and for the rest of the European and American residents, 42·57. We are, however, without any information as to the composition of the latter in regard to age. The high rate of mortality among the troops, greatly above the average of the preceding five years, was due to an outbreak of cholera, which caused half of the deaths. The source of the disease could not be traced. No cases occurred among the police or in the gaol, and only nine were received into the Government Civil Hospital, of which six proved fatal, three being destitute European seamen, and three Chinese. The admissions into hospital of the white troops were 886 per 1000 of the strength, considerably under the average of the preceding five years; those of the black troops were 1173, and the deaths 20·46 per 1000 in an average strength of 173 men. In the police force the death-rate of Europeans was 26·0, of Indians 5·5, and of Chinese 13·2 per 1000; but the numbers employed are too small to justify any positive deductions from these results. The daily average number of prisoners in the Victoria gaol was 530, the admissions into hospital were 255, and 42 were treated in their cells, making a total of 297 cases, of which two died; these numbers give a ratio of 560 cases, and 3·77 deaths per 1000, a result which compares very favourably with the gaol statistics of India. The Tung Wa Hospital, "which is entirely managed by Chinese directors and doctors," continues to furnish an enormous death-rate in proportion to the cases. In 1885 the number of patients treated in it was 1967, and the deaths amounted to 1006. But 283 were moribund on admission; if these be deducted, there still remain 723 deaths in 1684 cases, or 42·9 per cent. "The chief reason for the great mortality in this hospital is that most of the patients when admitted are hopeless cases, the Chinese having a great antipathy to going into hospital at all except in the last extremity, or in case of utter destitution." Mr. Ayres, the colonial surgeon, calls attention to the lamentably defective state of sanitation in Victoria, the subsoil of which "is steadily being poisoned by sewage," and to the difficulty of getting even European house-owners to undertake the necessary sanitary measures of improvement. With regard to quarantine, he believes it to be perfectly useless in excluding cholera, even if it could be properly enforced. "What we have got to do," he says, "is to look at home, and not prepare a hotbed for the reception of disease, as a gardener does for mushrooms." Malarial diseases, fevers and bowel complaints, are the most prevalent, and are followed in many instances by severe anæmia and serious deterioration of health. It is evident there is much required to be done to put the town in a decent sanitary condition. Till that is accomplished, "it is reasonable to expect that the colony will become every year more and more liable to an epidemic of cholera. . . . . A more plentiful supply of water may do something to retard the evil day, but nothing short of a general conflagration in China town is likely to avert it." The colonial medical staff is still kept down at starvation point, and is obviously insufficient for the duties required of it, especially in the event (by no means improbable) of even one of its members falling sick. We trust that the question of an increase to its numbers may receive the favourable consideration of the Colonial Office.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Scarlet Fever at Atherton, by Dr. PARSONS.—The average annual death-rate from scarlet fever between 1876 and 1885 at Atherton, in Lancashire, amounted to 1·40 per 1000 of the population, whereas it was only 0·55 for England and Wales. The total mortality and the infantile mortality are also excessive; and measles as well as scarlet fever tend to recur in an epidemic form every five years. The scarlatina spread immediately under consideration was largely due to the free intercourse between households infected and those as yet uninfected, the parents looking upon scarlet fever as a thing that everyone ought to have, and therefore the sooner it was over the better. The wearing of infected clothing at the mills and participation in large funerals also had a share in producing spread of the disease. The arrangement of the houses, opening as numbers of them do on to common back spaces, and the use of common privies, also tended to the extension of the infection; and badly kept, ill-paved yards, together with inadequate ventilation of houses, were found amongst the insanitary conditions which doubtless tended to increase the severity of the disease. The attempt, during a previous epidemic, to secure isolation in a cottage hired for the purpose failed, although admission was free; but this failure was, perhaps, in part due to the fact that the mothers of sick children were not admitted. It has very generally been found that the admission of mothers is not a serious inconvenience, since they are, as a rule, ready to go out and leave their children directly they find that the isolation arrangements are comfortable. In the absence of isolation, disinfection, though assiduously carried out, proved of little value, and, as Dr. Parsons observes, the reduction of scarlet fever in districts like Atherton must be sought mainly in the instruction and enlightenment of the people themselves. Although there has been some sanitary progress in Atherton during the past ten years, yet numerous defects still remain, and faults of house-drains, together with the mischievous form of midden-privy which has long been such a common source of nuisance in Lancashire, are among the most prominent that call for immediate

action on the part of the sanitary authority. In 1885 there were forty-one deaths from measles and fifty from scarlet fever in a population of 13,500. This is an altogether unnecessary waste of human life.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5947 births and 3371 deaths were registered during the week ending Oct. 23rd. The annual death-rate in these towns, which had declined in the preceding six weeks from 22·6 to 18·9, was last week 19·3. During the first three weeks of the current quarter the death-rate in these towns averaged 19·2 per 1000, and was 1·0 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 12·7 in Nottingham, 13·9 in Brighton, 14·1 in Huddersfield, and 14·8 in Birkenhead. The rates in the other towns ranged upwards to 24·5 in Manchester, 25·3 in Halifax, 27·4 in Wolverhampton, and 33·5 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding six weeks from 1202 to 540, further fell last week to 438; they included 183 from diarrhœa, 83 from scarlet fever, 56 from measles, 49 from "fever" (principally enteric), 35 from whooping-cough, 32 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Newcastle-upon-Tyne, Cardiff, and Portsmouth; and the highest in Preston, Wolverhampton, and Halifax. Diarrhœa caused the highest death-rates in Norwich, Bolton, Preston, and Wolverhampton; scarlet fever in Huddersfield, Liverpool, Salford, and Bristol; measles in Wolverhampton and Halifax; "fever" in Sunderland and Plymouth; and whooping-cough in Sunderland and Oldham. The 34 deaths from diphtheria in the twenty-eight towns included 25 in London, 2 in Liverpool, and 2 in Sheffield. Small-pox caused no death in London and its outer ring, or in the twenty-seven large provincial towns. Only 3 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 229 and 223 in the preceding two weeks, rose last week to 290, but were 46 below the corrected average. The causes of 69, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, Newcastle-upon-Tyne, Nottingham, and in three other smaller towns. The largest proportion of uncertified deaths was registered in Sunderland, Birkenhead, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 19·5 per 1000 in the preceding two weeks, further declined to 18·2 in the week ending Oct. 23rd; this rate was 1·1 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 9·7 and 11·5 in Greenock and Perth, to 19·4 and 21·6 in Aberdeen and Glasgow. The 450 deaths in the eight towns last week showed a further decline of 32 from the numbers in the previous two weeks, and included 25 which were referred to diarrhœa, 17 to scarlet fever, 17 to whooping-cough, 6 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 2 to measles, and not one to small-pox; in all, 72 deaths resulted from these principal zymotic diseases, against 63, 82, and 88 in the previous three weeks. These 72 deaths were equal to an annual rate of 2·9 per 1000, which was 0·4 above the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 22 and 46 in the previous two weeks, declined again last week to 25, of which 11 occurred in Glasgow, 4 in Edinburgh, and 4 in Dundee. The fatal cases of scarlet fever, which had been 21 and 12 in the previous two weeks, rose again last week to 17, of which 9 occurred in Glasgow, 6 in Dundee, and 2 in Edinburgh. The 17 deaths from whooping-cough, on the other hand, showed a further decline from the numbers in the two previous weeks; 12 occurred in Glasgow. The 6 deaths referred to "fever" corresponded with the number in each of the preceding two weeks, and included 3 in Glasgow and 2 in Edinburgh. Three of the 5 deaths from diphtheria were returned in Edinburgh, and both the fatal cases of measles in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the previous four weeks from 65 to 98, declined last week to 79, and were 4 below the number in the corresponding week of last year. The causes of 53, or nearly 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 23·1 and 22·5 per 1000 in the preceding two weeks, further declined to 20·5 in the week ending Oct. 23rd. During the first three weeks of the current quarter the death-rate in the city averaged 22·0; the mean rate during the same period was 17·0 in London and 17·7 in Edinburgh. The 139 deaths in Dublin last week showed a further decline of 13 from the number in the previous week, and included 10 which were referred to diarrhœa, 7 to scarlet fever, 5 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and not one either to small-pox, measles, or whooping-cough. Thus the deaths resulting from the principal zymotic diseases, which had declined in the preceding five weeks from 39 to 16, rose again last week to 23; they were equal to an annual rate of 3·4 per 1000, the rates from the same diseases last week being 1·9 in London and 2·7 in Edinburgh. The fatal cases of diarrhœa, which had decreased in the previous four weeks from 29 to 11, were 10 last week. The deaths referred to scarlet fever and "fever" exceeded the respective numbers returned in the previous week. Four inquest cases and 2 deaths from violence were registered; and 40, or nearly a third of the deaths, occurred in public institutions. The deaths both of infants and of elderly persons showed a decline from the numbers in the previous week. The causes of 16, or more than 11 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Randolph Webb has been placed upon temporary half-pay on account of ill-health; Brigade Surgeon John Davidge has been granted retired pay with the honorary rank of Deputy Surgeon-General. The undermentioned Surgeons-Major are granted retired pay, with the honorary rank of Brigade Surgeon:—John M. Fiddes, M.B.; William Morton Harman, M.B.; Surgeon-Major Joseph Fleming, M.D., from half-pay, to be Surgeon-Major, vice T. M. Kirkwood, deceased.

INDIA OFFICE.—The undermentioned Officers of the Staff Corps and Indian Military Forces have been permitted to retire from the Service:—Surgeon-General Michael Cudmore Furnell, of the Madras Medical Establishment, and Brigade Surgeon Charles Kelway Colston, of the Bombay Medical Establishment.

ARTILLERY VOLUNTEERS.—1st Invernes-shire: Murdo Mackenzie, Gent., to be Acting Surgeon.—6th Lancashire: Acting Surgeon Charles Joseph Trimble to be Captain.

ENGINEER VOLUNTEERS.—1st Cheshire: Andrew Stewart, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Fifeshire: Acting Surgeon H. Gordon, M.D., resigns his appointment.—2nd Volunteer Battalion, the York and Lancaster Regiment: Honorary Assistant-Surgeon R. Storrs resigns his appointment.

GREAT NORTHERN CENTRAL HOSPITAL.—The names of some influential gentlemen have been added to the committee of management of this institution and district committees formed in North London. These committees will soon issue an appeal for funds to defray the cost of the new buildings in the Holloway-road, which have just been commenced. We hope that this appeal will be successful, as it is deserving of full support from the many wealthy and charitable inhabitants of these districts, which will be so much benefited by the new hospital. On the 24th inst. a demonstration of the North London Amalgamated Temperance Associations was held in support of the building fund.

Correspondence.

"Audi alteram partem."

"REFORM AT THE COLLEGE OF SURGEONS."

To the Editor of THE LANCET.

SIR,—On Thursday, Nov. 4th, at 3 P.M., the Members of the Royal College of Surgeons of England will again, it is hoped, fill their theatre in Lincoln's-inn-fields with a body of men determined to attain fitting representation on the Council of that corporation. *L'union fait la force*, and no consideration of the personal inconvenience of individual Members should stand in the way of their assembling in their hundreds and ensuring for that meeting a success equally decisive with that of the meetings of last year. For two years and a half has this important question been under the bashful consideration of the rulers of the College, and at last they are asking for a definite plan to be formulated for their better information as to the views of the Members and Fellows. We are told "that it is not desirable to diminish the privileges of the Fellowship by depriving Fellows of the exclusive rights of electing to the Council, and of being eligible to become members thereof"; and yet, while the principle for which we contend is rejected, we are asked to offer up details. Surely by this time the Council of the College knows what the Members are seeking for! If it does not, after the 4th of November it will no longer be able to plead ignorance, for it will then have the main lines of the demand laid before it in a resolution, the terms of which he who runs may read. Let it then reply to this resolution either by an emphatic "No," or by granting the request embodied in the second resolution to be voted for that day—viz., to appoint a committee consisting of members of its own body, of deputies from the Associations of Fellows and of Members, and of independent Fellows and Members of the College, the said committee to draw up the detailed plan prayed for by the Council. Should the Council of the College refuse to grant these requests, which no impartial outsider could stigmatise as lacking in moderation, the Privy Council must be approached by a deputation of Members, including in its ranks, we hope, a contingent of Fellows, and bearing with it the petition, a copy of which your readers will find on p. 43 (advt.) of your issue of the 16th inst., signatures to which are coming in apace. In conclusion, we wish once more to draw the attention of Members of the College to that petition, earnestly begging their signature of the same, the present being a golden opportunity of their obtaining those rights which should never have been denied them.

We are, Sir, your obedient servants,

WARWICK C. STEELE,
W. ASHTON ELLIS, } Hon. Secs.

October, 1886.

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—Many things were necessarily omitted from the joint letter of Mr. Ker and myself in order to bring it within reasonable length, and I am much obliged to Mr. Hardy for now giving me an opportunity of supplying some of those omissions, and of correcting certain inaccuracies of statement and inference into which he and others have fallen. Going back to what took place at Brighton, there is another, and in my opinion a far juster, way of stating the facts than the one which he has adopted. It is as follows. The principle which I ventured to recommend as one likely to preserve us as a profession from much acrimonious personal discussion, namely, that of a primary recommendation of suitable candidates by a body of men, who, like the council of the British Medical Association, might reasonably be considered as above suspicion of unfairness—was discussed at two successive general meetings, one a very large and the other a very small meeting. At neither was any vote taken on my resolution, so that we are obliged to rely upon general impressions as to the sense entertained of it. My own idea is that the principle commended itself strongly to the very large meeting, and that if a vote could legally have been taken, it would have been adopted, with few if any dissentients. But to the very small meeting—the very, very small meeting, as it may be termed by comparison—it did not appear equally to commend itself; and recognising the inconsistency of allowing an extremely minute and numerically insignificant fraction of the previous day's meeting—which yet by peculiarity of the circumstances would be called the British Medical Association in general meeting assembled—possibly to arrive at a decision directly the reverse of its immensely larger predecessor, I withdrew the resolution, which therefore was never put at all. This having been done, the way was free to take any other course for testing professional feeling on what appeared to others, as well as myself, to be one of the gravest issues ever placed before us (for no one will doubt that our future must be greatly influenced by the character and ability of the representative that we shall return to the General Medical Council), and not being myself a member of the council of the British Medical Association, being untrammeled by office of any kind, and being, moreover, conscious of not having the remotest personal end to serve, I ventured to hope that anything that I might do would at least escape the risk of being supposed to spring from other than an honest desire to promote a good end, and that none of the numerous misrepresentations and imputations that are apt so to degrade the character of popular elections could be attached to it. The rest is soon told. A small conference was summoned by myself and two other gentlemen, who kindly acted with me, and at that conference it was decided to form a committee. My own part in the work must here be told, as the narrative will convince every unbiased mind of the absolutely free character of the committee. A few days only remaining before the day on which it was decided that a general meeting ought to be called, I procured 500 reply post-cards, and finding that the attempt to direct them myself, which I first made, would prevent their being issued at all, I placed them, together with a Medical Directory and a list of members of the British Medical Association, in the hands of a clerk, with no other directions than that they were to be widely distributed, so as to make them as useful as possible, and that they were to be sent by preference to gentlemen who were not members of the British Medical Association, and to those who, as far as could be judged, were in general practice. It was thought that by acting on such a principle the committee, though it would necessarily be a somewhat small one, would be likely fairly to reflect the general feeling of the profession. The result was not unsatisfactory. In two or three days 170 favourable replies were sent, and these, with the answers to circulars that had been previously issued by Mr. Ker, brought the number of the committee up to 350. The method for testing the opinion of these 350 gentlemen was the fairest that could possibly be adopted. It was simply that of asking them to choose three out of eleven gentlemen concerning whose qualifications not a word one way or the other had been said to them. Their judgment was not even biased by what took place at the meeting, as only 10 per cent. (about the usual proportion, I believe) were able to attend. And it is their decision, expressed in a most remarkable and decisive way—for it is certainly very remarkable that such a committee should have arrived at so united an opinion,—that is put before the profession, and not, as Mr. Hardy states, the decision of the three in whose honour they reposed sufficient confidence to entrust them with the duty of counting their votes.

Whether the attempt thus simply and honestly made to gauge the feelings of the profession from the feelings of a small portion of it indiscriminately appealed to will be a successful one or not remains to be seen. From the many hundreds of favourable replies thus far sent in we are encouraged to think that it will, and that the three gentlemen so freely indicated as likely to be of service to the profession will not improbably command as large a measure of support as those who adopted the more usual plan of announcing themselves as candidates and forming their own committees. One circumstance should not be omitted, as it indicates clearly the absence of bias on the part of the committee: it is that one of the three gentlemen finally selected is not even a member of the British Medical Association.

I am, Sir, yours faithfully,

Liverpool, Oct. 25th, 1886. WILLIAM CARTER.

To the Editor of THE LANCET.

SIR,—Dr. Stokes, the chairman of my committee, has received a note from a gentleman friendly to my candidature, but stating that, as "he believes me to be absolutely safe," he will use his vote in favour of a personal

friend, who he thinks has done good service to medical reform. Will you allow me to point out that if my friends, who are numerous and kind beyond all my desert, act on this view, I shall find myself at the wrong end of the poll. Many fair chances of election have been dashed by this sort of feeling. Allow me, therefore, to ask earnestly for one vote of every member of the profession who thinks that, as a general practitioner, and one having somewhat special knowledge of the working of the Medical Council, I can be of use in it.

As I am writing, let me take the opportunity of removing a doubt which a few of my friends seem to have, and one or two of my kind opponents seem to use a little hardly—viz., that I am not a *bond-fide* general practitioner. It is my pleasure, Sir, to be in active general practice, and, whatever the result of this election, it will be my greatest satisfaction to have had the wide support of my fellow practitioners.

I am, Sir, your obedient servant,

Highbury-place, October, 1886. JAMES GREY GLOVER.

To the Editor of THE LANCET.

SIR,—Having been a complete invalid for many months, I have had little inclination to take part in medical politics, and therefore the circulars emanating from the various candidates for representation in the Medical Council have been hardly looked at; but seeing that the election will shortly be upon us, I take the liberty of asking you to insert the subjoined in favour of two of the candidates who are before us, and to permit me to state the grounds on which I ask my Poor-law medical brethren and others to support them, and in order to prevent the supposition that I favour one more than the other I will take them alphabetically.

My first candidate is Sir B. Walter Foster of Birmingham. This gentleman for the too brief period that he was in Parliament secured by his great ability the ear of the House, and was an active supporter of direct representation. He is in the full vigour of life, active, eloquent, and industrious. He is sure of a seat in the next Parliament, and therefore he is one whom it is desirable in every way to secure as a friend, and being a Liberal is just that kind of representative that would make the dry bones that at present represent the various corporations stir a bit—perhaps reclothe them with flesh.

The second candidate for whom I solicit support is Dr. James G. Glover, of 25, Highbury-place, London. Dr. Glover, to my personal knowledge, has for many years been the advocate of reform in the Medical Council. He was an active member of the Committee on Medical Education which came into existence some years ago at the instance of Sir Andrew Clark, and whilst acting on that committee I had an opportunity of noting not only the very able work he did, but the clearness with which he advocated his views and the tenacity with which he adhered to them. There is, in addition, this fact in his favour—that he is not a person who can or will be swayed by those who represent the interests, and the interests only, of the corporations, to the detriment of the bulk of the medical public.

I am, Sir, yours obediently,

Montague-place, Russell-sq., Oct. 26th, 1886. JOSEPH ROGERS.

To the Editor of THE LANCET.

SIR,—At the present crisis, when for the first time the great body of the medical profession is about to choose its representatives on the General Medical Council, THE LANCET deserves the best thanks of all for the independent position which it has taken up in the matter.

The profession has too long been deprived of representation in the Council. Let us prove by the selection of representatives to be made that we need and merit a yet larger share of representation than the new Act of Parliament confers. If we now choose well, our representatives will hereafter hold the most influential position in the Council. They will represent the profession pure and simple, its scientific and humanitarian aims, and not the separate competing interests of the corporations, to one or more of which we are all of us none the less pleased to be affiliated. I have never been forward in medical politics, but I feel it to be desirable to support in every way independent candidates, such as Dr. Glover, Dr. Richardson, and more especially Dr. Prosser James, whom I have known intimately ever since he first entered my wards at the London Hospital in 1853. His knowledge of all branches of the profession, the position that he holds as a teacher, and the work that he has already done in the cause of reform, render him a specially eligible candidate. Dr. Prosser James is a sound general physician, who knows well from experience the needs both of the general practitioner and of the consultant, and who has done much to draw the veil of mystery from the practice of laryngology, while he has been long distinguished as an explorer in the field of laryngeal medicine since the pre-laryngoscopic times.—I am, Sir, yours truly,

W. J. LITTLE,

Oct. 18th, 1886. Late Physician to the London Hospital.

INFANT FEEDING.

To the Editor of THE LANCET.

SIR, I have read with some interest the correspondence between Drs. Thurstan and Marshall on this subject. I think both gentlemen are right and both wrong—that is to say, both are too dogmatic, and that in individual cases the views expressed by each of them would be found to be correct.

Thus, I can call to mind many infants which have thriven on half milk and half water, and cannot therefore accept as true so dogmatic a statement as Dr. Marshall makes, that "no baby can certainly be expected to tolerate milk food of such a strength at that age." Nor can I endorse Dr. Marshall's and the widely accepted teaching anent the total unsuitability of farinaceous food, "physiology and experience" notwithstanding. And, first, as regards physiology: On what basis does this teaching rest? On a few isolated experiments on young animals, from which it would seem that the salivary, and chiefly the pancreatic, juices cannot reduce starch into a soluble form! But farinaceous foods contain other principles besides starch; moreover, it remains to be proved that the reduction of starch is necessary to health in infants. And, secondly, as regards experience: it would be just as true to say that experience teaches the value of farinaceous feeding; for few, if any, children of the poorer classes are brought up from infancy onwards without some farinaceous food, and enjoy the most vigorous health notwithstanding. I fear we doctors are all too apt to argue that because certain diets are unsuitable for some children they are unsuitable for all. I have long since given up all belief in "the physiological dyspepsia for starchy food in infants," originally promulgated in this country, I believe, by Dr. Prospero Sonsino, of Pisa, in the *Practitioner*, when the late Dr. Anstie was its editor. A firm believer in this very plausible doctrine, I once acted on it to the best of my ability, and unconsciously shut my eyes to facts everywhere staring me in the face. When my advice not to give foods to infants was always met by the statement that child after child never began to thrive until something over and above milk (breast or otherwise) was given, I began to ponder these things and to argue that I was taking too narrow a view; and when I again studied the question from the physiological standpoint and found on what an insufficient basis this physiological apepsia rested, I began to think that the testimony of sensible matrons, backed by a surrounding of healthy children, was a more reliable guide than the admixture of perhaps faulty physiological observations on animals, and of experience gained very largely from the sick and mismanaged children whom we meet with in our professional avocations.

I agree with Dr. Thurstan's opinion that the addition of a little thickening to milk renders the curd more digestible, probably by causing it during digestion to be more finely and uniformly divided. The reduction of the "caseine to digestible limits" is a troublesome and an expensive process, that cannot be easily carried out in those families which are most likely to require it. It must be remembered too, that it is not so much the quantity of the caseine as its behaviour in presence of the digestive juices which distinguishes human food from cow's milk.

Dr. Marshall's argument that failure with this or that diet depends not on the diet itself so much as on the mode of its administration applies to every kind of feeding. I think he will agree with me that even wholesome breast milk may be given in such quantities, and so frequently, that a child may become ill. How much more strongly does this argument apply to artificial food! His advice to keep

to one dairy rather than to one cow is sound, provided the milk is good. The great fallacy about "one cow" milk is that it is constantly varying in quality. But there is no objection to give such milk, if, after trial, it is found to agree with the child. In country places this is quite a common and, I think, a very wholesome practice. The next best thing is to give an average milk, such as results from mixing together that from a large number of cows. I do not think we need fear "the disturbing influences of menstruation" in either case; for the generality of cows are stocked on the occurrence of the first menstrual period after calving, and, if impregnated, there is of course no recurrence.

The chief ingredient in farinaceous food which is held by authors to be so detrimental to the infantile digestion is the starch, one of the blandest and most universally distributed substances in nature. I cannot and will not believe that the minute quantity of starch which an infant consumes, even if fed entirely on farinaceous food, can bring about the serious mischief which is attributed to this kind of food. There are doubtless infants who cannot digest farinaceous food, just as there are infants who cannot digest milk in any shape. But we must consider these cases as exceptional, and regard them as instances of congenital dyspepsia, and not amenable to ordinary rules. On the other hand, there are infants with whom certain diets seem to disagree. Before condemning the diet, let us be quite sure that the child's stomach is in a condition to digest anything properly. Some months ago I was consulted about a puny infant who could not keep anything on the stomach; all kinds of diet and of drugs had been previously tried, so I decided on the following treatment:—I passed a tube into the stomach, and with a syringe poured in a quantity of warm water containing a little sodium carbonate; then reversing the current I emptied the stomach; this was repeated until the water returned almost pure. A small opiate was then administered; when the child was asleep, some nutrient suppositories were introduced into the rectum. The child was kept asleep more or less for twenty-four hours, and nourished with the suppositories, a few teaspoonfuls of warm water being given from time to time. The effect of this treatment was remarkable, and the progress the child made within a week most gratifying. I have tried the plan in an older and more chronic case, with satisfactory but not such marked results as in the first case. In these cases, it was not merely a question of diet, but of undoing the mischief which previous mismanagement had set up.

I am, Sir, yours &c.,

London, Oct. 18th, 1886. ROBERT WILLIAM PARKER.

TREATMENT BY MASSAGE.

To the Editor of THE LANCET.

SIR,—The arguments advanced by Dr. Sturges in his letter of the 9th inst. are so completely answered by his second communication and by Dr. Playfair's letter that it seems hardly necessary for me to say much more on the subject. Dr. Sturges regards Dr. Playfair as the highest authority on massage in this country; whilst Dr. Playfair himself assures us that he has never seen massage employed, and does not care how it is done. Dr. Playfair's admission that the striking results he has obtained in certain nervous diseases are due in a great measure to the removal of unwholesome domestic surroundings is in itself a convincing proof that he is speaking, not of massage—in which isolation plays no part,—but of the special mode of treatment associated with his name. Dr. Playfair evidently regards massage and the Weir Mitchell treatment as synonymous; whilst, curiously enough, Dr. Sturges now admits that they are not to be confounded. Dr. Playfair laments that massage threatens to become the prevailing folly of the day, but he does not tell us who is responsible for this unfortunate state of affairs—those who maintain that massage, depending as it does on a knowledge of anatomy and physiology, cannot be acquired in less than two years, or those who think that it is a knack like fly-fishing and tennis, to be picked up in "a few easy lessons." He tells us that when first he worked at the subject he never heard of such terms as "pétrissage" and "effleurage." This is, indeed, unfortunate, for had he taken the trouble to turn to the fourth volume of the well-known *Dictionnaire Encyclopédique des Sciences Médicales*, published in Paris in 1871, he would have found a full description of these modes of procedure. Even had he felt himself constrained to confine his attention to English writers, there is no reason why he should not have seen an article by Dr. Kent Spender, of Bath, which appeared in March, 1878, and in which both "pétrissage" and "effleurage" are mentioned by name. Dr. Playfair complains that a simple matter has been rendered complex by the introduction of these terms, but I think the difficulty has arisen from the persistent manner in which recent writers have thought fit to ignore the works of their predecessors.

I am quite sure, as Dr. Sturges says, that it would have given him no trouble to get together a list of authors on massage, and can only regret that he should not have done so, and even made himself acquainted with their writings. I think he is mistaken in supposing that in Great Britain only a languid interest is felt in massage, and that it will never take root in this country. Until recently hundreds of patients were sent abroad to undergo the treatment they could not get here, and would still be unable to obtain it if the primitive modes of training advocated by Dr. Sturges were generally adopted. I fully accept his statement that he has not read my book, although that admission may seem to detract somewhat from the value of the column and a half of detailed criticism with which he favoured me. I am obliged to him for his assurance that he will not stand between me and my readers, although it had not occurred to me that there was any danger in that direction. Dr. Sturges, in his anxiety to defend his "own hospital sisters and nurses" who were not attacked,—seems for the moment to have forgotten that they are not his only colleagues.

I am, Sir, your obedient servant,

Weymouth-st., W., Oct. 1886. WILLIAM MURRELL, M.D.

To the Editor of THE LANCET.

SIR,—In my reading the other day I came upon the following:—"Sydney Smith, speaking of being shampooned at Mahomed's baths at Brighton in 1840, said 'they have squeezed enough out of me to make a lean curate.'" At that time it was as common for physicians and surgeons to have a list of "rubbers" for their patients as of surgical and monthly nurses. Mr. Grosvenor, the well-known Oxford surgeon, long before this used the art in the treatment of his patients.

I am, Sir, yours, &c.,

Oct. 1886. C. H.

INDUCTION OF LABOUR IN CERTAIN SEVERE CASES OF ALBUMINURIA IN PREGNANCY.

To the Editor of THE LANCET.

SIR,—The case published by Dr. Cullingworth in your issue of Sept. 18th presents many points of interest. The injection under the skin of ½ grain doses of nitrate of pilocarpine once a day for three successive days had no effect whatever, although a freshly prepared solution was used. Now, pilocarpine is a very powerful drug, and if no effect whatever was produced by its administration, I should be more inclined to think with Dr. Murphy that the specimen used was inert, rather than that the disease from which the patient was suffering neutralised its usual effects. It would be interesting to learn whether Dr. Cullingworth proved by experiments that the solution he used was potent. The same remark applies to his subsequent use of the liquid preparation of jaborandi administered internally. No effect whatever was produced, and so jaborandi and its active principle, pilocarpine, were considered useless. I do not think Dr. Cullingworth gave these drugs a proper trial; he ought to have obtained profuse perspirations by the subcutaneous injection of pilocarpine, repeated not at intervals of one day, but of fifteen minutes, for if sweating does not come on directly it will not come on at all.

In a case of pregnancy with albuminuria and convulsions which I published in THE LANCET of April 3rd this year, the first specimen of pilocarpine used did not make the patient sweat, or stop the convulsions, or produce any other visible effect. I believed, and still believe, that the solution used was useless, and did not really contain pilocarpine in an active form; for when I got a fresh solution I at once obtained the physiological effect, and there were no more fits.

Dr. Cullingworth says he used a fresh solution, but I think he will admit that he might have repeated the injections at short intervals until he obtained the sweating. If he could

not make the patient sweat or salivate her with pilocarpine, that would be a very interesting physiological fact; but I apprehend that it is the sweating which does the good in these cases of eclampsia and albuminuria, and indeed Dr. Cullingworth's case would support that view if he had used it in larger doses or at shorter intervals, because no sweating was caused and no good done. But, as it stands, I think this case must be looked upon as one in which pilocarpine was not sufficiently tried, and if that be true the deductions drawn from it in reference to its ecbolic properties must also fall to the ground.

In recommending repeated injections of pilocarpine I must warn anyone who intends to give it a trial should opportunity afford, that it is a very potent drug, and will produce alarming symptoms of cardiac failure if too much is used; in such a case atropia should be at once injected hypodermically.

I am, Sir, yours truly,

St. Thomas's-street, S.E., Oct, 19th, 1886. P. HORROCKS.

TREATMENT OF TUBERCULAR MENINGITIS.

To the Editor of THE LANCET.

SIR,—In the annotations of Oct. 9th I notice a paragraph headed as above, in which 1 to 5 iodiform ointment is said to have produced wonderful effects, in the hands of M. Warfwinge, in the treatment of the above disease. I desire to call your readers' attention to the following points. Tubercular meningitis can only be diagnosed with certainty by post-mortem examination, therefore we must take with great caution any statement of a cure having taken place. It is simulated by typhoid, so as to be with great difficulty distinguished from it. The same may be said of suppurative pericarditis. Tubercular meningitis is an affection of the brain depending upon general acute miliary tuberculosis, and is usually accompanied by a deposit of nodules in and upon the lungs, pleuræ, liver, spleen, and kidney. Tubercular meningitis cannot be considered as a disease *per se*, although, owing to the fact that effusion into the ventricles of the brain, when excessive, produces death rapidly, it is convenient to consider separately this phase of tuberculosis. The effusion into the ventricles is caused by occlusion of the vessels by nodular growths of tubercle in their walls. If the iodoform rubbed into the scalp cured tubercular meningitis, then it must cure general miliary tuberculosis, as the head affection is only one of the expressions of this general disease, which it modifies so as to make it hardly recognisable. Thus, in a case of tuberculosis complicated with meningitis and effusion into the ventricles, we have the temperature never above 100°; pulse from 80 to 100, up to the day of death, when it becomes rapid—156 or more, whereas in the acute tuberculosis uncomplicated with effusion, we have a pulse of from 152 to 190, and a temperature of from 103° to 104·5°. In the first case, with meningitis, death takes place in from seven to fourteen days, and the patient is insensible most of the time; in the second, with the same general disease, minus the effusion, we have death occurring at the end of from fifteen to thirty days, and the patient is often sensible to the very last.

I am, Sir, yours truly,

MARTIN OXLEY, M.D.,

Oct. 15th, 1886. Consult. Phys., Liverp. Infirm. for Children.

"FRACTURE THROUGH THE UPPER EPIPHYSIAL LINE OF THE RADIUS."

To the Editor of THE LANCET.

SIR,—Mr. Batterham, writing to THE LANCET of Oct. 23rd, makes a few remarks on a short note of mine which appeared in your issue of Oct. 2nd, on a case in which a fracture through the clavicle and another through the upper epiphysial line of the radius occurred as the result of indirect violence in a child aged nineteen months. The general purport of his letter is to question the accuracy of my diagnosis, and (he himself not having seen the case) to prove that the fracture through the radius was not a fracture at all, but a subluxation of the orbicular ligament. In the first place, I gave no physical signs whatever on which Mr. Batterham could either question the correctness of my statement as to what occurred, or, on the other hand, found a hypothesis of his own. Not thinking it necessary to put down the exact process whereby I arrived at the diagnosis, and in order to economise space, I merely said that such a fracture was diagnosed. The age of the patient (nineteen months) and the nature of the accident (forcible traction on the arm) were both, it is true, against the *probability* of the lesion having been a fracture—that is, supposing the clearer logic of physical signs had been absent,—and if Mr. Batterham will look back he will see that I said as much in my note. The fact that the arm hung down helplessly has nothing to do with the point under discussion, being obviously due to the coexisting fracture of the clavicle. The physical signs, which, as I said, were omitted for the sake of brevity, and on which the diagnosis of the lower fracture was made, were as follows:—Crepitus, which I took to be genuine and not spurious; some slight displacement of the upper end of the shaft, which displacement, having been once reduced, could without the exercise of any force be reproduced; non-participation of the head of the radius in movement communicated to the lower end. Beyond this, there was, when the fracture apparatus was removed, an irregular thickening around the upper end of the bone which I at the time certainly associated with callus. I may perhaps add that Mr. Rich, assistant-surgeon to the infirmary, also saw the case, and after a careful examination entertained no doubt as to the accuracy of the diagnosis. The case, from the fact that a fracture was caused in a child's radius and clavicle by indirect violence, and from the fact that the fracture of the radius occurred, as I believe, through the upper epiphysial line, was doubly interesting and uncommon, otherwise I would not have reported it.

In conclusion, may I offer to Mr. Batterham my thanks for his well-meaning efforts for my better instruction in the diagnosis of fractures of the radius, whilst at the same time I trust he will forgive me if I take the liberty of adhering to my original opinion formed on actual observation of the case.

I remain, Sir, your obedient servant,

ALEX. FOULERTON, M.R.C.S., L.R.C.P.,
Resident Medical Officer, Royal Isle of Wight Infirmary.

Ryde, Oct. 24th, 1886.

THE MEETING OF GERMAN NATURALISTS AND MEDICAL MEN IN BERLIN.

(Continued from p. 706.)

THE sectional meetings could not be so arranged as not to clash with each other, and in reporting the principal work done I have to rely partly on the official record which, in the form of a daily journal, was published at the time, and occupies no less than 450 quarto pages. The whole of this was in the hands of the members a few days after the termination of the meeting, thanks to the indefatigable labours of the publishing committee (Drs. Guttstadt Guttmann, and Sklarek) and the secretaries of the several sections.

In the Section of Physiology, Cerebral Localisation as shown by the experiments on animals formed the subject of discussion, which led to some unpleasant personal observations. Hitzig maintains his views as to the existence of motor centres in the brain; Goltz, on the other hand, reiterated the views which he had already expressed at the International Medical Congress in London and elsewhere, and especially challenged the observations of Munk on the visual centres situated in the cortex of the occipital lobes. Munk, on the other hand, showed dogs in which the cortex of the occipital lobes had been removed, and whereby the animal was rendered blind, and exhibited the brains of four dogs in support of his views. The discussion was continued by Fritsch, Christiani, Meynert, and others, but led to no practical conclusions. However divergent the results from experimental observations on animals may be, the researches of Ferrier and Horsley clearly demonstrate that for man at least the existence of separate motor centres cannot be disputed. Flesch spoke of some histological researches which showed that those regions of the cortex which had different physiological functions also had different histological structures, and that the various regions showed abrupt changes. This view was combated by Meynert, who alluded to his own observations and those of Lockhart Clarke. Many other papers of great physiological interest were read: such as the Physiology and Histology of the Secretion of Mucus, by Biedermann; and the Reduction of Hæmoglobin in the

Heart of the Frog, by Kronecker. The observations showed that the more quickly the hæmoglobin is reduced, the oftener is the heart irritated, and the warmer it is; but that the reduction is independent of the work done by the heart's muscle or its tension. According to Röhmann's observations on the formation of lactic acid during the activity of the frog's muscle, lactic acid is formed and glycogen diminished. A small part of the lactic acid thus formed in the muscle goes to the kidneys and passes out by the urine; the larger proportion, however, passes into the liver and is there destroyed.

In the Section of Pathology and Morbid Anatomy, Knoll read a paper on the Pressure Variations in the Cerebro-spinal Fluid, and dwelt particularly on the fact that the vessels of the central nervous system remain unaffected when the vessels of the other parts of the body undergo contraction. Professor Chiari spoke of a peculiar form of Orchitis which he observed in persons, chiefly boys, who had died of small-pox. This affection seems to occur during all the stages of small-pox, and is characterised by isolated patches of inflamation, going on to necrosis. Schron gave an account of some observations on the Genesis of the Tubercle Bacillus and its development from Spores, and exhibited a number of preparations. The majority of the members present were, however, very sceptical as to the correct interpretations of the appearances seen in the preparations. Prof. Ponfick read a paper on the Formation of Biliary Colouring Matter in the Circulatory System, and Prof. v. Recklinghausen expressed his belief in the existence of true hæmatogenic icterus, chiefly characterised by the presence of hæmatoidin or bilirubin crystals in the blood. The Formation and Composition of the White Thrombus was the subject of two communications. Löwit's observations were directed chiefly against the views of Eberth and Schimmelbusch on the part which the blood plates play in the formation of the white thrombus. He believes, with Zahn, that the leucocytes form the chief component parts of the thrombus. Weigert followed with a new staining method, demonstrating that the thrombus seen in man contains a large amount of fibrine and leucocytes. The method he employs for staining micro-organisms is Gram's. Instead of placing the preparation in alcohol, after taking it out of iodine solution, he washes it with aniline water, when the fibrine appears deeply stained. Professor Virchow exhibited a number of very interesting preparations, and spoke of general hyperostosis of the skeleton with formation of cyst. The medulla of the bone contained compact bony tissue of ivory-like hardness, islets of fibro-cartilaginous tissue, and cysts. These changes have a close resemblance to those seen in Paget's disease—a view which was also expressed by Recklinghausen. Virchow is inclined to look upon them as arising from enchondromata. Professor Grawitz exhibited museum specimens which were prepared in a peculiar manner. The preparations so preserved kept their colour, size, form, and consistency. They may be kept in this way for some weeks, and the method is therefore very useful for teaching purposes. The following is the composition of the preserving fluid: 150 grms. of sodium chloride, 20 grms. of saltpetre, to 1 litre of water; to this is added 3 per cent. of boracic acid or tartaric acid. The method further recommends itself on account of its cheapness (1 litre costs about 1*d.*). Paltauf exhibited pure Cultivations of a Micro-organism seen in rhinoscleroma (cultivated from the expressed juice in six cases). These organisms resembled the pneumococcus of Friedländer alike in their naked-eye cultivations, their microscopic appearance, and their behaviour when injected into mice. Arning showed some beautiful microscopic preparations of Lepra Bacilli, and demonstrated their presence in the nerves in lepra anæsthetica. He succeeded in preserving the bacilli in putrefying fluids, and found that they increased in quantity when so kept. Neither Arning nor Schottelins succeeded in inoculating animals with lepra.

A brief account of the more important papers in some of the other sections I shall refer to in my next communication.

AT a meeting of the executive committee of the Merthyr and Dowlais proposed hospital on the 23rd inst., it was announced that at least £2000 beyond the subscription of £1000 conditionally offered by Lord Bute towards such an institution had been promised, and the project is now, therefore, fairly afloat.

LIVERPOOL.

(From our own Correspondent.)

THE PREVALENCE OF SCARLATINA.

ALTHOUGH scarlatina prevails to a very considerable extent, the cases are not very severe, and there would be little to regret were it not for its very contagious nature, and the fact that so many cases are treated at home instead of in hospital, where, under the circumstances, they should be. It is to be hoped that the suggestions given in last week's LANCET will be adopted, and that every advantage will be taken of such hospital accommodation as presents itself, and that the sanitary, ventilating, and other arrangements of the hospital are what those of a fever hospital of the present date ought to be.

AN IMPORTANT REGULATION EVADED.

A lodging-house-keeper was, on the 27th inst., summoned before the stipendiary magistrate, and fined 20*s.* and costs for not having reported to the medical officer of health a case of scarlatina which had occurred in his house. The case came under the Common Lodging Houses Act, 1851, and the magistrate considered the regulation a most important one.

THE LOCK HOSPITAL.

Both the male and female wards of this hospital have been recently nearly filled with very severe cases. By a coincidence Mr. Lowndes was able to add confirmation to the other modes of diagnosis in the case of two male patients affected with syphilis, the female from whom they contracted the disease, a prostitute, being also in the hospital. All three were suffering from primary sores and papular eruption. It is another proof of the defect of the volunteer system and of the need of legislation to prevent the spread of syphilis that this woman insisted upon taking her discharge, and resuming her life of prostitution, although she was, as our French *confrères* would term it, "in full bloom of syphilis." Mr. Lowndes has also under his care two females who, though aged respectively twenty and nineteen, are imbeciles, and therefore the men who infected them would, if traced, be liable to a criminal prosecution under the Criminal Law Amendment Act, 1885.

A TERRIBLE DEATH.

An inquest was held at St. Helens, on the 27th inst., by the county coroner, on the body of a man who had been employed in some chemical works. On Saturday, the 23rd inst., he was standing on the edge of a caustic pan when he missed his footing and fell into the boiling caustic. He was got out and taken to the Providence Hospital, where he died the same night. The Government Inspector who had visited the works and made full inquiries, stated that the accident was entirely owing to the dangerous and unnecessary practice adopted by deceased.

Liverpool, Oct. 27th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SHERBURN HOSPITAL.

SOME interesting facts relative to this hospital, which is situated about two miles and a half east of Durham, have just been published by the master, the Rev. H. A. Mitton. It was founded about 700 years ago by the well-known Bishop Pudsey, and was designed for the reception of lepers of both sexes. How and at which period Eastern leprosy arose in England may be a matter of doubt, but fortunately it became almost extinct about the middle of the fifteenth century, and the hospital revenues were thenceforward appropriated for the maintenance of poor persons. Mr. Mitton says that in 1500 it was found that "the master, like many predecessors, was pocketing the revenues of the house," and it was not until thirty years later that this and other abuses were swept away. Since the reconstitution of the hospital in 1857 its usefulness has been considerably extended. Part of its revenues is now applied to the maintenance of thirty old men, fifteen of whom [illegible] out-brethren, and receive a

pension of 8s. per week. The in-brethren are provided with lodging, food, and clothing, and 4s. per week for minor expenses. The infirmary for patients, erected at a cost of £12,000, is a main feature of the charity. It is a large building, forming with the church one side of the quadrangle, capable of containing, with separate rooms, thirty patients—fifteen of each sex. A resident medical officer superintends these. The third main department in the scheme of the modern dispensation of the charity is the dispensary. Here five days in the week gather together a large company of sick and impotent folk from all parts of the county of Durham—Mr. Mitton says, "waiting patiently for their interview with the skilful and genial medical officer, Dr. Lionel Booth." Four thousand tickets yearly are issued to the clergy and large employers of labour in the diocese, and as these are all used, and as each order brings an average of five visits before it expires, this means about 20,000 medical consultations and medicine in the year. The dispensary is very popular, and was erected at a cost of £2000. It is quite separate from the infirmary. It includes the most complete arrangements for its purpose, and has a long shed for vehicles, which is sometimes filled on the dispensary days. Mr. Mitton says in his very interesting account—of which I merely give you a brief abstract—that "it is scarcely possible to exaggerate the amount of good effected through this department," but he also says that the main difficulty is to exclude those who are not really objects of charity, and it is to be regretted that orders are occasionally given, notwithstanding the express printed directions, which have to be cancelled on presentation.

SCARLET FEVER AT CONSETT.

At the last meeting of the Consett Local Board, the subject of scarlet fever, which has been epidemic in the neighbourhood for some time past, was considered. Dr. George Renton reported why the epidemic had not been got rid of, the causes being principally the reopening of the day schools, and the children being allowed to attend school from infected houses, as well as the funerals of schoolmates who had been stricken down with the fever.

NEWCASTLE.

An inquest has been held here on the body of a widow, sixty-four years of age, who destroyed herself by drinking an infusion of lucifer matches; and another case of attempted suicide by the same means is also reported. During the fortnight ending Oct. 9th the number of cases of infectious disease reported to our medical officer of health, Mr. H. E. Armstrong, reached the high total of 109; 86 of these were cases of scarlet fever, and 17 of enteric or typhoid.—The umpire appointed in the case of the North-Eastern Railway and the College of Medicine here has awarded to the College authorities £18,664. This, I believe, is nearly twice as much as was at first offered by the company to the College for their building. The Natural History Society has also been awarded £12,830 for its old building in the vicinity of the College of Medicine.

Mr. C. L. Lightfoot and Mr. G. E. Williamson are candidates for the surgeoncy at the Eye Infirmary vacated by the resignation of Dr. Heath. Mr. Williamson is a lecturer at the College of Medicine, and has had for some years charge of the ophthalmic department at the Newcastle Infirmary.

Newcastle-on-Tyne, Oct. 20th.

EDINBURGH.

(From our own Correspondent.)

THE WINTER SESSION.

THE medical classes reassembled for the winter session on Wednesday, Oct. 20th, and the work of the session is now fairly commenced. Several of the professors and lecturers delivered special introductory lectures on the opening day; Prof. Rutherford choosing the Sense of Hearing as a subject, whilst Prof. Grainger Stewart lectured on Pasteur and Hydrophobia, and Mr. Caird, who commences this year a course on Surgery in the Extra-academical School, gave a most interesting *résumé* of the History of the Foundation and Progress of the Edinburgh Royal Infirmary. Mr. Joseph Bell has retired from the [illegible] Royal Infirmary, and his place has been taken as Lecturer on Clinical Surgery by Mr. John Duncan. Mr. Duncan's introductory lecture dealt largely with the present state and future development and requirements of the school, and he especially insisted upon the necessity of an increase in the number of teachers of clinical surgery in connexion with the surgical wards of the infirmary.

DIRECT REPRESENTATION IN SCOTLAND.

The canvass for the election of a direct representative of the practitioners of Scotland is in active progress. The three candidates mentioned in a previous letter still hold the field, and there seems little chance that a severe contest can be avoided. On Friday the medical men of Edinburgh were invited to meet Dr. Bruce of Dingwall, who was accorded a very cordial reception by a fairly representative meeting of the profession in this city. No specific vote of confidence was asked for, but a motion was carried unanimously declaring that a fit candidate for the post could only be found in an independent practitioner untrammelled by official connexion with any of the schools or corporations of Scotland. This might apply equally favourably to Dr. Bruce and Dr. Sinclair, but amounted to a vote of no confidence in Dr. Morton of Glasgow. Several of the speakers at this meeting announced their intention of supporting Dr. Bruce, and it became evident that he has a strong following here, as well as in the Aberdeen district.

NEW UNIVERSITY BURSARIES.

It has been announced that Dr. Gunning, late of Rio Janeiro, has placed the sum of £5000 at the disposal of the University authorities as an endowment of eleven medical bursaries of £50 each, which are to be awarded triennially to Bachelors of Medicine or Bachelors of Science of not more than three years' standing, who shall present the best essays on the respective subjects. The subjects are Anatomy, Physiology, Zoology, Botany, Chemistry, Materia Medica, Surgery, Physic, Pathology, Obstetrics, and Public Health. The bursaries are each to be denominated by the name of some teacher of the Edinburgh School distinguished for his eminence in the branch to which each is dedicated; and the names selected corresponding respectively to the subjects in the above list are Munro, Bell, Forbes, Balfour, Black, Christison, Lister, Gregory, Thomson, Simpson, and Alison. The first competition is in April, 1887, in the branches of Anatomy, Chemistry, and Physic; and in the following year the subjects are Physiology, Botany, Surgery, and Pathology. The essays must be handed in before April 30th of each year.

THE RECTORIAL ELECTION.

The nomination of candidates took place last Saturday at a meeting held for the purpose in the old University Buildings. Lord Iddesleigh and Sir Lyon Playfair were nominated; and on a show of hands, the chairman, Mr. C. W. Cathcart, declared the result in favour of Lord Iddesleigh; but, upon the challenge of the chairman of the Liberal committee, appointed Saturday, the 30th, as the date for deciding the contest at the poll.

Edinburgh, October 26th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

AT a meeting of Convocation held on the 27th inst., Dr. Whitla was elected a Representative of Convocation on the Senate of the Royal University for the ensuing three years. The other two candidates were Dr. McMordie and Mr. M. J. Farrelly.

DIRECT REPRESENTATION OF THE PROFESSION IN IRELAND.

At a numerously attended meeting of Limerick practitioners, held on Saturday last, the following resolution, proposed by Dr. Fitzgerald and seconded by Dr. O'Connor, was unanimously agreed to:—"That we adopt Dr. Laffan as candidate for the seat on the General Medical Council created by the late Act, and we urge on all provincial practitioners to sustain the man who has not only the support of the leading organ of the profession, THE LANCET, but is the only Nationalist before the constituency, and the only candi-

date whose freedom from connexion with all the interested corporations alone fits him among all the competitors for independently defending the interests of the general practitioners."

DUBLIN WATER-SUPPLY.

The citizens of Dublin are supplied with an excellent water for drinking and dietetic purposes; and repeated analyses have shown that the water-supply is a sound and healthy one. Recently, however, Dr. Reynolds, Professor of Chemistry in the University of Dublin, has drawn attention to apparent insufficient filtration in the water supplied to the citizens. He states that for some time past he has found in it numerous and active living organisms, leading to the conclusion that the care of the filter beds and supervision of supply are among the arts lost to Dublin. Sir Charles Cameron, medical officer of health and city analyst, I am informed, some time since, in making an analysis of some of the water supplied to houses in the Pembroke township, discovered the presence of animalculæ in large numbers, and was of opinion that these organisms arose from the presence of eels, which got jammed in the mains or supply-pipes, and, dying rapidly, putrefied. The screen chamber, he believes, is not an effective filtering apparatus, but the filter beds in co. Wicklow are perfect. If similar beds are constructed at Stillorgan, they would cost about £50,000. Sir C. Cameron considers that the presence of these organisms is purely local.

MEASLES IN WEXFORD UNION.

It was reported that an outbreak of measles existed in Drinagh district, and last week the Local Government Board wrote in reference to this matter, requesting the Board of Guardians to obtain a report from the medical officer on the subject. The statement, however, was inaccurate, as Dr. Pierce, the medical officer, has reported that measles has disappeared from Drinagh, and that the cases which had come under his observation were of a very mild type.

ILLEGAL DISPENSING

and the unauthorised sale of poisons are carried on to a large extent in various parts of Ireland. The attention of the Pharmaceutical Society of Ireland has been called to this matter, and they have instituted prosecutions, obtaining convictions against several persons in co. Meath for these practices. They are determined to put the law in motion in every case that may be brought under their notice. If the Society or some other body were to prosecute pharmaceutical chemists for counter-practice, they would confer a great benefit on medical practitioners, more especially in Dublin.

The President of the Royal College of Surgeons, Ireland, Sir William Stokes, gave a reception last week at his residence in Merrion-square, which was attended by the principal members of the profession practising in Dublin.

The first of the introductories for the present session was given by Professor Fraser at the School of Surgery of the Royal College of Surgeons, Ireland, on Monday, the 25th inst.

Dr. Sweetnam of Schull has been unanimously elected medical officer of Glengariffe Dispensary, in the vacancy caused by the resignation of Dr. P. Cotter.

Collections in aid of the Dublin Hospital Sunday Fund will be held this year on Nov. 14th.

Dublin, Oct. 25th.

ROYAL COLLEGE OF PHYSICIANS.

THE ordinary comitia of the Fellows was held on the 28th inst., Sir W. Jenner, Bart., President, in the chair. Eight gentlemen were admitted to the Membership of the College.

A report upon the so-called Penjdeh Sore by Dr. Owen was received from the India Office.

It having been pointed out that the "Certificate in Hygiene" granted by the College does not verbally fall under the head of diplomas in public health, sanitary science, or State medicine, now registrable, the question of the desirability of a change in title of the certificate was referred to the Council.

The annual accounts were submitted, and the report of the Finance Committee was received and adopted. On the motion of the President it was unanimously resolved to present a copy of the autotype facsimile of Harvey's Prælectiones Anatomicæ to H.M. the Queen, and another to H.R.H. the Prince of Wales. The thanks of the College together with presentation copies of the work, were also voted to Mr. Edward Scott (who had bestowed great care in the difficult labour of transcribing the text), to Sir E. Sieveking, and Dr. N. Moore.

A report from the Committee of Management was received and adopted. It provides for the staff required at the new Examination Hall, and introduces the following important regulations relating to candidates referred at the Second and Third or Final Examination of the Examining Board.

"*Second Examination.*—A candidate referred on the Second Examination is required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teacher or teachers, in a recognised place of study, his anatomical and physiological studies, or his anatomical or physiological studies, as the case may be, during a period of not less than three months subsequently to the date of his reference.

"*Third or Final Examination.*—A candidate referred on the Third or Final Examination is required, before being admitted to re-examination, to produce a certificate in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, at a recognised hospital, for a period of not less than six months subsequently to the date of his reference; and, in regard to midwifery, a certificate of having received, subsequently to the date of his reference, not less than three months' practical instruction in that subject by a recognised teacher."

Dr. Ord was unanimously re-elected a member of the Committee of Management.

The report of the Examiners for the College Licence was read. It stated that at the recent Final Examination 156 candidates presented themselves, of whom 91 passed.

Dr. George Johnson and Dr. S. O. Habershon were nominated Vice-Presidents of the College for the ensuing year.

Obituary.

ALFRED PESKETT, M.D. ST. AND., M.R.C.S. ENG.

THE inhabitants of the large districts of Leyton and Walthamstow sustained, on Sept. 24th, with much grief, the loss of the longest-established and one of their most able and esteemed practitioners in Dr. Alfred Peskett, who passed away in a severe attack of nephritis, at the age of fifty-eight. Dr. Peskett was the descendant of a long line of medical practitioners, and was himself the son of Dr. William Peskett of Petersfield. He received his early education under a private tutor, and subsequently served the old apprenticeship under his father. He studied afterwards at Guy's, where he was a distinguished student, and at the end of his curriculum in 1850 he graduated M.D. St. Andrews, and obtained the M.R.C.S. Eng. He shortly afterwards commenced practice at Leyton, where he married Miss Jane Collins, only daughter of Robert Collins, M.D., and in this same town he remained till his death an active and trusted practitioner for thirty-five years. He got through an enormous amount of work in his lifetime. He was medical officer of health for Leyton, surgeon to the West Ham Union, and public vaccinator and surgeon to the Leyton and Walthamstow Children's Hospital. In whatever position he found himself, whether as medical officer of health or surgeon to the patients of the West Ham Union, or with his private patients, he always did his work intelligently, assiduously, and to the happiness of all with whom he was brought in contact. Dr. Peskett was a dignified and courteous gentleman. Amidst all his hard and incessant work he found time,

in association with his late friend and colleague Dr. George Yeates, and some of the richer inhabitants of the neighbourhood, to found and start the Leyton and Walthamstow Children's Hospital, which is now in a flourishing condition, and is a perpetual memorial of some of his good and useful work. He was also a friend to most of the literary and social societies of the district, and he had the good fortune to be the intimate friend of nearly all the practitioners of Leyton and Walthamstow. His funeral, which took place at the parish church, in the centre of the district where he had worked so long and so faithfully, was numerously attended by members of the various boards and committees on which he had worked, by most of his medical *confrères*, and by friends and patients from all parts.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Oct. 21st:

Antrobus, Edmund, Birmingham:
Ayres, Charles James, L.R.C.P. Lond., Grosvenor-road.
Boger, William Henry, Southwark.
Bray, Nicholas James Northey, Aberystwith.
Callender, Eustace Maude, Beckenham.
Colborne, William John, L.R.C.P. Lond., Southsea.
Corbett, Herbert Henry, Bolton.
Craston, Charles Anthony, Wigan.
Doyle, Henry Martin, L.S.A., Melbourne, Australia.
Gee, Frederick William, L.S.A., Regent's-park.
Gidley, Gustavus George, L.R.C.P. Lond., Honiton, Devon.
Gregory, Seth, L.S.A., Calcutta.
Halliwell, Thomas, L.R.C.P. Lond., Birmingham.
Iddon, William Henry, Southport.
Jennings, Edgar, L.S.A., West Hampstead.
Lansdale, William, Chelsham-road.
Marks, Robert John, L.S.A., Clifton, Bristol.
Mast, Theodore Arthur, Buckingham-palace-road.
Morgan, George Frederic Elliott, Sharsted-street.
Scratchley, Henry William, Taunton.
Slack, George Arthur, Uffculme, Devon.
Taylor, Arthur Sneyd, Lewisham-road.
Todd, Frederick, Catford.
Tomlinson, William Henry, L.S.A., Manchester.
Wright, Charles Franklin, L.S.A., Great Yarmouth.

Admitted on the 22nd inst.:—

Boxall, Frank, L.S.A., Horsham.
Blackler, Henry John, L.R.C.P. Lond., West Norwood.
Denton-Cardew, Henry Warnell, Bloomsbury.
Dwyer, Hubert de Burgh, L.R.C.P. Lond., Kensington.
Edsell, George Alfred, L.S.A., Upper Norwood.
Francis, John Arthur, L.S.A., Southsea.
Freeman, Richard Austin, L.S.A., Caledonian-road.
Girling, John, L.R.C.P. Lond., Colchester.
Harston, Lionel de Courcy Eagles, L.R.C.P. Ed., Clapham-common.
Hawkins, Herbert Cæsar, Eastbourne.
Kingsford, Edward Claude, L.R.C.P. Lond., Clapham-common.
Pridmore, Walter George, Junction-road.
Roper, Harold Kennaway, L.R.C.P. Lond., Upper Norwood.
Semple, Henry Frederick, L.R.C.P. Lond., Redlands, Bristol.
Thomas, Frederick, L.R.C.P. Lond., Penarth, Glamorgan.

Admitted on the 25th inst.:—

Boase, Richard Davey, L.R.C.P. Lond., Plymouth.
Cox, James Herbert, L.R.C.P. Lond., Cape Town.
Dewes, Frederick Joseph, L.R.C.P. Lond., South Lambeth-road.
Freeman, Charles Delamark, Marylebone-road.
Kelsall, Charles James Seddon, L.R.C.P. Lond., Bayswater.
Miller, Frederic Richard, West Liss.
Mortlock, Charles, L.R.C.P. Lond., Kensington-park.
Muriel, John, Halligh, Suffolk.
Nelham, Albert Edgar, Warwick-street.
Popert, Alfred William, L.R.C.P. Lond., Anerley.
Sloman, Frederick, Faraham.
Vernon, Frederick William, L.S.A., Plaistow.
Williamson, Charles Frederick, L.R.C.P. Lond., Mildmay-park.
Wood, George Edward Cartwright, L.R.C.P. Lond., Portobello.

Admitted on the 26th inst.:—

Agnew, Edward Dalton, L.S.A., Soho-square.
Brown, Charles, L.R.C.P. Lond., Wandsworth-common.
Harper, John Maurice, South Hackney.
Ingleby-Mackenzie, Kenneth W., L.R.C.P. Lond., Guilford-st.
Jackson, William E. Gillson, L.R.C.P. Lond., Addington-street.
Lambert, Frederick Samuel, L.R.C.P. Lond., Red-hill.
Macevoy, Henry Thomas, L.R.C.P. Lond., Camden-road.
Manton, John Albert, L.R.C.P. Lond., Wakefield.
Moxon, Alban Henry, South Hackney.
Michell, John Charles, L.S.A., Taunton.
Pearson, Richard, L.R.C.P. Lond., Westbourne-park.
Thomas, Josiah Telfer, L.R.C.P. Lond., Camborne.
Winfield-Roll, Grahame, L.R.C.P. Lond., Brighton.

[In the list of candidates who passed on the 20th inst., for "Ashley" read Ashby.]

UNIVERSITY OF DURHAM.—On the 26th inst. the degree of M.D. was conferred on

Frederick Imcock.

VICTORIA UNIVERSITY.—The following gentleman has been approved for the Degree of Doctor of Medicine:—

Edward Gordon, M.B. Owens College.

The following gentleman has satisfied the Examiners in Part II. of the Final M.B. Examination (First Division), also distinguished in Obstetrics and Diseases of Women:—

O. J. Kauffmann, Owens College.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the October sittings of the examiners the following candidates passed the Examination for the Licence and were admitted Licentiates:—

Gibbon, William, L.K.Q.C.P.I., The Asylum, Carmarthen.
Madders, Charles, L.K.Q.C.P.I., Rathmines.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.—The dinner of the Association will be held on November 4th at the Café Royal, Regent-street.

THE Hull Sanitary Congress will hold its annual meeting on November 10th. The Archbishop of York will, it is expected, again preside.

THE collection made by the General Post Office towards the Hospital Saturday Fund amounts this year to £341 19*s.*, as against £326 6*s.* 9½*d.* last year.

IT has been decided to amalgamate the Sunderland Hospital for Sick Children with the local infirmary, and to erect a new wing at the latter institution, to be devoted to the separate treatment of children.

THE death is announced at York of Mr. Alfred Hill, L.S.A., L.R.C.P. Ed., at the comparatively early age of thirty-eight. The deceased had been in failing health for some considerable time.

DR. DYKE, an old and esteemed resident in Merthyr Tydvil, well known as medical officer of health for the borough, took his seat on the local bench of magistrates for the first time on the 23rd inst.

ON the 23rd inst. the summonses against several inhabitants of Old Windsor, charging them with having damaged some of the tents erected by the urban and rural sanitary authorities on land near the Thames, were withdrawn.

PRESENTATION.—Dr. Presslie has, on the occasion of his marriage, been presented with a handsome silver drawing-room clock, with ornaments, by the members of the Aberdeen Society of Chemists and Druggists, as a token of their appreciation of his services to the Society.

HARROGATE MEDICINAL WATERS.—On the 22nd inst. the Mayor of Harrogate performed the ceremony of turning on water into a series of reservoirs constructed by the Corporation for the conservation of the various medicinal waters from the springs with which the town abounds.

MUNIFICENT BEQUEST.—By the will of the late Richard Mount, Esq., of Canterbury, the Maidstone Ophthalmic Hospital becomes entitled, on the death of his widow, which has just taken place, to £10,000, whilst a similar institution in London profits, it is stated, to the extent of £30,000.

UNIVERSITY OF CAMBRIDGE.—Notice has been issued that the examinations for the degrees of M.B., B.C., and M.C. will begin as follows: First and Second M.B. Examinations, Dec. 3rd; Third M.B., Part 1, Dec. 14th; Part 2, Dec. 15th, B.C. Examination, Dec. 18th; M.C. Examination, Dec. 17th. The names of candidates for the Third Examination and for the examinations in Surgery must be sent to the Registry (through the Prælectors of their respective Colleges) on or before Wednesday, Dec. 1st, those for the First or Second Examinations on or before Tuesday, Nov. 23rd. The certificates of candidates, accompanied by their postal addresses, should be sent to the Registry not less than seven days before the beginning of the examination for which they are entered. The fees for the examination must be paid to the Registry when the certificates are sent in.

VACCINATION GRANT.—Mr. Walter Hutchinson, public vaccinator of the second district of the Newmarket Union, has been awarded the Government grant for efficient vaccination.

TAUNTON AND SOMERSET HOSPITAL.—The annual report, which was read on the 25th inst. at the general meeting of the governors of this institution, stated that the financial position of the hospital was still in an unsatisfactory state, the expenditure during the past year having exceeded the income by £574.

IT is proposed to hold a meeting of the various scientific societies in Australia and New Zealand in 1888 (the hundredth anniversary of the foundation of the colonies), upon the lines of the British Association meetings, and to form an Australian association for the advancement of science, with similar aims and objects.

CREMATION.—The eighth cremation took place at the crematory at St. John's, Woking, on the 21st inst. The remains were those of an old lady of sixty-four, who died from cancer, and who expressly desired cremation. The ashes weighed 3¼ lb., and were removed by two of her sons for burial in the family vault.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The next quarterly meeting will be held at Bethlem Hospital, St. George's-road, London, on Tuesday, November 9th, at 4 P.M., when Dr. Hayes Newington will read a paper on "What are the Tests of Fitness for Discharge?" In the evening the members will dine together at the Holborn Restaurant.

THE NEW HAMBURG HOSPITAL.—The new town hospital for Hamburg, at Eppendorf, which is now nearly finished, is arranged on the pavilion system, and, exclusive of the buildings for administrative purposes, consists of eighty distinct pavilions; there are, besides, extensive grounds, and when completed this will be the largest and most perfect hospital in Germany.

FOOTBALL ACCIDENTS.—On the 23rd inst., during the progress of a game between the Bolton Wanderers and the West Bromwich Albion, on the ground of the latter, one of the home players had his right leg broken. On the same day, during a match at Bournemouth between Sussex and Hants and Dorset, one of the players in the latter team also had his leg fractured.

RETREATS FOR DRUNKARDS.—The sixth report of the Inspector of Retreats, under the Habitual Drunkards Act, 1879, for the year 1885, was issued on the 23rd inst. It states that during the year two new retreats had been added to the four houses already licensed under the Act, and that the management of the institutions and conduct of the patients had been during the twelve months eminently satisfactory.

THE ESSEX COUNTY ASYLUM.—On the 25th inst., Sir Thomas Barrett-Lennard, Bart., laid the memorial stone of a new block of buildings to be added to the Essex County Asylum, near Brentwood, at a cost of nearly £64,000. The new buildings are designed to accommodate 450 patients, and when they are completed the asylum will offer sufficient accommodation for all the patients in the county.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The following is the result of the competition for the Entrance Scholarships:—£125 Scholarship, open to the sons of medical men, Mr. Alfred J. Lattey; £90 Scholarship, open to students who have passed the Cambridge first M.B., Mr. W. S. Lazarus Barlow; £65 Scholarship, open to students who have passed the Cambridge second M.B., Mr. Guy Budd Courteney; £50 Open Scholarship, Mr. G. Y. Cobb Hunter; £50 ditto, Mr. Francis N. J. MacVicars.

MIDLAND MEDICAL SOCIETY.—At the annual meeting, held on October 6th, the following officers were appointed:—President: Mr. Lloyd Owen. Ex-President: Dr. Holmes Joy. Members of Council: Mr. Messiter, Mr. Bennett May, Mr. Jordan Lloyd, Mr. Harmar, Mr. Ker, Dr. Simon, Dr. Savage, Mr. Chavasse, Mr. Ross Jordan, Mr. Priestley Smith, Mr. W. Thomas, and Mr. Eales. Treasurer: Mr. Garner. Auditors: Dr. Foxwell and Mr. A. F. Clay. Secretaries: Dr. Suckling and Mr. Haslam.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARNLEY, ARTHUR N., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Wigston District of the Blaby Union.

BEATLEY, WM. CRUMP, M.D. Durh., M.R.C.S., has been appointed Honorary Physician to the Hospital for Sick Children, Newcastle-on-Tyne, vice Dr. J. G. Houseman, resigned.

BENNETT, J. R. A., M.R.C.S., L.S.A., has been appointed Assistant Medical Officer at the Workhouse of the Parish of Birmingham.

CARTER, GRAHAM A., M.D., L.R.C.S., has been appointed Medical Officer of Health for Lichfield.

COTMAN, J. S. E., L.R.C.S., M.R.C.P.Ed., has been appointed Medical Officer for the C Division of the Metropolitan Fire Brigade.

DEANE, EDWARD, L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to the Royal Berks Hospital, Reading.

GRIFFITH, WALTER, S. A., M.B.Cantab., F.R.C.S., has been appointed Physician to the Out-patient Maternity, Queen Charlotte's Hospital.

HARGOOD, WILLIAM (late Clinical Assistant to St. Luke's Hospital), has been appointed Assistant Medical Officer to the Middlesex County Lunatic Asylum, Banstead Downs.

MOSELEY, G. WILKINS, M.B.Edin., has been appointed House-Surgeon to the Royal Hospital for Children and Women, Waterloo-bridge-road, S.E., vice E. H. Freeland, resigned.

SCALLON, E. OLIVER, M.R.C.S., L.S.A., has been appointed Medical Officer for the Templecombe District of the Wincanton Union.

SMART, W. H., M.A., M.B.Cantab., M.R.C.S., has been appointed Resident Clinical Assistant to the East London Hospital for Children, Shadwell, vice B. M. Bond, Esq., resigned.

STADDON, J. R., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Bramford District of the Bosmere and Claydon Union.

TURNBULL, JAMES, M.B., C.M.Ed., has been appointed Medical Officer for the Parish of Dunbar.

Births, Marriages, and Deaths.

BIRTHS.

ALLDEN.—On the 19th inst., at Forest Lodge, Shirley, Southampton, the wife of John H. Allden, M.R.C.S., L.S.A., of a son.

DAVIS.—On the 26th inst., at 14, St. James's-square, Bath, the wife of Robert Davis, of a son.

GOSSE.—On the 24th inst., at Eccleshall, Staffordshire, the wife of Hope Wilkes Gosse, M.R.C.S., of a daughter (stillborn).

HARDWICKE.—On the 22nd inst., at Stour House, Dovercourt, the wife of W. W. Hardwicke, M.R.C.P., L.R.C.S., L.M., of a son.

MARRIAGES.

HILL—FORBES.—On the 21st inst., at St. Jude's, Southsea, Chas. Birnie Hill, Surgeon, Medical Staff, to Augusta Mary, third daughter of Captain C. R. P. Forbes, R.N.

PERN—HEYWOOD.—On the 26th inst., at the Parish Church, Eltham, Alfred Pern, F.R.C.S., to Melville Jane, third daughter of the late Thomas S. Heywood, Paymaster-in-Chief, Royal Navy.

PERRY—FLYNN.—On the 26th inst., at St. Peter's Catholic Church, Woolwich, Allan Perry, Surgeon, Medical Staff, to Agnes Lucinda, second daughter of Lt.-Colonel Flynn, Assistant Commissary-General of Ordnance.

STONHAM—TAYLOR.—On the 21st inst., at St. Paul's Church, Astley-bridge, by the Rev. George Forrester, B.A., Vicar of St. Paul's, Clapham, uncle of the bride, assisted by the Rev. T. Dickinson, Vicar of St. Clement's, Openshaw, also uncle of the bride, and the Rev. L. R. Hearne, Vicar of the Parish, Thomas George Stonham, M.D.Lond., M.R.C.S., of Claremont, Ventnor, to Lilian Isabel, eldest daughter of Rowland Taylor, Esq., Solicitor, and Coroner of Bolton, Lancashire.

DEATHS.

CHAPMAN.—On the 26th inst., at Old Friars, Richmond, Surrey, Fredk. Chapman, M.R.C.S., L.S.A., in his 73rd year.

DAVIDSON.—On the 22nd inst. (suddenly), at Marischal College, Aberdeen, Alexander Dyce Davidson, M.D., Professor of Materia Medica in the University of Aberdeen.

POUT.—On the 22nd inst., at Yalding, Kent, Henry Pout, M.R.C.S., L.S.A., aged 88.

MIDDLETON.—On the 26th inst., at Park-terrace, Didsbury, near Manchester, Thomas Middleton, F.R.C.S., in his 74th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, November 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Communications will by given by Messrs. S. J. Hutchinson, A. S. Underwood, Walter Coffin, Storer Bennett, J. H. Mummery, A. P. Reboul, W. A. Hunt, &c.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Lawson Tait: The General Principles concerned in the Operation of Removal of the Uterine Appendages.

Tuesday, November 2.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Sainsbury: Tubercular Mass in Supra-renals.—Dr. Sherrington: The Ascending Tract of the Spinal Cord.—Mr. Sydney Jones: Tumour of Palm of Hand.—Mr. Makins: Intra-bursal Fibroma.—Mr. Sutton: Cysts in neighbourhood of Hyoid Bone.—Mr. Treves: Melanosis of Hard Palate.—Mr. Paget: Tumour of Palate.—Dr. S. West: Acute Necrosis of the Fourth Cervical Vertebra. Card Specimens:—Mr. Fenwick: Calculus formed round an Umbrella Ring.—Mr. Shattock: Parts after Removal of the Ovary six months previously.—Dr. Coupland: Genito-urinary and Supra-renal Tuberculosis.

Wednesday, November 3.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARK'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Mr. Doran: Papilloma of Fallopian Tube (adjourned debate).—Dr. Champneys: On the Obstetrics of the Kyphotic Pelvis.—Dr. Dakin: Mercurialism in Lying-in Women.—Dr. Herman: Case of Lupous Stricture of Urethra.

Thursday, November 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—7.45 P.M. Hospitals for Special Diseases and Specialists (Discussion).

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Dr. T. Buzzard: A case of Nerve Lesion.—Photographs illustrative of Epilepsy in Guinea-pigs; also Surgical and Medical cases of interest.

Friday, November 5.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Exhibition of Pathological Specimens.—Dr. Owles: Notes of a case of Epithelioma of the Œsophagus and Stomach.—Mr. Keetley: Further Remarks on the Radical Cure of Hernia by Injection.

Saturday, November 6.

MIDDLESEX HOSPITAL.—Operations

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

AN APPEAL.

A LARGE number of photographs are, it appears, sent each month to the offices of the *Amateur Photographer* for editorial criticism, and many which are sent in for competition for the various prizes offered by the proprietor of that journal are never claimed. It is proposed for the future to mount these in albums, and distribute them among the poor and to charitable institutions. A distribution of this sort could be much extended by the co-operation of those who have photographs or albums of no further use to them; and for such assistance the Editor of the *Amateur Photographer* has just issued an appeal, which, especially in view of the approaching Christmas, we commend to the kindly feeling of our readers.

Dr. W. S. Griffith.—In a communication to THE LANCET on the treatment of cancer by Chian turpentine, published on Dec. 17th, 1881, Professor Clay stated that the drug he employed was obtained of Messrs. Southall and Barclay, Birmingham.

Mr. W. J. Black is referred to a general notice at the head of this column.

INTUSSUSCEPTION; INFLATION.

To the Editor of THE LANCET.

SIR,—The three cases of intussusception recorded by Dr. Cheadle in THE LANCET of Oct. 23rd are of great interest. The inflator invented by Mr. Lund of Manchester, and recommended by Mr. F. Treves in your issue of Dec. 26th, 1885, p. 1182, greatly facilitates the operation of inflation.

I am, Sir, your obedient servant,

Burt, Londonderry, Oct. 23rd, 1886. E. DONALDSON.

DESTRUCTION OF LOCUSTS.

A PHARMACIST of Huete in Spain, Don Luis Arias, claims to have discovered a remedy against the devastations of locusts in another insect which deposits its eggs within the head of the locust, the larvæ when hatched causing the death of their host.

Mr. Basil.—Mr. Allen, Marylebone-lane, will no doubt give the information required.

E. has not enclosed his card.

AN ANNOYING EXPERIENCE.

A CORRESPONDENT has forwarded us the particulars of a recent experience, in the hope that their publication will enable other medical men to avoid a similar annoyance. Our correspondent recently advertised for a qualified assistant, and received a reply from a person in a large northern town, styling himself an M.D. The references of the applicant were satisfactory, his name appeared in the Medical Directory for 1885, and our correspondent engaged him. On his arrival, however, he stated that he was not on the Register, and, after some cross-examination, admitted that though he had been registered his name had been struck off in consequence of a conviction for theft, a conviction followed by six months' imprisonment with hard labour. The theft he excused by the statement that an excessive use (or abuse) of chloral had brought on kleptomania. In consequence of this confession our correspondent felt justified in declining his services, giving him a sovereign towards his expenses, for which at the time grateful satisfaction was expressed. Subsequently, however, legal proceedings were taken to recover a month's salary and board, and our correspondent, having no time for litigation and actuated by compassion for the man's unfortunate position, has consented to a compromise. The moral is, the writer thinks, to engage assistants through a medical agent, by whom inquiries as to their antecedents are almost invariably made.

Dr. H. Cane.—We have freely expressed our opinion against an attempt to bind candidates or voters too rigidly in the election of Direct Representatives; but it would be a mistake to condemn three, as it would be to vote for three, in a group. Each candidate should be judged on his own merits, and each registered practitioner should take some pains to ascertain the claims of each candidate, whether he be one of a group, or take an independent position.

Mr. Montague H. C. Palmer.—The patient can scarcely be expected to pay, but the Accident Insurance Office ought to be charged.

Mr. Julland (York).—The paper will appear in an early number.

SALICYLATE OF SODA FOR FETID URINE.

To the Editor of THE LANCET.

SIR,—Dr. Fagge, in his valuable work on the "Principles and Practice of Medicine," has the following:—"I believe that the tendency [of urine in paraplegia] to putrefaction may be completely checked by the administration of salicylic acid or some other antiseptic medicine by the mouth." Having resolved to try it, I did so; with what success the following case will show.

MRS. T——, aged sixty, complained on Oct. 2nd, 1886, of debility, loss of appetite, pain above the pubes, with frequency of micturition and pain in the act. The pulse was weak and slow; the urine alkaline, fetid, and flocculent. The patient was ordered fifteen-grain doses of salicylate of soda, to be taken every four hours in milk. After taking two powders she complained of nausea, pain in the head, giddiness, "buzzing" in the ears, and faintness. The dose was then reduced to seven grains and a half (on Oct. 3rd), and was continued for three days, when it was increased to ten grains every four hours. The urine, on being examined on Oct. 6th, was found to be sweet, and with a decidedly acid reaction. The pain on micturition and tenderness on pressure over the pubes had subsided, the general condition of the patient being decidedly better.—I am, Sir, yours faithfully,

Mexbro', October, 1886. CECIL ROBERTSON, M.B., C.M. Aberd.

THE FOOD OF PARIS.

THE annual consumption in Paris of various kinds of food which can be closely controlled by the registers of the *octroi* was during last year 146,825 tons—an increase of 446 tons over the previous year. Of pork 148 tons had been consumed less, while the consumption of horse-flesh, with a total of 3830 tons, had augmented 337 tons, as compared with 1884; the average price of this last-named commodity is sixty centimes a kilo, while the meat of asses and mules command about seventy centimes. Of poultry and game the aggregate consumption was 25,044 tons—a slight diminution as compared with the year before. The quantity of fish, &c. amounted to 25,631 tons—a slight augmentation, more particularly in oysters. The consumption of butter and eggs has fallen off by nearly 160 tons, which decrease, so far as butter is concerned, may readily be accounted for by the greater use of margarine.

Iatros.—Every district medical officer must be registered as qualified to practise both medicine and surgery; but under very special circumstances the guardians may appoint as district officer a medical man registered with one qualification only.

L.R.C.P. & L.R.C.S. Edin., and *M.B.* are referred to the article on Books in our Students' Number.

C. C.—We think a sojourn in Germany, *after* taking the M.B., would be a decided advantage.

SIR DOUGLAS MACLAGAN.

THE Nestor of the Edinburgh School, it is well known, is hardly less proficient as an "all-round shot," whether at the target or on the moor, than as a lyric poet or clinical consultant; and the combination of attributes—in connexion with his receiving the honour of knighthood (so gracefully referred to by Principal Sir William Muir at the opening of the winter session)—has suggested to an *alumnus* and graduate of the same school the following epigram, which appeared in a northern contemporary:—

"Laganide! Tibi nascenti bene dixit Apollo:
'I puer, i musis semper amande meis.
Te civem, medicum, doctorem fama manebit
Plurima, te vatem rite sequetur honos.
Regia te claros inter Scholia noscet alumnos,
Majus Athenæo mox meriture decus.
Me duce suscipies feliciter arma Salutis,
Civibus ægrotis spe meliora parans;
Inque pharetrato grege conspicere, timendus
Quels mea cunque affert "certa sagitta" necem.
Auspice te pubes ambabus idonea fiet
Partibus: hæc vitam conflict, illa novat.
Nec, positis curis, thallarchus amicior ullus,
Seu versus fundes seu sine felle jocos.
Omne feres punctum commiscens utile dulci,
Divitibus gratus pauperibusque simul.
Teque suum decus et tutamen Edina fovebit
Donec iter facias serus in astra redux.'
Sic ait, auratoque humeros velatus amictu
In nemus arcanum Delphicus augur abit."

The following translation gives at least the sense of the original:—

"Maclagan! O'er thy cradle Phœbus smiled:
'On, favoured of my Muses! On, my child!
As patriot, physician, teacher, fame
Winged with thy verse shall waft abroad thy name.
Thy budding gifts the High School shall discern,
Yet prouder bays for Academe thou'lt earn.
With me for guide thou'lt ply the healer's art,
And health unhoped for to the sick impart.
Thy peers in archery thou'lt so outshine,
The foe shall take thy swerveless shafts for mine.
Through thee in Scotia's youth my power shall blend—
My power of death to foe, of life to friend.
And in free festal hour, as host or guest,
Thou'lt charm with lightsome lay, with genial jest.
Of high and humble the beloved alike,
The happy mean of work and play thou'lt strike.
So thee, Edina, as her joy and stay,
Shall cherish till thy late assumption-day!'
Thus spoke the Sun-god; and, in cloud half-seen,
Evanished into Delphi's thickets green."

A Young Practitioner.—It may, like chloroform, be administered on lint.

Dr. J. Miller.—The paper has been received.

USE OF LANOLINE IN MIDWIFERY PRACTICE.

To the Editor of THE LANCET.

SIR,—Permit me to call the attention of your readers to lanoline as a particularly efficient means of reducing the rigidity of the perineum in primiparæ. Owing to its penetrative and softening properties, I find it much preferable to the plan adopted by me of friction with pure lard. Only a few days ago this rigidity was strongly marked in an elderly primipara, where the forceps were required on account of debility on the part of the patient. I was surprised with what facility I succeeded in reducing it so as to enable me to apply the forceps much sooner than I should otherwise have felt justified in doing on account of the danger of severe laceration.

I am, Sir, yours truly,

Belford, Oct. 26th, 1886. C. CLARK BURMAN, L.R.C.P. & S. Edin.

VIPER POISON AND RABIES.

A WRITER in *Los Avisos* mentions that a dog which had been several times severely bitten by different rabid dogs, and had shown no symptoms of rabies itself, had been previously twice bitten by vipers, and suggests the possibility of the poison of the viper having conferred an immunity from rabies.

Mr. Spurgin.—We cannot understand why the judge refused to take the evidence of a scientific witness, as the case was pre-eminently one calling for decision on professional and technical grounds. We trust the matter will not be allowed to rest where it is, or a dangerous precedent will have been created. The honour of the profession, through one of its legally qualified representatives, is at stake.

THE letters of *Dr. Pirie* [illegible] and others must stand over till next week.

UNIVERSITIES' MISSION TO CENTRAL AFRICA.

FOR the last five years the above Mission has maintained a medical mission on the East Coast of Central Africa. As we are informed, the medical mission has done, and is doing, very effective work among the natives there. A fully qualified surgeon sent out by the Medical Guild of St. Luke is at the head of it; and, in addition to attending the European members of the Mission and the natives directly under its charge, he gives medical advice, attendance, and medicine to the natives in the surrounding districts. The Mission is rapidly gaining influence over them; but, in order to carry on the work effectually, a large stock of drugs and medical appliances is required, and the drug fund of the Mission is no longer sufficient to provide these articles in proper amount. An appeal is therefore made for subscriptions, which may be sent, marked "For the Drug Fund," to the Secretary of the Universities' Mission, 14, Delahay-street, Westminster.

Querens.—The duty of a regular practitioner who is asked to see a case, merely for diagnosis, which is being attended by a homœopath, and in the absence of the homœopath, is simple. He should decline to do so. We do not exist as a profession to gratify curiosity about the nature of disease. We exist to cure it, or at least to treat it. If we are not permitted to do this, or are asked merely to supplement and support a system of therapeutics in which we do not believe, we have no mission.

Subscriber.—The plain name, with "M.B." and "Surgeon," is best.

CHRONIC DYSENTERY.

To the Editor of THE LANCET.

SIR,—Could any of your readers suggest a remedy for chronic dysentery (muciform)? Astringents of every known description, Ipecacuanha, Dover's powder, and bael have all been tried in vain. It occurs in a young man, and has now lasted for nearly two years.

I am, Sir, yours obediently,

October, 1886. EUREKA.

Mr. J. Powell.—It would be invidious, as well as difficult, to specify in detail the claims and the blemishes of each candidate. A study of their addresses, in connexion with what can be learnt from the ordinary sources of information, will enable any practitioner to form a fair opinion for himself. Our correspondent has about a dozen or fifteen to choose from. He can only vote for three. The act of selection must be the act of each registered practitioner. We advocate freedom of choice and the preference of general practitioners. The Council is full of the consultant class and the representatives of corporations. Let us hear in the Council the views of men who have to do the hard work of the profession.

Mr. R. Fendick.—75, Park-street, Grosvenor-square, W.

TREATMENT OF OZÆNA.

To the Editor of THE LANCET.

SIR,—I should feel greatly obliged if any of your readers would give me some hints in regard to the treatment of an obstinate case of ozæna which remains from an attack of diphtheria some years ago, and which has hitherto defied all attempts at cure.—I am, Sir, yours faithfully,

Oct. 26th, 1886. SUBSCRIBER.

Mr. Owen Coleman would do well to communicate with the Secretary of the Medical Officers of Schools Society, Dr. Alder Smith, Christ's Hospital.

R. P.—Klein, Micro-organisms and Disease.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Buzzard, London; Dr. Harkin, Belfast; Mr. E. A. Barker, London; Dr. A. Duncan, Glasgow; Dr. Campbell, Alfreton; Dr. Savage, London; Dr. E. P. Thurstan, Southborough; Mr. Thomson, Glasgow; Dr. W. Dale, King's Lynn; Mr. Maynard, Newcastle-on-Tyne; Mr. Pugin Thornton, Canterbury; Mr. H. M. Jones, Liverpool; Dr. Markham Skerritt, Bristol; Mr. E. Cheshire, Birmingham; Dr. Granville Bantock, London; Mr. Robertson, Mexbro'; Mr. Cotterell, Bicester; Mr. J. J. The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Lectures
ON
DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

BY HENRY POWER, F.R.C.S.

LECTURE III.—PART I.

GENTLEMEN,—The disease of which I have to speak to-day is Abscess of the Lacrymal Sac—its symptoms, results, and treatment: a disease that has been so fully and so well described by Mackenzie that it is unnecessary to do more than mention its salient points.

Two forms of this affection may be recognised: one primary, arising suddenly and passing through its phases rapidly; the other secondary, consequent upon antecedent disease of the sac, and less violent in its character. In the primary and acute form of dacryocystitis the sac is suddenly attacked with violent inflammation, pain is felt at the inner angle of the eye in the region of the sac, which is tensive, throbbing, and severe. This part of the face becomes red and swollen, and the redness extends over the eyelids and cheek, and in bad cases to the mouth and nose, presenting in many instances an ill-defined margin and a general resemblance to erysipelas, for which it is sometimes mistaken, the affection of the sac being overlooked. There is a variable degree of conjunctivitis of a catarrhal character, attended with chemosis and purulent discharge, so that the lids are glued together, and the patient is temporarily and mechanically deprived of vision—a condition that may occasion considerable mental depression. This is greatly aggravated by the severe pain, which prevents sleep, takes away all appetite for food, and leads to the occurrence of well-marked constitutional symptoms, rapid pulse, debility, and even rigors. In the course of a week the skin near the inner canthus assumes a purplish hue, and if left to itself matter forms, points at this spot, and discharges itself through one or two small openings. Retrocession of the symptoms then rapidly takes place, the redness and swelling become day by day more and more circumscribed, and the patient is once more able to open the eyes; pain diminishes, and at length vanishes. At this period one of two things may occur. The discharge from the opening in the skin may become thinner and less abundant, till at last it is only a yellowish watery ichor, and healing takes place; or a larger patch of the skin may die, when a fistulous orifice is left, into which a probe may be passed and made to penetrate the lacrymal sac. The case then becomes one of lacrymal fistula. The position of the opening of the abscess, when spontaneous, varies greatly in different cases. In the great majority of cases (98 per cent. according to Velpeau) it bursts in front of the sac, at a point which corresponds, when all swelling has passed away, to the lower margin of the orbit, at the point where it is in contact with the lacrymal sac; but it may discharge at a much more distant point. Thus Velpeau saw one case which opened upon the cheek, and another where the aperture was nearer the ala of the nose, a sinuous passage more than an inch long extending in this case between the sac and the external opening. The abscess may, however, discharge itself internally, and not externally; various cases are on record where the matter has discharged itself through the internal wall of the sac into the nasal meatus, and through the outer bony wall into the maxillary sinus; and I have seen one case in which it made its way apparently between the periosteum and the bone, till at length it reached the floor of the nose and established a fistulous orifice into the mouth through the palatine suture of the palatal bones.

Lacrymal abscess is rarely a primary disease. It may, of course, proceed directly from injury and from exposure to cold, but in the great majority of cases there can be little doubt that it occurs in those who are predisposed to an inflammatory attack by antecedent chronic inflammation of the membranous sac and duct or of the surrounding bone. These conditions are known as dacryocysto-blennorrhœa and dacryocystitis-catarrhalis. In the former case the contents of the sac are comparatively clear and transparent, and consist of mucus and tears, with but little pus; whilst in the latter case they are composed chiefly of pus. Some difference of opinion exists as to whether the accumulation is greatest at night or in the early morning, but it is usually stated that the sac becomes in most cases clear and empty during the night owing to the slow drainage, and turgid during the day from the larger amount of secretion that is produced in consequence of the movements of the eye and reflex stimulation of the glands.

Considerable discussion, both written and oral, has taken place on the question whether stricture of the lacrymo-nasal duct is caused by inflammation, or whether it precedes and induces the inflammatory attack. This point is not easily settled either by anatomical research or by clinical observation. Mere congestion, which may be quite sufficient to swell the membrane and obstruct the passage of tears, leaves very slight traces after death; whilst, on the other hand, it is certain that constriction may long exist without occasioning inflammation of the sac in the absence of any exciting cause. It seems probable that in most instances some chronic inflammation affects the duct, interfering more or less completely with the flow of tears into the nose. Exposure to cold, a catarrh, or some other cause, then causes an acute inflammatory attack; pus is generated, and an abscess forms, which may burst externally or (rarely) internally. This view is supported by the circumstance noted by Abadie[1] and Naudier, that when any existing obstruction at the lower part of the canal is relieved and the calibre of the duct restored to its normal size, inflammation of the sac, though it may previously have been rebellious and recurrent, soon disappears.

Velpeau[2] has noted that the dominant idea of the numerous works proceeding from the great school of the Academy of Surgery in France, and the view adopted and supported by Scarpa in regard to the etiology of dacryocystitis and lacrymal fistula, was that they were the result of some mechanical obstacle to the course of the tears. Heister was amongst the first to notice that the causes of this disease were of an inflammatory nature rather than mere obliteration, and this was the view entertained by Hunter. After him Demours and the English school, headed by Mackenzie and Lawrence, combated Scarpa and nearly all the surgeons of the last century, maintaining that lacrymal tumour is, in reality, only one of the accidents of chronic inflammation of the lacrymal passages. This view is now generally accepted; and, as Velpeau shortly expresses it, in the beginning the disease is almost always a moderate or chronic inflammation of the mucous membrane, which may originate either in the conjunctiva or in the sac itself, or in the nasal passages, and may in course of time induce a swelling, or vegetations, or ulceration of the mucous membrane; the last condition being rare, and estimated by Demours at only 1 per cent. of all cases. When inflammation is once established, purulent or mucous exudation takes place, and gives to the fluid contained in the lacrymo-nasal passages a consistence which favours its retention in the sac, especially since the calibre of the duct is diminished.

The observations of Hunter[3] on the etiology of this disease, though brief, are worthy of consideration. Fistula lacrymalis, he says, arises from an obstruction taking place in the passage of the tears from the lacrymal sac into the nose. "The causes are often foreign to the nature of the parts themselves, as the small-pox or measles. This I suppose not to originate, as has been supposed, from a pustule at the end or mouth of the duct, but from inflammation running along the duct and causing the sides of it to adhere; it may also arise from ulceration of the duct from a venereal or scrofulous disposition in the part, but most frequently from obliteration of the canal from inflammation. The tears not passing, the inner surface of the sac becomes stimulated by pressure and distension, and the salts of the tears, which have little or no effect while the sac is natural, when diseased irritate it and produce inflammation. The sac swells, suppurates, and opens externally, and discharges the tears by this opening till the natural passage opens or a new one is made. If the os unguis had

[1] Journ. d'Ophth., April, 1872.
[2] Dict. [illegible], xvii., p. 378.
[3] Hunter, [illegible] edition.

been susceptible of the stimulus and had ulcerated, it would have been fortunate, but it only thickens to defend itself from the disease; for we find Nature has made internal parts less susceptible of such stimuli, the ulceration only taking place next the skin, so that it would, perhaps, be better for us if Nature would sometimes vary from her usual course. This internal thickening is sometimes so great as to unite the external part of the nose to the septum, and render the operation of perforating the os unguis less successful. Opening the old passage seldom succeeds, as it is very liable to become diseased again, as in strictures of the urethra, which are so apt to recur, and here bougies cannot be had recourse to occasionally, as in the urethra. The operation, however, should not be done precipitately, as the duct often clears of itself, and the patient gets well."

Amongst the predisposing causes of acute inflammation of the lacrymal sac, pregnancy appears to be one of the most common, perhaps on account of its depressing influence on some constitutions, and partly, too, from the confinement to one room and want of exercise, to the constipation which so often accompanies it, and to the general derangement of the health. It is not unfrequent during lactation, and Galezowski states that lacrymal troubles often supervene suddenly, owing to violent and spasmodic efforts made during delivery.

I have not the least doubt that obstruction of the naso-lacrymal duct terminating in abscess is frequently associated with a carious tooth, adding one more to the numerous ophthalmic affections that are associated with, if not directly attributable to, dental disease. The periostitic inflammation which exists at the root of the tooth either spreads over the surface of the bone, and so leads to thickening of the membrane covering the ascending lamella of the superior maxillary bone, or the inflammatory process at the root of the tooth may possibly extend through the bone itself. In either case the mucous membrane becomes reddened and chronically swollen and congested, and when it is remembered that the inferior orifice of the nasal duct in the membrane is often only a small slit or round hole, it is easy to understand that a comparatively small amount of swelling may lead to the complete obstruction of the passage and to the retention of the tears in the sac. The very position and form of the swelling show that the obstruction is situated at the lower orifice of the tube, and before the lacrymal abscess develops, not only may some epiphora exist, but the region of the tooth and the part of the upper jaw extending towards the nose may, by carefully applied pressure, be found to be tender. I saw a lady who illustrated these remarks exceedingly well. In her case the right upper canine tooth became carious, the eyes being perfectly healthy. Some months after the tooth was affected she noticed that her right eye had become "watery." Whilst she remained at rest in a warm room no overflow of tears occurred, but exposure to cold air immediately compelled her to have recourse to her handkerchief for this eye. For a long time she had little pain in the tooth, though the caries was gradually extending through its substance. At length and suddenly, without apparent or known cause, lacrymal abscess formed, and, after causing considerable erysipelatous inflammation of the cheek, burst through the canaliculi, through which, when the inflammation had subsided, matter could for some time be squeezed when gentle pressure was applied over the region of the sac. The sequence of events seems here to be tolerably clear. The carious tooth caused periostitis, which at first obstructed and then caused complete closure of the inferior orifice of the nasal duct. Suppuration of the lining membrane was then occasioned by some cause, such as the action of cold or the entrance of some pathogenic germ, and the tube being elsewhere pervious, the purulent contents of the sac were discharged through the canaliculi. I can imagine no better evidence of the action of a diseased tooth in the production of lacrymal obstruction and abscess. I do not wish to insist too strongly on this connexion, but I think that in all cases of obstructed duct, where no cause is immediately recognisable, it is expedient that the teeth should be examined, and, if found diseased, that the patient should be placed under the care of a competent dentist. In many cases probably extraction would be the safest plan, but on this point I am not able to express a confident opinion. If the abscess be allowed to burst spontaneously, and even in some cases opened *secundum artem*, the aperture by which the pus has escaped remains patent, and a fistula lacrymalis [illegible]

Congenital fistula of the lacrymal sac has occasionally been noticed. Thus Steinheim[4] describes a fistula of the duct opening upon the surface of the upper lid, and believed to have existed at birth. Tarson[5] reports two cases of the sac, but whether congenital or not is uncertain. Manz[6] writes: "It is still doubtful whether a congenital fistula of the lacrymal sac has been observed, though the possibility of its appearance as an occasional failure of the nasal duct to close is not to be denied." In this case it should be viewed as an arrest of development. Whelock Rider[7] has recorded what appears to be an indisputable case. The patient was twenty-one years of age, and presented about half an inch below the inner canthus and over the course of the lacrymal sac the opening of a canal sufficiently large to admit for a short distance upward and inward a No. 8 Bowman's probe, but it could not be made to enter the sac. The integuments about the opening and the walls of the canal were slightly indurated. Efforts at expiration with closed nostrils caused some clear fluid to exude. The fistula was noticed when the patient was only a few days old.

ABSTRACT OF THE

Introductory Lecture

Delivered at the opening of the Winter Session of

ANDERSON'S COLLEGE, GLASGOW,

By J. R. WOLFE, M.D., F.R.C.S.E.,

SURGEON TO THE OPHTHALMIC INSTITUTION, AND LECTURER TO THE COLLEGE.

AT the outset the lecturer referred to the great advances recently made in medicine and surgery, as exemplified in the discovery of new drugs and in the operations now performed on several parts of the body which were formerly deemed to be beyond the reach of the surgeon. He thus showed that students now entering on their medical studies enjoyed many and important advantages which could not be offered to their predecessors. In this way the pleasure of the study had been considerably enhanced, but at the same time the responsibilities laid on students had become much heavier. Amidst the crowd of practitioners at present no one could push his way to the front by simply repeating other people's formulæ; it could only be done by independent thought and indefatigable industry. Dr. Wolfe then proceeded as follows:—

"The department of surgery which is my own province has made rapid strides since the discovery of the ophthalmoscope by Helmholtz. Previous to that discovery nearly all was guess-work, but by that instrument we have revealed to us all the deep tissues of the eye, the very commencement of an affection of the retina, optic nerve, vitreous and choroid, and even diseases which may exist in the more distant parts of the organism, such as the brain, heart, lungs, and kidneys, as well as constitutional cachexia. The discovery gave such an impetus to the study of eye diseases and to the development of eye surgery, that, thanks to the numerous labourers in that department in different parts of the world, ophthalmology may now be said to have approached the nature of an exact science.

"Among the eminent men of our profession who flourished in France during the Second Empire, such as Nélaton, Trousseau, Velpeau, Claude Bernard, &c., whose labours I have reported in THE LANCET of that period, no one deserves greater credit than Desmarres. By his brilliancy of conception and dexterity of execution he may be said to have revolutionised ophthalmic surgery. He was the first to show us how great is the liberty which may be taken with all the tissues of the eye, provided they be properly manipulated. He not only gained great victories over disease himself, but laid the foundation for future progress. The one eminent disciple of Desmarres who was destined to gain world-wide renown in ophthalmology was Albrecht

v. Graefe. Fired with the enthusiasm of Desmarres' teaching, he subsequently established an ophthalmic clinique in Berlin and became the founder of the ophthalmological school of Germany. When visiting La Charité in Berlin the other day, I saw with no small degree of pride the monument which has been erected to v. Graefe. This is the first public monument erected in that city to a private person, all others being in honour of royal personages and generals or other public functionaries. The distinction confers equal honour on the memory of our eminent *confrère* and on the Government of the German Empire. It shows that the old spirit of the nation —love of culture, appreciation of professional merit, and interest in all that benefits mankind—is still alive and has not been deadened by love of military glory. Herein lies the pledge of the future stability and prosperity of the nation. The statue itself is a beautiful life-like image of the man, but I could not help thinking that a lancet used in iridectomy, by the introduction of which operation he conferred a great boon on many sufferers, would have been more appropriate in his hand than an ophthalmoscope, an instrument invented by Helmholtz; nor could I help feeling that the symbolic group on each side of the statue was so paltry and insipid as only to disfigure the monument. Graefe was peculiarly fortunate in living during what may be called 'the golden age' of ophthalmology. There was such an absence of professional and national jealousy that he obtained the support, not only of the whole of the medical profession of Germany—without which, he himself said to me, he could never have tested the efficacy of his cure of glaucoma by iridectomy,—but also that of the Vienna, French, and other foreign schools. One great service which he rendered to this department was the founding of the *Archiv für Ophthalmologie* in conjunction with Arlt and Donders, the latter of whom published in this journal his famous papers on Refraction and Accommodation of the Eye, which now forms the canonical book of oculistic surgery. I, however, think it very unfortunate that Graefe's last work has not proved a success. I refer to his method of extracting cataract. At the meeting of the International Ophthalmological Congress at Paris in 1867, at which the operation was discussed, a report on the results of the new method was read by Otto Becker, then of the Vienna school. It was violently attacked by Professor Hasner of Prague in the *Annales d'Oculistiques*. I objected to it at the time as positively bristling with dangers. Notwithstanding the unfavourable report of the Vienna surgeons, which I deemed conclusive against it, it is still practised, and human eyes have been sacrificed in great numbers, both in this and other countries. In the old operation we never heard of sympathetic inflammation of the other eye, but in connexion with Graefe's cases came under my own observation in which the eye operated on has had to be removed and the other has become inflamed. It is very curious that in the most recent apologies for failure the micro-organisms are held to be responsible—the poor bacteria have to bear the whole blame. I regard this operation as calculated to tarnish the fair fame of v. Graefe, as the two groups are a disfigurement to his statue, and I therefore hold that it ought to be excluded from ophthalmic practice. I speak strongly on this subject because I know the misery which is caused to families by such disasters.

"When I was asked to address you to-day on ophthalmic medicine and surgery, I thought that it would prove useful to you that I should explain the general principle which underlies some operations which I have introduced, and the way in which they have been worked out by me. In searching for the safest and best method of operating for cataract, I have, during every stage of the operation, studied all the possible sources of danger and the surest means of eliminating these dangers, and have thus endeavoured to meet every possible contingency. I have in this way arrived at a method which is absolutely safe—so safe, indeed, that one need hardly ever fear of failure. In twenty cases on which I operated in the course of one month in the presence of four of my colleagues, there was not a single hitch during the operation or in the subsequent treatment; vision restored in all. Some of the cases operated on by me during the present month have been very critical. One patient, seventy-two years of age, was discovered to have heart disease; another had bronchitis and asthma to such a degree as to disturb the other patients; while in a third the cataract was the result of an injury of thirty-four years' standing, and in addition to traumatic complications there was a pterygium covering a great part of the cornea. I have also recently operated upon one of our citizens at the advanced age of ninety-one. In all these cases the healing process went on without a single complaint of pain in the eye, and vision was restored. I may mention that the risk in old people lies in the tendency the cornea has to collapse, and in consequence of that collapse there is a difficulty of removing the whole lens and a probability of subsequent suppuration. But these are simply facts which must be present to the mind of the operator, and according to which he must regulate his incision. It was only by carefully observing how Nature herself cures wounds and injuries that I arrived at a sure method of conducting this operation.

"The operation for the formation of new eyelids from skin flaps taken from distant parts was first suggested to me by the procedure of M. Reverdin, who grafted small bits of cuticle for the cure of ulcers, and the results obtained were tolerably good. I found, however, that when applied to the face this method gave it a scurvy look, and I was obliged to try the transplantation of a large flap, endeavouring to cut the cutis merely and keep free of cellular tissue. The fact that about one-third of a flap so cut suppurated proved to me that, though the first part could easily be cut free of cellular tissue, the knife is apt to go deeper when cutting is continued further. Hence, I concluded that if we want a large flap of skin to heal by agglutination, we must first remove it and then pare off any cellular tissue there may be underneath. Though on the publication of my first success the operation met with no favourable reception, it is now generally adopted. Of all the satisfactory reports of its success there is none more so than that by Dr. Swanzy of Dublin, who operated in seven cases. He reports that 'it was not until forced by the circumstances of a case that he employed it; now, having found it a most satisfactory proceeding, he much regrets that he postponed its trial so long.' To the practice of skin transplantation I was led by a feeling of sheer desperation. 'Here,' I said to myself, 'is an eye which might be made a useful organ but must be allowed to waste for want of a flap of skin which cannot be taken from the neighbouring part.' I was then compelled to study how the want could be supplied. This is also true of transplantation of conjunctiva from the rabbit.

"By the same feeling I was led to practise another operation—viz., that for detachment of the retina. If surgeons could remove dropsical fluid from the abdomen and thorax, were oculists to be baffled and pronounce a case incurable on account of retinal dropsy? It is true we have delicate ground to work upon, but this only shows the great necessity there is of taking advantage of all the devices of our art and devise new plans in order to overcome the difficulty. For what is ophthalmic surgery but simply the performing, in a delicate and precise manner, of operations upon the tissues of the eye which can be done on a large area in any other region of the body? My first successful case, reported in THE LANCET in 1868, was total blindness in both eyes; but such cases are not very numerous, and the operation had consequently a hard struggle to come to the front—in fact, six years elapsed before I had an opportunity of again bringing it prominently before the profession. This case, which had been certified by surgeons of another hospital as one of detachment of the retina, was exhibited before the Glasgow Medico-Chirurgical Society and the British Medical Association at Belfast in 1884. But all surgeons who had tried the operation in this country had invariably failed, and consequently more convincing proof was still required. This was afforded me in the end of the same year, when I was invited by two Parisian oculists to give a demonstration of my method on patients provided by them. I did so, and with success. The demonstration was reported in several medical journals in France and in this country. By its success great impetus has been given to the operation, and surgeons have been encouraged to study it more carefully than they have hitherto done.

"With these explanations you will be able to appreciate some of our endeavours to extend the sphere of eye-surgery, and to bring within the province of operative interference certain groups of cases which have until recently been considered incurable. Nor are the resources of surgery yet exhausted."

Dr. Wolfe, in conclusion, referred to the arrangements which have been made for the removal of Anderson's Medical School to the neighbourhood of the Western Infirmary.

ABSTRACT OF

Introductory Address

ON THE

SOCIAL, SCIENTIFIC, AND POLITICAL INFLUENCE OF THE MEDICAL PROFESSION IN THE YEAR 1886.

Delivered on Monday, November 1st, 1886,

BY L. HEPENSTAL ORMSBY, F.R.C.S.,

SURGEON TO THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

GENTLEMEN,—On such occasions as this it is usual for the lecturer, in opening the session, to select some topic of passing interest wherewith to engage your attention for a very long hour or fifty minutes. At the risk of pleasing some only of my hearers, I select for my address the following subject—"The Social, Scientific, and Political Position and Influence of the Medical Profession in the year 1886." The topic no doubt is a large one, and embraces a wide field; however, in my allusions I will be as brief as the subject will admit.

The social position of the profession may best be viewed as regards the different countries and services we meet with in its members. First, as regards Ireland, the country most interesting to us all. In the past the metropolitan physician and surgeon was generally a man sprung from the ranks of aristocracy, and highly educated. Now, however, we find all grades of society entering the profession if they have the inclination and means to enter it. No one is debarred. All have the same chance to win their way to position and affluence. As there are degrees in trade, law, the public services, and other lines of life, so are there degrees of social standing in medicine and surgery. For in trade any ordinary individual can understand the difference between the social position of the prince merchant and that of the small huckster, and yet both belong to the same calling. In the great profession of law we have the same degree of social standing. We have the Lord Chancellor at the top of the social system, and the respectable legal practitioner who practises in the Lord Mayor's Court, and yet they both belong to law. Throughout the country our profession occupies as good a position as any other. There is no doubt that many depreciating influences are at work to more or less vulgarise the medical profession and its members. We have to contend against the great influx of very low persons, who now enter the profession without birth or refined feeling enough to realise the utter shipwreck they make of their calling if not suited to practise it as it ought to be practised. Again, there has not been, up to the present, any uniform State-qualifying examination through which all must pass before entering the profession in the three kingdoms. There have been at least twenty or even more portals, so that each licensing body, in order to attract or encourage men to enter it, offers, or pretends to offer, some special advantage. In this way many very badly prepared and half-educated men get their names on the Register year after year. Moreover, so long as you have a profession or licensing body allowing its members to adopt the low scale of fees beginning at sixpence for advice, consultation, and medicine included, what can you expect but a downward course of appreciation on the part of the general public? I firmly believe the system of low fees charged by general practitioners for drugs and medicines alone—in fact, for the mere mechanical agents of treatment, and not for the exercise of brains and judgment which select them, called advice—has done more to produce professional demoralisation in the rank and file of our order in England and Scotland than anything else, and has been the cause of the low place those who follow the practice are asked to occupy in the social system of modern society. Another depreciating influence which the Bar certainly does not suffer from, but which we do, is that the medical profession is not necessarily metropolitan, which the Bar certainly is; for in the remotest corner of the country we must necessarily find the medical man practising among people who, socially [illegible] scientifically, are very inferior to him in their attainments, and who are unable to offer him any advantages in his social intercourse; and in this way he loses tone in his conversation, in his dress, in his manners, and in his influence, and occasionally he contracts habits which certainly cannot be commended. There is another depreciating influence we must fight against until the general masses are properly educated so as to understand correctly and clearly the grades and social position the profession and its members ought to occupy. This depreciating influence is the absence of suitable State recognition for the leaders of medicine and surgery. In the constitution of our governmental system there should be (and it is imperatively called for) the Minister of Health or Sanitary Science, who should occupy a seat in the Cabinet, and to be only filled by a physician or surgeon of eminence and ability.

I must now dwell for a few moments on the second part of my theme—the scientific influence and position of the profession in the present day, and I would say to no class does science owe so much. Medical men from the days of Hippocrates have all along the line been the pioneers and promulgators of science. Contemplate for one moment their incessant toil, the varied, intricate, and in some cases most dangerous investigations in the cause of scientific truth, the combined result of all being that the community at large have alone derived the advantage of their labours. What has the discipline of law, divinity, or arms, as a body, done for science? Think of the enormous debt of gratitude that ought to be bestowed on medicine and surgery; and this fact can never be told too often, when the ignorant, the ungrateful outsider attempts to depreciate and minimise the labours of the profession. Although the public occasionally are slow to appreciate our scientific labours, we have an institution that we may well be proud of, and one which has helped to make England famous in the scientific world. I allude to the Royal Society of London, which knows no creed, no politics, no social class. Its object is pure and untarnished, as it was simply established for the furtherance of truth and science and for the recognition of original scientific work. The humble, and it may be unknown, worker will surely find his investigations carefully weighed and duly acknowledged by the conferring of the blue ribbon of science (the fellowship of the Royal Society), a reward far greater and perhaps more to be desired than the highest honour the State can bestow; and I am delighted to say that being an Irishman is no bar to its distribution, and physicians and surgeons have more frequently been the recipients of this much-coveted and enviable distinction than any other of the learned professions.

I must now say a few words as regards the political influence of the profession in the present day. Ten years ago, when I addressed you, there were but four medical men in the House of Commons, now there are ten; but even this increase is by no means a sufficient representation of their wants and wishes. The question arises, however, How can a man afford to give up his practice and lose so much a year for the cause of the public at large? and such self-denial is, to say the least of it, rare. If medical corporations wish to have medical representatives who are in touch with their present wants and aspirations, they must pay their representatives so much a year to make it worth their while to remain in Parliament and represent their views. Few medical men are able to put together large fortunes until they are advanced in life. At first, no doubt, there may be some little difficulty or jealousy in the selection, but the right man will turn up in the right place; and it is to be hoped that he will be a man who is thoroughly in accord with the wants of the great profession, and, having engaged in the practice of it, be better able to understand what will most conduce to its best interests. The man to represent the profession should be a comparatively young man, for this is the age for young and vigorous men. The University of Dublin and many of the other educational bodies must be represented by medical men if medical science is to have a place in the Legislature, and if we are not satisfied to allow the rank and file of the profession, numbering nearly 30,000 members, to remain silent.

And now let me for a moment invite attention to the position of our brethren in the army. Ten years ago, gentlemen, I warned you against entering the Army Medical Service, as I compared it then to a series of dissolving views of which we were at that time, in an interval, waiting for the next picture. I told you the remedy was simple, for if

the gentlemen who had an ambition to serve their Queen and country would only hold back for a short time, they would compel the authorities to rectify the glaring and iniquitous defects by placing the army medical officer in his proper position, and giving him, in all fairness, equal advantages with his less scientifically educated combatant brother officer. I am happy to say my advice was taken, and the authorities were compelled, for want of men, to remedy many defects, but not all, as some few still remain. The army surgeon has a grievance which should be at once remedied. It appears that the commissions of those for the Indian Medical Service are dated from the period of joining Netley, while those for the Army Medical Department bear the date on which the course of instruction closes. The practical result of this difference is, that the Indian medical officers become the seniors of the others by four months, and this seniority must continue throughout their career, at least till they reach the administrative ranks. Formerly the rate of dating from the period of joining at Netley applied to both services, but the change was effected by the Warrant of 1877, *for reasons which have never been explained.* Furthermore, I feel a great injustice is frequently done to our army medical officers, who serve in unhealthy climates looking after the lives and health of the brave soldiers committed to their care. They may never have the luck to be in an engagement, and because they do not happen to see or hear a shot fired they are never decorated. Surely this is not fair or reasonable. Take, for example, the enormous and exhaustive duties of the chief administrative army medical officer in charge of a base hospital at some distance from active hostilities. No one who is not conversant with the minute details of his duties can really understand the wear and tear of mind and body such an officer endures, and yet this officer never gets any credit; his work is perhaps not known, and his name never appears in despatches. I would have all this changed. I would propose, if the military authorities do not do their duty to their medical officers, the corporations and licensing bodies from whom the medical officers have derived their diplomas should, from time to time, confer honorary high degrees on such as have proved themselves deserving of such distinction. In this way the decoration would be of more value, for it would be awarded by competent judges, who can distinguish high professional service on the part of the army medical officer, not perhaps on the battle-field, but in the prevention, cure, or alleviation of disease in outbreaks of fever, cholera, and other fatal disorders.

And now, in conclusion, I wish to say a few words to my junior hearers. Many of you are young men fresh from the country, with buoyancy of spirits, and without much ballast to freight you over the giddy whirlpools of a residence in town; and let me instil into you the fact that your early student life offers the best criterion we have of what your future professional life will be. All present, I am sure, wish to succeed, and you would like me to tell you how success is to be attained. Of one thing I am convinced, and that is that no such word as *impossible* should find a place in your vocabulary. A young man, I feel certain, can be very much what he pleases. You are now at that period of life in which you must turn to the right or left. You must now give proofs of principle, honesty of purpose, determination, and strength of mind, or you must sink into idleness and acquire the habits and character of a desultory ineffective creature, and if you once fall into that condition you will find it no easy matter to rise again. Pursue unflinchingly a course of irreproachable truth and rectitude, and you need fear nothing—not even the most sharp and cunning shafts that others, jealous of your progress, may choose to aim at you. The self-approval of your own conscience will be always to your own heart an infallible antidote against their poison.

JUBILEE OF A RUSSIAN MEDICAL PUBLISHER.—The *Zeitung für Buchhandel* states that the well-known St. Petersburg medical publisher, Carl Ricker, will reach his twenty-five years' jubilee in December. The Russian medical public is deeply indebted to M. Ricker for his enterprise in publishing a large number of national medical works and periodicals, amongst which latter the *Vrach*, which may be looked upon as the Russian LANCET, stands foremost. A multitude of translations of German, French, and English medical works have also issued in a Russian garb from M. Ricker's establishment on the Nevski Prospect.

TREATMENT OF UTERINE FIBRO-MYOMA.

BY J. KNOWSLEY THORNTON, M.B., C.M.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

(*Concluded from page 813.*)

THE third case is another illustration of the impossibility of diagnosing between some uterine fibro-cysts and ovarian cysts; and it also illustrates how success may be obtained in complete supra-vaginal hysterectomy by Schroeder's method of suturing the stump, when it is impossible to secure it in Koeberlé's serre-nœud outside the peritoneum—the plan I much prefer in the majority of cases.

CASE 3.—C. C. M——, aged thirty-nine, married eighteen years, and mother of one child aged seventeen, was admitted into the Samaritan Hospital, under my care, on April 12th, 1886, said to be suffering from an ovarian tumour. She was very anæmic and emaciated. There was a large globular cyst filling the whole abdomen, and percussion was clear in the flanks and epigastrium. On vaginal examination the uterus was found to be much enlarged, and displaced to the left side of the pelvis. I could not make out whether a large solid mass which nearly blocked the pelvis was part of the tumour or was a fibro-myoma, but I came to the conclusion that there was an ovarian cyst, and multiple fibro-myomata as well. The family history was good, but one of her sisters was known to have a fibro-myoma uteri. Menstruation was free and regular; occasionally she had an unusually heavy discharge. The kidneys were irritable, and secreted only about twenty ounces of pale urine, of low specific gravity and with a trace of albumen. The bowels were loose and irritable. She first noticed a hard tender lump in the left iliac region about four years ago. It had grown slowly till the last six months, during which the increase had been very rapid, with much pain in the back and under the ribs, and with very marked emaciation. I operated upon April 14th, and on opening the abdomen found a thin liver-coloured cyst, with recent adhesions all over its anterior surface, and dark contents, with much old blood clot. It had all the appearances of an ovarian cyst with a twisted pedicle. After emptying the cyst and separating the parietal adhesions, I found what I believed to be a false pedicle attaching it to the fundus of the uterus; but on transfixing and tying it, I found bleeding going on from the uterine surface below my ligatures from a crack, which at once suggested to me that the cyst was of uterine origin; and, proceeding farther to explore the pelvis, I found a large pedunculated subperitoneal outgrowth, to the pedicle of which the cyst was also adherent, and very free hæmorrhage occurred when I separated it. The uterus was, as I had expected, greatly enlarged by a mass of more or less pedunculate outgrowths, which surrounded it and extended deeply into both broad ligaments. Seeing that its removal would be unusually dangerous and difficult, I attempted to stop the hæmorrhage from the two torn uterine surfaces by suture, by actual cautery, &c., but found, as in similar cases before, that nothing would stop it, the uterine tissue tearing or cracking away and fresh bleeding taking place at each attempt. I therefore determined to perform a complete supra-vaginal hysterectomy, and having with much difficulty (owing to the growths in the broad ligament) tied off and removed the ovaries and tubes, I applied the serre-nœud to the uterus, but was obliged to put it on so deeply in the pelvis, that I found it would be impossible to bring it outside the peritoneum, and having before met with disaster from attempting a half extra-peritoneal and half intra-peritoneal treatment of the stump in a similar case, I decided to remove the serre-nœud, clean out the uterine canal right through into the vagina with corrosive sublimate and powdered iodoform, and then suture the stump on Schroeder's plan and drop it in. Having completed the operation, I placed two glass tubes in the pelvis, each with their separate rubber sheet and sponges. The temperature rose in the evening to 101°, and the pulse to 112. The tubes were removed at the evening dressing on the next day and the patient made an uninterrupted recovery, her temperature being normal and pulse 76 on the fourth day. On the seventh day after operation the sutures were removed and the wound was found well healed; at the same time I removed a plug of iodoform gauze which I had placed in the vagina after the operation. The bowels were relieved by enema on the eighth

day. The only trouble she had was from some return of the diarrhœa from about the twelfth to the fifteenth day; this was, however, easily controlled by a bismuth mixture.

I think it would be difficult to find a group of more instructive cases in the whole of my case-books, and yet they all come together, as so often happens in practice. The lessons which we learn from them are:—1. That there are certain ovarian cysts which, from their method of growth and from the way in which they stretch out the uterus and bladder as they grow, it is impossible to differentiate from uterine tumours. 2. That there are some fibro-cysts of the uterus which, especially when they are complicated with solid outgrowths, as they often are, it is impossible to differentiate from ovarian cysts. 3. That there are pedunculate fibro-myomata which grow so fast, and cause such emaciation, that it is impossible to differentiate them from solid ovarian sarcomata. 4. That the ovarian cysts which burrow deeply in the cellular tissue round the uterus are slow and uncertain in their growth, are often causes of considerable pain and distress, are apt to give rise to inflammatory action, which, if allowed to recur from time to time, renders their removal extremely difficult, and from their seat are especially liable to interfere with the action of the kidneys, and lead to serious inflammatory or cystic changes in these organs. 5. That in view of the impossibility of exact diagnosis in some cases, an exploratory operation should be advised whenever there is danger of interference with the ureters by intra-pelvic pressure, whenever the presence of the tumour gives rise to recurrent attacks of pelvic inflammation, and whenever other symptoms indicate operation. 6. That the operator who undertakes to perform ovariotomy must be prepared to find himself face to face with the most formidable hysterectomy which it is possible to perform, and therefore no one should undertake these operations without being fully provided with the appliances necessary for the completion of such exceptional cases.

Before concluding I must say a few words on the general surgical treatment of uterine fibro-myomata. I have at various times published in tabular form the results of my practice, and to these papers I will refer those who wish to go fully into the question.[1] I can only briefly here indicate the class of cases in which I would advise removal of the ovaries and tubes, and that in which I would perform complete supra-vaginal hysterectomy. Here I will repeat again what I have often said before, and what I always say distinctly to any patient upon whom I am to operate for fibro-myoma: "I propose in this case to remove the ovaries and tubes, because I think that is the most suitable and least dangerous operation; but I cannot pledge myself not to remove the tumour, because when the abdomen is opened I may find it impossible to remove the ovaries and tubes, or in a case in which I have intended to perform hysterectomy I may find it safer and better merely to remove the ovaries and tubes." In certain cases the removal of the ovaries and tubes is easy, and then it is a much less dangerous operation than hysterectomy. In certain other cases it is quite impossible to remove them without making a clean sweep of the uterus down to somewhere near the internal os. Again, in some cases it is so easy to include both broad ligaments in the same wire which surrounds the uterus, that it is an easier and safer operation to perform complete hysterectomy than merely to remove the ovaries and tubes. It is well to decide as nearly as one can before operating which operation is the right one in any given case; but one must always be prepared to modify that operation when the parts are actually before one's eyes and in one's hands. Speaking generally, small soft tumours or general enlargements of the uterine body, which cause hæmorrhage or pain or both, out of all proportion to their size, are those for which the removal of the ovaries and tubes can be best performed, and in which this procedure gives the most satisfactory results, and they are often very unsuitable cases for hysterectomy, because their bases are deeply seated in the broad ligaments, and their small size has not led to any stretching of the cervix, so as to bring the part where the serre-nœud should be applied up into the abdomen. As a general rule, the smaller the tumour the easier the operation; but it is not always so, as the fibro-myoma may grow out into one broad ligament, stretching the ovary and tube over its surface, so as to make it very difficult or even impossible to remove them efficiently and safely. Then there are certain comparatively small growths which involve the whole body of the uterus or the whole of one wall, carrying up the broad ligaments and ovaries and lengthening the cervix, which give rise to very serious hæmorrhage, and often grow fast. These cases are most suitable for complete hysterectomy, because this procedure is in them easy and simple, while it is often almost impossible to tie off the greatly enlarged and stretched ovaries. Then, again, there are certain cases in which the ovaries and tubes have become adherent in the pelvis, where it is very difficult to remove them at all, and still more difficult to make sure that they are thoroughly removed, and yet this may be the only possible procedure from the bedding of the fibro-myomata deep in the broad ligaments, and the density of the adhesions they have contracted there during the inflammatory attacks which have also glued down the ovaries and tubes. Then in certain cases in which the uterine mass has already become too large to hope for cure by oöphorectomy, the base will be too broad for the ovaries and tubes to be included in the wire, and they must be carefully ligated off before the wire is applied to the uterus, and when this is the case it is strongly advisable to pass the free end of the wire through the broad ligament on each side at the angle where it has been cut down in separating the ovary and tube; this not only affords a safeguard against bleeding, but it gives the wire a fixed point on each side, and when tightening it one is not nearly so liable to get it on to the bladder, or too deep towards the ureters—accidents which may easily happen if it can slide up and down the uterus. In a certain number of cases, and very formidable cases they are, it is not only necessary to ligate off the appendages separately, but also to divide the peritoneal covering of the uterus and peel back the bladder, or enucleate large masses of the tumour from deep in the broad ligaments, before the neck of the uterus can be cleared for the application of the wire. Such cases may require suture of broad ligament surfaces to one another or of peritoneal edges, or application of cautery or perchloride of iron, or drainage of cavities left in the broad ligament, but each must be dealt with as seems best at the moment, and I would advise those who have any doubt as to their fertility of resource and quickness of decision and execution in face of alarming hæmorrhage, to avoid meddling with uterine tumours, because the simplest operation may end in the most desperate difficulties. In saying this, however, do not let me be misunderstood: these dangers must be faced by some among us, for the time has come when fibro-myomata must be removed or kill in a certain number of cases, and it is no use for those who will not see the necessity to din into our ears the old cries that they do not kill, and that therefore they must be left alone. They do actually kill in a large number of cases, by hæmorrhage, by peritonitis, by slow invalidism, and by destruction of the kidneys. Probably if we could get at the true life-history of all the cases of uterine tumour, we should find a very heavy death-rate from granular kidneys and their results—heavier far than anything surgery has to mourn in its tentative march towards a radical and fairly safe operative cure.

I opened my remarks by pointing out how we may in many cases spare the knife by judicious treatment. I will close them by saying that I have attacked eighty-eight cases of fibro-myoma or fibro-cyst of the uterus, with a mortality of 15·9 per cent., much of which is due not really to surgery, but to diseases which have resulted from pressure, from inflammation, and from exhausting hæmorrhage, before the aid of surgery was invoked. Eleven of the deaths occurred in the first half of the cases, and only three in the second half. And who can say that this mortality, among the most miserable and most diseased of the cases, is not amply atoned for by the seventy-four healthy and useful women who enjoy again new lives as the result of operation?

ON SOME CASES OF CYCLOPLEGIA, OR FAILURE OF THE ACCOMMODATION.

By W. J. COLLINS, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng.,
OPHTHALMIC SURGEON TO THE NORTH-WEST LONDON HOSPITAL, AND TO THE WESTERN OPHTHALMIC HOSPITAL.

THE intrinsic muscles of the eye not unfrequently suffer from various degrees of paralysis, paresis, or atony. Six well-recognised varieties of such palsy exist—viz., (1) Paralysis of all three intra-ocular muscles, the dilator and sphincter pupillæ, and the ciliary muscle, the iris being motionless and accommodation impossible—so-called ophthalmoplegia interna;[1] (2) paralysis of the sphincter pupillæ alone—paralytic mydriasis; (3) paralysis of the dilator pupillæ alone—paralytic myosis; (4) paralysis of the ciliary muscle alone—cycloplegia; (5) paralysis of the sphincter pupillæ and ciliary muscle, as commonly occurs in oculo-motor palsy; (6) paralysis of both muscles of the iris, or iridoplegia. It is questionable whether the only other possible combination of paralytic myosis and cycloplegia ever occurs, and the innervation of the muscles would not suggest the likelihood of such coexistence.

Each of these various palsies may be either complete or of various degrees of incompleteness. Their causation may be classified under the three heads—(1) toxic, local or general; (2) traumatic; (3) pathological. Under the first heading would be included the familiar effects of atropine, homatropine, anæsthetics in the late stage; also duboisine, daturine, hyoscyamine, gelsemine, muscarine, and coniine.[2] In the second category would be placed the various effects of contusion on the irido-ciliary system; iridoplegia and mydriasis are perhaps the most common. I have known the former persist for weeks, months, and even years after the injury; failure of accommodation from this cause is, I think, less common, and when present less pronounced. It is to a particular group of the cases which fall under the third heading that I wish to direct the attention which I think they have not sufficiently received.

Now, failure of accommodation may, of course, be due to inability of the eye to effect either or both of the requirements upon which this action depends—viz., (1) slackening of the capsule by contraction of the radial fibres of the ciliary muscles, and (2) the increased thickness of the lens by virtue of its elasticity. An example of the failure of the latter preventing accommodation is seen in the early stages of cataract; its cause is mechanical, and it has nothing in common with the nervous and muscular causes of cycloplegia. Again, the regularly progressive restriction of accommodation from youth to age can hardly be deemed other than physiological, and only attracts attention and demands correction when the near point has receded further than the vocation of the individual requires. The advancing presbyopia of glaucoma is usually ascribed to the deleterious effects of tension upon the ciliary nerves and their branches.[3] Next, there is a whole group of diseases or morbid states which are perhaps the most frequent antecedents of that asthenopia which results from atony or paresis of the ciliary muscle—diseases which have this one characteristic in common, that they are debilitating diseases, and produce marked and persistent anæmia, accompanied by languor and a general depression of the nervous and muscular systems. Foremost among these stands diphtheria, the facts concerning which were worked out by Trousseau[4] and Donders,[5] typhus,[6] small-pox,[7] typhoid,[8] gastric fever,[7] rheumatism,[6] diabetes,[9] trichinosis,[6] locomotor ataxy,[6] and forms of sore-throat of a non-diphtheritic character.[8] In 1871 Mr. Hutchinson[3] pointed out that during lactation accommodation may fail, and I have numerous notes of cases in which the amplitude of accommodation has been reduced many dioptres, and this usually in proportion to the protraction of the nursing and the inability of the mother to meet the additional demand upon her strength. I have also observed similar cycloparesis during pregnancy, in the puerperal state, after abortion and miscarriage, and associated with menorrhagia and dysmenorrhœa. A few of these cases I may here cite in detail.

CASE 1.—Mary E——, aged twenty-nine. Married nine years; six children, last three months ago, suckling. Complains of "stabbing pains in the eyes" and "dimness" since confinement. She shuns the light, constantly wipes the eyes, and resents examination. The eyes appear perfectly normal, but while V = $\frac{6}{12}$ with + 1 D, she cannot read Jaeger 1 or 2 at any distance, but with +3 D she can do so easily. With −3 D cannot see even $\frac{6}{60}$. She is delicate and anæmic. Ordered a mixture of citrate of iron and ammonia, and to begin to wean the child. One month later she could read Jaeger 1 fluently at 22 cm., and all asthenopia had disappeared.

CASE 2.—Susan F——, aged twenty-eight; three children, last ten months old; suckling. Complains of asthenopia; cannot read or sew close to her. V with each eye $\frac{6}{9}$; has ·5 D hypermetropia. With +2 or +3 D reads Jaeger 1. Cannot neutralise even a - 3 D glass.

CASE 3.—A. R——, aged thirty-two. Multipara; aborted nine months ago at three months of pregnancy; since then has been delicate, and suffered from asthenopia. V with each eye = $\frac{6}{9}$; cannot read small print or sew. With +3 D reads Jaeger 1. Cannot see $\frac{6}{60}$ through −3 D.

CASE 4.—S. B——, aged forty. Seven children, last nine weeks ago; is suckling. Complains of asthenopia when reading or sewing, since confinement. V each eye $\frac{6}{9}$; no hypermetropia; requires + 2 D to see Jaeger 1 at a convenient distance.

CASE 5.—Miss W——, aged forty, governess, single. Had "gastric fever" in May this year; laid up several weeks. Catamenia irregular; occasionally misses a period. Complains of recently acquired asthenopia, especially of the left eye, when reading. V right eye = $\frac{6}{9}$; left eye = $\frac{6}{12}$; not so good with + 1 D. With right eye reads Jaeger 1 at 22 cm.; with left can only read Jaeger 6, but with + 2 D reads Jaeger 1, and ten minutes after the instillation of eserine she can do the same without assistance.

The following case was presumably referable to antecedent small-pox.

CASE 6.—Sarah C——, aged twenty-nine; married; four children, last eight months ago. Sixth months ago contracted small-pox severely; vaccinated (three marks). A fortnight after recovery she noticed she could neither sew nor read, and this condition has continued up to the present time. V with each eye = $\frac{6}{9}$ c + 2 D = $\frac{6}{9}$; but with this hypermetropia corrected she can only read Jaeger 16; with + 6 D reads Jaeger 1, and twenty minutes after the instillation of eserine she could do the same without assistance. Pupils rather dilated, but acted to light. She also complained of dysphagia, and on drinking a glass of water much of it returned through her nose; so that the soft palate was also paralysed, as indeed could be seen on inspection. Under tonic treatment and weak eserine drops she completely recovered.

The cycloplegia of lactation is most common in young multiparæ, in hypermetropes, and in those naturally delicate or otherwise debilitated; it is seldom complete, the iris is rarely affected, and their visual acuity is usually less than normal. This latter fact is probably to be accounted for by the presence of some retinal asthenopia or anæmia; Mr. Hutchinson,[10] in recording a case of loss of accommodation from nervous shock, insists on the "important distinction to be drawn between a sudden failure of sight from this cause and from epilepsy of the retina." The condition of the retina in epilepsy we know to be that of extreme ischæmia; and it is common to see an unusually grey or anæmic fundus in the puerperal state, and occasionally this may culminate in epileptic amaurosis. I was asked some two years ago by Dr. Godson[11] to examine the eyes of a woman on whom he had three days previously successfully performed Porro's operation, and who had become suddenly blind. The question of embolism had been raised. The symmetry of the lesion rendered such cause improbable, and on ophthalmoscopic examination I saw the most anæmic fundus I have ever observed. I gave a favourable prognosis, which was justified by the sequel.

The treatment of these cases of enfeebled accommodation

is good diet and some preparation of iron—the ammoniocitrate appears to be the most efficacious. In cases due to lactation it is desirable to suggest an early weaning of the child. The prognosis is extremely favourable. As regards causation, this appears to be in no respect different from that of the cyclopiegia of diphtheria and other debilitating diseases. The blood of the pregnant and puerperal woman "is deficient in albumen, and the amount of coloured globules is materially diminished."[12] It would appear that there is no specific cause at work, but that mere anæmia is sufficient to occasion either accommodative asthenopia, which may amount to complete cycloplegia, or retinal asthenopia, which may culminate in epileptic amaurosis.

Albert-terrace, N.W.

COMPLETE AMPUTATION OF MALE GENITALS FOR RECURRENT EPITHELIOMA.

By ROBERT JONES, L.R.C.P. ED., M.R.C.S.
HONORARY ASSISTANT-SURGEON, STANLEY HOSPITAL, LIVERPOOL.

S. K——,[1] of good family history, aged twenty-nine years, came to me in April, 1885, suffering from a hardened condition of the end of his penis. There was a small superficial ulcer, which gave rise to very little pain and discharged a small quantity of thin pus. He denied emphatically ever having placed himself in the way of syphilis, and stated that the hardness of the penis had more or less obtained for three months, the ulcer for a fortnight or three weeks. The glands of the groin were enlarged and hardened, and erections of the penis, which were very frequent, were also very painful. Being in some doubt in regard to malignancy, I placed the patient under a mercurial course, and watched the progress of the ulcer. For upwards of three weeks it underwent no perceptible change; its edges were not ragged; there was but little pain; no tendency to bleed or excavate. The edges were barely raised above the surface, the base even, and no eversion of the borders. In fact, it presented no marked features of epithelioma. The induration, however, rapidly increased, until half the penis was of a characteristic leaden consistence. The diagnosis, which was no longer doubtful, was shared by Mr. Rushton Parker and Mr. O. Thomas, and the penis amputated early in May, just in front of the pubes. The patient was at his work in a fortnight, the enlarged inguinal glands having meanwhile subsided. For over seven months the patient was completely rid of the disease, but at the end of the year he complained of soreness at the end of the stump. He came to me in January, when I found the disease had returned at the site of amputation, which was occupied by a tumour, painful on pressure, and freely discharging pus through the urethra. The inguinal glands had again become enlarged, and difficulty was experienced in micturition. The scrotum in the neighbourhood of the urethra had become ulcerated, and the left spermatic cord was much enlarged and indurated about an inch from the inguinal canal. An operation being imperative, the patient was admitted into the Stanley Hospital towards the end of January, where, owing to the kindness of my colleague Mr. Sheldon, I was enabled to treat the patient.

On Feb. 4th, having made an incision through the length of the raphé of the scrotum, I came down upon the corpus spongiosum, and slowly dissected it from the adherent corpora cavernosa. The cavernous bodies were next followed to their origin, and with a blunt scalpel the crura were separated from the pubic arch. The corpus spongiosum was then divided, the posterior part being left of sufficient length to easily reach the perineal skin wound, the anterior part being included with the cancerous mass.[2] The left testicle was now removed, the involved cord being dissected high up and secured in the inguinal canal. The right testicle was next excised, together with most part of the scrotum, excepting a flap, into which I made a slit for the reception of the urethra and brought down like an apron over the perineum. The edges of this flap were stitched to surrounding structures, and the urethra made secure to the central opening. The wound was kept as fresh as possible, the patient placed upon light dietary, and an indiarubber catheter maintained in position. The temperature rose to 102° upon the second day, but was reduced, and he recovered, without any symptom of interest, in three weeks. In seven weeks he was able to work.

Several cases have been lately reported where the crura have been dissected from the rami after the manner first described by Mr. Pearce Gould. But I have only met with the reports of two cases where the dissection was as complete as that which I now report. One was a case described by Professor Annandale some years ago, where, if my memory does not fail me, he removed the penis and testes, but did not clear the pubic arch. The other is reported by Mr. Wheelhouse of Leeds, where, if I understand his description, the organ was severed anteriorly to a ligature or switch placed around it in front of the triangular ligament, and he further advised that, should any of the remaining portion of the crura look suspicious, it had better be clipped away. In any case I think it would be well to remove the whole of the crura at once, on the same principle that it is wise to remove the whole and not merely a section of the breast for scirrhus; it adds but little to the complexity or danger of the operation, and may be the means of preventing a recurrence. The case I have reported is also interesting inasmuch as the patient was only twenty-nine years old, and had never been the subject of phimosis. His inguinal glands at the time of operation were extremely hard, and I was sorely tempted to remove them. Indeed, in a few days after operation they felt so thoroughly malignant that I appointed a day for their excision. In a few days, however, the hardening quite disappeared. This accords with the observation of other surgeons. In my own practice I have had to deal with only four cases of epithelioma of the penis, in three of which I performed the ordinary flap amputation. In one case a recurrence occurred in the glands twelve months after operation. In the remaining three cases the stump was the seat of attack. In that where the glands became affected they were normal in every way at the time of the amputation, whereas in the other three instances they were enlarged at the time of the operation, but subsequently became healthy. Six months have now elapsed since the operation, and there is no sign of return. The patient is at work; has, of course, full bladder control, and suffers no manner of inconvenience except from a superabundance of skin, which is apt to become damp and irritable, but only to a very slight extent. The general conclusions I have arrived at with regard to future cases are: (*a*) when the diagnosis of epithelioma is beyond question, and the patient of a suitable age, the amputation should include the crura; (*b*) that the testes should, in the majority of cases, be removed; (*c*) that a scrotal flap should be saved as a covering for the perineum; (*d*) that there should be no hurry about excising enlarged inguinal glands; (*e*) the higher up the artificial penis can be brought, the more convenient to the patient, and the sooner it will unite to the surrounding tissues, as the discharges gravitate to the most dependent parts.

Liverpool.

[1] Shewn at the Liverpool Medical Institute.

[2] In dissecting I made a small puncture in the tense corpus spongiosum, and experienced great difficulty in controlling the hæmorrhage, which only ceased by leaving a Spencer Wells forceps upon the gap for about twenty-four hours.

TWO CASES OF HYPERPYREXIA OCCURRING IN THE COURSE OF ENTERIC FEVER.

By GRENVILLE E. MOFFET, M.B.,
SURGEON, ARMY MEDICAL STAFF.

HYPERPYREXIA occurring in the course of enteric fever is, I think, of sufficient importance to justify the publication of the following two cases:

CASE 1.—M. W——, aged twenty, was admitted into hospital on Aug. 2nd, 1885. He had been feeling unwell for about ten days before admission, the chief symptoms then being slight chills towards evening, headache, restlessness at night, nausea, and frequent epistaxis, with slight diarrhœa—three or four stools daily. On admission, he complained of headache (frontal), rachalgia, and general weakness. Face flushed; eyes suffused; skin hot and dry. Temperature in axilla at 10 A.M., 102·8°; tongue dry, red at tip and edges; pain on pressure and gurgling in iliac fossæ; a few rose-coloured spots over abdomen, which was slightly

tympanitic; spleen distinctly felt under margin of ribs; heart sounds normal, but weak; pulse 120, weak and compressible; dulness over bases of both lungs; firm crepitation over right base and large subcrepitant râles over left; respiration 24 per minute. He was ordered poultices to the back of the chest, and an enema of starch and laudanum to control the diarrhœa; milk and lime-water (equal parts), and beef-tea thickened with arrowroot, to be taken in small quantity every hour. At 7 P.M. the patient was not any better. Temperature 104°; pulse 130, very weak and compressible; delirium, with subsultus tendinum and muscular tremors; two loose stools since morning; slight epistaxis. To have half an ounce of brandy every second hour during the night. At 10 P.M. there was considerable epistaxis, which was controlled by a hypodermic injection of ergotin. For the next six days there was no amendment in the patient's condition. The adynamia became more pronounced; he lay on his back low down in the bed; his gaze was fixed and stupid; the pulse was small and very compressible, ranging from 120 in the morning to 140 in the evening; there were fibrillary muscular tremors, subsultus tendinum, and sordes on the teeth and on the tongue, which was hard, dry, and brown; the respiration was laboured and hurried; the temperature ranged from 102·6° to 103·2° in the morning, and from 103° to 105·2° in the evening, till on the evening of August 9th it reached 107·2°. At this time the patient was in a state of high delirium, the radial pulse was hardly perceptible, respiration 66 per minute, and there was great restlessness and floccitation. It was resolved, under the circumstances, to try the effect of the wet pack, as the patient seemed dying, and that rapidly, from an overheated condition of the blood. An enema of two ounces of iced brandy having been administered, the patient was enveloped in sheets wrung out of water at a temperature of 80° F., the water being gradually cooled down to 50°. The effect of the wet pack is seen in the following table:—

Time P.M.	Temp. of bath.	Temp. of patient in axilla.	Remarks.
8·30	80°	107·2°	Condition of patient as described above. Enema of 2 ounces of iced brandy.
8·45	80°	107·4°	—
9·0	60°	108·0°	Respiration 68; restless.
9·15	60°	106·0°	—
9·30	60°	105·2°	Pulse 140; respiration 68. Enema repeated.
9·50	50°	103·8°	Pulse 120, stronger; respiration 60.
10·5	50°	101·6°	Tongue moist; delirium less; pulse 120. Wet pack stopped.

On stopping the wet pack the patient was removed to another bed, dried, and covered with a single blanket, two ounces of warm beef-tea being given at the same time. The tongue was moist, skin soft, no floccitation, and the pulse full and much stronger. At 11.30 the temperature was 101°, but by 12 midnight had again risen to 105°, when the wet-pack was again employed, with the effect of reducing the temperature at 2.30 A.M. to 102·2°; the pulse, however, was very quick and small (over 140), respiration 64 and laboured, lips livid, and face cyanosed. By 3 A.M. the temperature had risen to 105·8°, and at 3.15 the patient died.

Necropsy, nine hours after death.—Body emaciated. Cranial cavity: Membranes congested; sinuses engorged; ventricles contained a small quantity of serous fluid; brain substance congested; weight, 86 oz. Thorax: The lungs did not collapse on opening the thorax. Weight of right lung, 26½ oz.; lower two-thirds consolidated (red hepatisation). Left lung œdematous at base; exudation of frothy fluid on section; weight, 17½ oz. Heart: Weight, 17¾ oz.; contracted; veins engorged; valves healthy; pericardium empty. Abdomen: Peritoneum slightly thickened; mesenteric glands much enlarged, size of small almonds, softened, and of a deep plum colour. Liver: Weight, 77 oz.; hyperæmic. Spleen: Weight, 31 oz.; greatly enlarged, congested, and softened. Kidneys: Weight, 7 oz each; capsule adherent; medulla slightly injected. Intestines: Mucous membrane congested, the lower third being of a slate-grey colour; softened at parts, and more deeply congested in lower half of jejunum and ileum, Peyer's patches being also prominent and congested in these parts; ulceration very slight, being limited to three small ulcers about the size of threepenny pieces in the ileum, near the ileo-cæcal valve. The solitary glands of the ascending colon were prominent and congested, but there was no ulceration. The mucous membrane was slightly injected.

CASE 2.—G. T——, aged twenty-three, was admitted into hospital on Aug. 6th, 1885, with symptoms precisely similar to those of M. W——, but there was no epistaxis; the diarrhœa was greater, there being ten or twelve stools in the twenty-four hours; the tongue was dry and brown, with sordes on the teeth. The temperature at 10 A.M. was 103°, pulse 130, and respiration 48 per minute. Patient had been feeling ill for a fortnight before admission; he was therefore in a more advanced stage of the disease than the last patient. He was ordered ten grains of aromatic powder of chalk and opium, after each loose stool, to check diarrhœa; also to be given half an ounce of brandy every hour in milk; in other respects the treatment was similar to that adopted in the last case. At 7 P.M. the patient was very delirious; temperature 105°; pulse 148. The bowels had not been opened since 2 P.M. A draught of chloral hydrate (25 grs.) was prescribed, and an ice-bag was applied to the head. On the 9th he was somewhat better. Temperature at 9 A.M. 103°; tongue moist. Slept fairly well previous night; pulse 126, stronger; two loose stools since 6 A.M. On the 10th there was a decided change for the worse; delirium had supervened, and the patient was wild and noisy, having to be held down in bed; marked tympanites. He was ordered turpentine stupes to the abdomen, an enema of two drachms of tincture of assafœtida to a pint of tepid water, and small pieces of ice to suck; three leeches were also applied behind each ear. At 8 P.M. the delirium was less and the tympanites somewhat relieved, but otherwise there seemed no improvement. The temperature had risen to 108° (rectum); pulse 148, small and compressible; breathing shallow and laboured, 62 per minute. It was resolved, after consultation, to try the wet pack also in this case, the details being carried out in precisely the same manner as in the last case, and with the following result:—

Time P.M.	Temp. of bath.	Temp. of patient in rectum.	Remarks.
8·40	80°	103·0°	Pulse hardly perceptible at wrist; heart sounds feeble. Enema of 2 ounces of iced brandy.
9·0	60°	103·6°	—
9·20	60°	107·2°	Pulse 132, more volume; respiration 44.
9·40	50°	106·4°	Enema repeated.
10·0	50°	103·8°	Pulse 136; respiration 40; tongue more moist; involuntary evacuation of bowels. Wet pack stopped.

At 11 P.M. the temperature had risen again to 106°; pulse 130, feeble and fluttering; respiration short and hurried, 44 per minute. An iced enema of an ounce of brandy with an ounce of milk was administered, but was not retained. It was not considered advisable to try the wet pack again, as the man seemed rapidly sinking. At 12.10 A.M. the temperature had reached 109°, and remained at that height till 1 A.M., when death took place.

Necropsy, eleven hours after death.—Body emaciated. The cranial cavity presented the same appearances as in Case 1. Weight of brain, 63½ oz. Thorax: The lungs did not collapse on opening the thorax. The right lung weighed 22 oz. and the left 20½ oz.; both œdematous at base. On section a large quantity of frothy fluid exuded from the bronchi; retro-bronchial glands greatly enlarged, and of a dark bluish-grey colour. Heart: Weight 11 oz.; healthy; no fluid in pericardium. Abdomen: Peritoneum firmly adherent to the intestines, especially to the jejunum and ileum; mesenteric glands very much enlarged, softened, and of a dark slate colour. Liver: Weight 62 oz.; slightly hyperæmic. Spleen: Weight 13½ oz.; softened and friable. Kidneys: The right kidney weighed 6 oz. and the left 8 oz.; cortex pale; medulla greatly injected in both. Intestines: The mucous membrane of the small intestine was of a dirty brickdust colour, and softened. Twelve or fourteen ulcers corresponding to the patches of Peyer, and [illegible] in size from half an inch to

two inches in diameter, were seen extending from the ileo-cæcal valve to the lower part of the jejunum, those at the lower end of the ileum having a gangrenous appearance. The patches of Peyer in the upper half of the jejunum were prominent, congested, and surrounded with vascular rings, the mucous membrane over them being softened. The mucous membrane of the cæcum and ascending colon was deeply injected throughout, and presented several small ulcers (corresponding to the solitary glands), many of which had coalesced to form larger ones.

Remarks.—Both the above patients were soldiers, about the same age, living under the same conditions as regards food, surroundings, &c., and both came from the same barrack-room. It is interesting, therefore, to note (1) the marked similarity of the symptoms and the nearly identical course of the temperature; (2) the marked difference in degree of the intestinal lesions; and (3) the great disproportion between the temperatures and the intestinal lesions in the two cases. This last point bears out what Wunderlich says regarding the course of temperature in disease. "Even when the *course* of the temperature," he says, "is identical in two cases of fever, it by no means follows that both originate in the same way. It is, on the contrary, highly probable that the opposing circumstances of production and loss of heat in different cases, and even with an identical height of temperature, may vary very greatly."

Gibraltar.

ON A CASE OF SUPPURATION OF THE MASTOID CELLS SIMULATING INTRA-CRANIAL ABSCESS.

By EDWARD COTTERELL, M.R.C.S., L.R.C.P. LOND.

IN the following case it will be seen that the history and symptoms pointed apparently to an intra-cranial abscess, so much so that the question of trephining, with a view to evacuating the confined matter, was discussed; but before proceeding to this somewhat hazardous operation, a free opening was made into the cells of the mastoid process, with the result of completely relieving the urgent symptoms and ultimately curing the middle ear disease. In using the words "hazardous operation," I do not mean to imply that the operation of trephining is *per se* hazardous, because, with all the resources of antiseptic surgery at our command, it is difficult to believe that there is any risk in the operation when carefully performed, but the hazardous nature of the proceeding in an intra-cranial abscess consists in hitting off the exact spot to trephine in order to evacuate the matter. The difficulty in diagnosing the exact locality of the abscess is admittedly very great, as the symptoms are in most cases vague and unreliable, whilst the differential diagnosis between a limited collection of pus in the cerebrum or cerebellum, and between a limited or diffuse meningitis, is beset with difficulties which in the present state of our knowledge it is impossible to overcome; but I think that most surgeons will be inclined to agree with the following statement made by Mr. Hulke in reference to these cases. He says:[1] "However, the fact that the clinicist is not yet in the position to form a certain judgment concerning the precise nature of the local disorder does not, in the presence of the almost certainly fatal termination of the otitic intra-cranial abscess when left to take its natural course, exonerate him from further efforts; when his judgment attains a high degree of probability, the propriety of a surgical operation for the evacuation of the abscess should be faced."

H. F——, a young lady aged fifteen, has the following history. Nine years ago, whilst playing one evening, she introduced a bead into her left external auditory meatus, and in trying to extract it only pushed it further in. The next morning she was taken to see a medical man, who made fruitless efforts to extract it. Two days after this she was taken to another surgeon, who endeavoured, whilst the child was under the influence of chloroform, to get the bead out; but he also failed. Nothing further appears to have been done, and chronic suppuration of the middle ear was naturally set up. Six months after its introduction the bead dropped out whilst she was having her ear syringed. But the expulsion of the foreign body did not cure the middle ear disease, and since that time she has suffered from chronic otitis media purulenta, the discharge being most offensive, and often making her sick by trickling down the pharynx. In February, 1885, she began to complain of intense headache, accompanied with vertigo. Gradually she became very strange in her manner, getting very excited at times, screaming at the top of her voice, and biting her fingers, bedclothes, or anything that came in her way. These symptoms became intensified at night, and her screams, or rather yells, quite disturbed the neighbours. Her head was shaved and ice applied to it. Large doses of bromide of potassium were administered in the day with chloral at night, but the symptoms rapidly became more severe and intensified; as photophobia came on the headache became very much worse, and about this time tenderness was noted over the mastoid process of the left side. The screaming fits now became much more severe and prolonged, and during her paroxysms she would jump up and throw herself about the bed, becoming very violent and attempting to bite anyone who touched her. The optic discs were normal.

At this stage I came to the conclusion that the case was either one of meningitis or of abscess within the cranium, as the symptoms seemed too severe for pus pent up in the mastoid cells. Having obtained permission of her friends to operate, I determined first of all to trephine the mastoid cells, and see if that would do any good, though I confess I had no faith that it would; and should no pent-up pus be found there, I was prepared to trephine over the temporo-sphenoidal lobe and explore that region for an abscess, or, if a limited meningitis were found, to wash out and drain—treating it, in fact, as an ordinary abscess. Accordingly, on March 9th, the patient being under the influence of chloroform, an incision was made over the left mastoid process, and the cells thoroughly opened up with a gouge. About a drachm of fetid pus was evacuated, and then a free communication was established between the external wound and the tympanum with a tooth elevator. A small drainage-tube having been inserted, iodoform powder was blown in and the wound dressed with iodoform wool. On recovering from the anæsthetic her headache was better and she had no more delirium or screaming fits. The wound healed by granulation, small scales of dead bone occasionally coming away. It is now over eighteen months since the external wound closed, and since then she has been completely free from all discharge and from pain in her ear and head, so that I think she may be looked upon as cured.

Ilkeston.

[1] THE LA[illegible]

A CASE OF DIPHTHERIA OF THE VAGINA WITHOUT THE THROAT BEING AFFECTED.

By SURGEON JAS. B. CLIBBORN, R.N.

(*Communicated by the* DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.)

MRS. T——, the wife of a private in the Royal Marine Light Infantry, when attending her child, who was suffering from diphtheria, was scratched by him on her right wrist. Some days after (time uncertain) a few isolated, inflamed, vesicles that were very painful appeared on the wrist, which implicated the glands at the bend of the elbow and axilla. There was no pyrexia, and the throat was not affected. The wrist soon healed under treatment, and the inflammation in the glands subsided, when a fresh crop of vesicles appeared around the nipples of both breasts; there was still no rise in temperature, and the patient complained of little inconvenience beyond weakness and general malaise. The latter crop of vesicles went away as rapidly as those on the wrist, but the patient complained of weakness, daily increasing, accompanied by anorexia, with insomnia; she also stated that there was a fetid discharge from the vagina. On making a vaginal examination the mucous membrane was found to be greatly inflamed, discharging pus and covered in parts with well-developed shreds of false membrane. The constitutional symptoms now rapidly developed, asthenia increased, and the patient suffered at times from delirium and delusions, and had one well-marked epileptiform convulsion. The urine contained a small quantity of albumen. The highest temperature taken only

indicated 99·4°; the throat at no time presenting an inflamed appearance. The inflammation in the vagina daily increased, large shreds of false membrane, almost forming complete casts of the vagina, were discharged; asthenia was great; the pulse small and compressible; the pupils were frequently irregular, and responded feebly to light. About this period of the disease the patient (who was five months pregnant) was attacked with well-marked labour pains, occurring at regular intervals. As it was considered that, should a miscarriage take place, the disease would extend to the uterus, with a probably fatal issue, very large doses of opium were given with a view of stopping the uterine contractions, which had the desired result after the patient had taken about five grains of this drug. Under treatment the discharge from the vagina became less, and the development of false membrane decreased till about ten days after its first appearance, when it had entirely disappeared. Convalescence rapidly took place, and the patient, who was removed to the country, was subsequently delivered of a living child, with no bad results.

Treatment.—Carbolic acid combined with quinine was given internally every three hours (each dose containing one minim of carbolic acid, ten minims of glycerine, and one drachm of tincture of quinine, in an ounce of water), the urine being carefully watched during its administration. Iodoform was applied locally with vaseline (a drachm to the ounce). When the vagina became affected, it was frequently washed out with a solution of permanganate of potash. Strips of lint soaked in iodoform and vaseline were introduced into the vagina and changed every few hours. Stimulants and strong liquid food were given in large quantities when the asthenia was great.

Remarks. This is one of several cases I have treated with carbolic acid and quinine given internally in this disease; the results so far have been more satisfactory than any other treatment I have seen tried. The cases in which it has been adopted have, however, been too few as yet to merit more than a suggestion that it is worthy of a more extended trial.

POISONING BY BENZOLINE VAPOUR.

By A. G. R. FOULERTON, M.R.C.S., L.R.C.P.,
RESIDENT MEDICAL OFFICER, ROYAL ISLE OF WIGHT INFIRMARY.

POISONING by benzoline is of sufficiently rare occurrence to warrant the recording of the following case, in which, however, as will be seen, the effects of the poison may have been complicated to some extent by the high temperature in which the patient was at the same time placed.

W. S——, aged twenty-five, a well-made and healthy-looking German, entered a zinc tank used for the storage of benzoline, and then all but empty, at 9 A.M., and at 11 A.M. was found lying insensible at the bottom of it. The tank was some 5 ft. 6 in. high, with a small man-hole at the top, and exposed to the direct heat of a powerful sun, a thermometer inside registering 105° F. Shortly afterwards, when the man was brought to the infirmary, I found him in the following condition: Smelling strongly of benzoline; unable to stand, but capable of answering simple questions in an indistinct sort of way; moaning occasionally, and from time to time bursting into a hysterical laugh; face flushed; surface of body and limbs cold and clammy; muscular tremors and twitchings in the legs and arms; pupils widely dilated, reacting to a strong light stimulus; pulse 88, full and soft; respiration from 8 to 9 in the minute, deep and stertorous, irregular in rhythm, as much as fifteen seconds intervening between the separate inspirations; heart's action feeble; temperature in axilla 98·8°. Shortly after admission he vomited freely, the ejected matters being bile-coloured and smelling of benzoline.

The man was given at once twenty-five minims of solution of ammonia with half a drachm of ether and put to bed, wrapped up in blankets, and hot-water bottles used. He then had half a drachm more of ether with some brandy, and was given frequent half-drachm doses of aromatic spirit of ammonia. For about two hours the patient remained in much the same condition, becoming at times absolutely unconscious, his breathing also getting worse at intervals. At the end of that time he began to improve rapidly, and was soon afterwards able to give a rational account of himself, but could not say how long he had been in the tank before he lost consciousness. His pupils were still dilated, and he complained of bad headache. He then had an attack of profuse sweating, and by the evening had completely recovered, no trace of his misadventure remaining beyond some slight headache. The temperature and respiration were normal, and the pulse 76. The urine passed presented nothing extraordinary, and a motion following the administration of half an ounce of castor oil was of a dark-green colour.

From these symptoms it will be seen that benzoline is a well-marked example of an inebriant poison. It was not thought necessary to give an emetic, as the man had merely been exposed to the vapour and had not swallowed any liquid benzoline; he settled the matter, however, by vomiting spontaneously. Theoretically, brandy and ether (being themselves inebriants) would seem to be contra-indicated, but the result was sufficiently satisfactory to justify their use. Looking back on the case, I cannot help thinking that the man might have been further benefited by a little blood-letting, for I regard the main symptoms as pointing to failure of the heart's action, diminished capillary tension, and consequent stagnation in the venous system, with over-distension of the right side of the heart. Were a similar case to occur to me again, I should be content, I think, with the application of external warmth and moderate bleeding and the free use of ammonia.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

UNIVERSITY COLLEGE HOSPITAL.

SARCOMA OF THE RECTUM; LITTRÉ'S COLOTOMY; RELIEF; REMARKS.

(Under the care of Mr. ARTHUR E. BARKER.)

THE malignant growth met with in the rectum is almost always the adenoid or cylindrical epithelioma, sometimes undergoing colloid degeneration. Scirrhus and encephaloid are very rare, and it is probable that recorded cases of the latter will become fewer as the microscopical examination of these growths is more regularly conducted, many cases which would otherwise have been classed as encephaloid proving to be of sarcomatous nature when thus examined. The reasons which induced the operator to prefer Littré's operation to that of left lumbar colotomy, which is usually practised when local removal of the growth is impossible, will be found in the remarks appended to the case.

H. A——, aged thirty-eight, a labourer, was admitted into University College Hospital on July 29th, 1886, on account of diarrhœa alternating with obstruction of the rectum, and severe pain, the result of growth in the bowel. His sufferings began with violent diarrhœa in the previous March, which lasted about two months, and was followed in June by constipation. On straining blood was passed, but pain was not complained of until the end of June. It was then a well-marked symptom, especially at night and during efforts at defecation, which were usually fruitless.

On admission a large mass of growth could be felt in the rectum, almost completely surrounding the bowel. It was soft and lobulated, and completely blocked the passage. A portion of it, as large as a hen's egg, was broken off with the finger by Mr. Heath on July 30th, and was found on microscopical examination to consist of fibro-sarcoma. Profuse bleeding followed, but was checked by plugging of the rectum. As there seemed no prospect of benefit from any local operation and the patient's sufferings were severe, it was determined to open the colon and establish an artificial anus. This was done by Mr. Barker on Aug. 18th by Littré's method. All antiseptic precautions having been observed, an incision was made from a point just internal to the anterior superior spinous process of the ilium, downwards and inwards for about three inches [illegible] about an inch above Poupart's

ligament. The several layers of muscle were divided on a director until the subperitoneal tissue was reached. Only three small vessels required attention and were closed by forcipressure. When all oozing had been arrested and the wound had been thoroughly dried, the carbolic spray was turned on and the peritoneum was opened in the direction of the skin wound for about an inch and a half. The parietal peritoneum was then stitched over the cut muscles to the skin by four fine silk stitches on each side. Into the now funnel-shaped opening a portion of the sigmoid flexure of the colon was drawn and secured. It had not at once presented in the wound, but was easily found on pushing aside the coils of small intestine which at first appeared. There was not the slightest difficulty in drawing it into the desired position or fixing it. This was done by means of eight fine silk sutures on either side and one extra one at the angle where it seemed to be needed. These sutures only passed through the serous and muscular coats of the bowel and then through the parietal peritoneum and skin. Special care was observed to obtain firm contact of the two serous surfaces at each angle of the wound. The surface of the gut included by the oval of stitches measured about an inch long and half an inch broad. The operation was completed by closing the angles of the skin wound by silk sutures, but the bowel was not yet opened. The area of operation was then dusted with iodoform and dressed with strips of salicylic wool; over these a thick pad of ordinary wool was secured by a spica bandage.

After the operation the patient was very comfortable, sleeping and taking food well. The rectum continued for the first few days to discharge thin sanious mucus from the growth, but little or no fæces. There was no pain either in the rectum or the wound, and his general condition was excellent. The first dressings were not disturbed until the fourth day, when the wound was found in a most satisfactory condition. The surface of the bowel bulged forwards into the opening, and was covered with almost dry plastic lymph, which united it also to the parietal peritoneum. There was no irritation about the stitches. The same dressing was applied as before. The wound was again uncovered on the sixth day, and was observed to be healing perfectly. The patient's state was so satisfactory that the bowel was not opened till the eighth day. The prominent area of the bowel was then simply notched with scissors, and an opening an inch long made through all its coats. These were now everted and secured with four silk stitches. Hard scybala were seen in the opening, but were not disturbed. Iodo-vaseline was now smeared round the edges of the wound and skin, and a pad of oakum was laid over all. No anæsthetic was used for this opening of the bowel, and so perfectly well did the patient feel that he asked "was he not to get off the operation-table and walk into the ward." After this convalescence was uninterrupted. There was no trouble with the wound, the angles of which healed partly by granulation. On the tenth day a hard motion was passed by the new anus, which continued henceforth to act regularly, nothing but bloody slime passing by the rectum. In order to check this latter discharge if possible, the rectum was washed out both per anum and by the new opening with water, and later with a decoction of hæmatoxylin. Iodoform bougies were also introduced, but the running from the surface of the growth continued. Beyond this the patient's general condition was as good as could be. The bowels acted regularly, sometimes aided by aperients; the new opening working admirably; no fæces passed by the rectum. The patient was able to attend to his bowels himself, and to cleanse the parts after each motion thoroughly. He remained in hospital (up each day) until Oct. 8th, and then left for Highgate Infirmary. It was plain, however, that the cachexia was increasing before he left.

Remarks.—After alluding to the comparative rarity of sarcoma of the rectum, of which this was a typical example, Mr. Barker said that he was led to adopt Littré's method of opening the colon—i.e., in the groin—from the following considerations:—In the first place the seat and amount of the obstruction was well known, and also the extent of the growth. There was consequently every prospect of finding the sigmoid flexure quite healthy so far above the latter. The opening in the groin is easier to get at during a motion, and easier to cleanse afterwards, than one in the loin. Although the peritoneal cavity is opened in Littré's operation, the use of antiseptics reduces the consequent risk almost to vanishing-point; moreover, the difficulty of avoiding injury to the [illegible] Amussat's method is considerable, and the membrane is often wounded. The operation in the groin is, on the whole, easier in cases in which there is not extreme distension of the colon. In such cases, where immediate relief of the obstruction is demanded, the operation in the loin is probably the safest, and perhaps the easiest. But where the obstructive symptoms are not very severe, and the bowel can be left unopened for a day or two, Mr. Barker would prefer Littré's operation, as giving more comfort to the patient, the opening being more under his control than if in the loin.

TOTTENHAM HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF SKULL; TREPHINING; RECOVERY.

(Under the care of Dr. E. HOOPER MAY.)

WALTER B——, aged seven years, was admitted on April 15th, 1886. He was throwing stones at a cart-horse which was loose on the marshes, when it turned suddenly and kicked him on the forehead. He was found to be suffering from a compound depressed fracture of the frontal bone. The wound was to the right side of the middle line, and extended out and down immediately above the supra-orbital ridge for a distance of two inches. The two tables of the skull were seen to be driven in beyond the level of the inner table of the surrounding bone. The hæmorrhage from the wound was considerable; there was no escape of brain substance, but serum was discharged as well as blood from the wound. He vomited frequently, the vomit consisting of his recently partaken dinner. No squint, no paralysis, and no pain. He appeared to be drowsy, at times lapsing into stupor, which lasted about a minute and a half, the face becoming blanched; on return of consciousness he cried to be taken home, and resented any examination of the wound. Pulse 72.

Chloroform being administered, the wound was enlarged and a disc of bone raised from that surrounding the outer edge of the depressed portion. A small trephine was employed, and by means of necrosis forceps three-fourths of the outer part of the depressed fragment was removed with some difficulty owing to the firm impaction. The remainder of the depressed bone was raised to the level of the surrounding bone and a large separated piece of the inner table removed. The sharp corners of the perforation in the skull were snipped off with bone forceps. The dura mater was found to have a small perforation at the lower part of the wound. The edges of the wound were united by sutures of carbolised silk, a rubber drainage-tube inserted, and a dressing of dry perchloride gauze and salicylic wool applied, with a gauze bandage stitched over to form a cup. The pulse, which had during the operation gone down to 60, now rose to 72. He was sick several times after the chloroform, and once vomited dark blood. The diet ordered was milk and beef-tea, and a powder of three grains of calomel was prescribed at bedtime. A subcutaneous injection of morphia was administered during the night because of restlessness. It produced sleep, although disturbed at times by sudden cries.

April 17th.—The bowels had not acted since admission; restless. Calomel powder repeated. Feels hungry; crying out for solid food. Wound dressed; tube removed; only small quantity of sanious discharge. Perchloride of mercury lotion (1 in 1000) used to irrigate wound.

18th.—Calomel had acted; appetite somewhat impaired. The wound was not dressed again until the 24th, when the sutures were removed. The edges had united except where the tube had been.

May 17th.—Temperature 100° F., with an evening one of 99°, apparently due to a slight catarrh. It had never risen above normal previously, and in a few days subsided to its former condition.

28th.—He was discharged with wound firmly healed. The scar was in the form of two sides of a triangle, the apex pointing down, each side enclosing the angle measuring an inch and a half. The perforation in the bone was felt to be uniform, and measured an inch and a quarter by half an inch. So that as the bone removed measured two inches by one, there had evidently been considerable formation of new bone. Pulsation of the brain was felt through the perforation in the skull. The intellectual faculties were extremely active, his aptitude for mental arithmetic being exceptional.

ST. GEORGE'S HOSPITAL FOR DISEASES OF THE SKIN, LIVERPOOL.

ULCERATING POST-NATAL NÆVUS.

(Under the care of Mr. RICHMOND LEIGH.)

A. G——, aged four weeks, when first seen, had a peculiar nævoid patch in the right temporo-malar region, about six inches in length by two and a half in width. There were similar smaller patches on the upper lip and ear, and others, very small, in the scalp. The various patches had each the exact appearance of a nævus, were slightly elevated above the surface of the skin, and varied in vividness of colour according to the state of the circulation, being brightest when the child was excited, especially when crying, and palest when it was sleeping. The main patch was slightly ulcerated in places. The first appearance of the disease was at the age of two weeks, and the growth had since then rapidly increased to the size mentioned. The child's general health was good; it was well-nourished, and had only its mother's milk. The disease improved slowly under treatment, disappearing in some parts while extending in others; but, on the whole, not much progress was effected. Ethylate of sodium was applied to a portion of the growth several times, but without good effect, the scab caused by it, on being shed, leaving an ulcerated surface. This ulcerative tendency prevented the use of strong remedies, and, in spite of treatment, proceeded, in the patch affecting the ear, almost to gangrene, eating through a portion of the lobe. No ethylate had been used to this part. Subacetate of lead and zinc ointments were used with some advantage, lessening the ulcerated surface, which was also effected by boracic cod-liver oil. Iodide of iron was given internally.

The parents leaving town, the child passed from under observation, the disease being still extensive, and having a malignant look in places. In spite of this, the child's health was better than it had been, the mother remarking that it was "getting fat." The case was under treatment for a little over four months, and when last seen the disease was rather less than at the beginning of treatment.

NEWCASTLE-ON-TYNE INFIRMARY.

SUBPERIOSTEAL SARCOMA OF TIBIA.

(Under the care of Mr. PAGE.)

WE are indebted for the notes of the following case to Mr. F. P. Maynard, M.B., house-surgeon.

R. H——, aged twenty-one, single, was admitted to Ravensworth ward on Sept. 9th, 1886, complaining of a swelling of the left calf. Had always enjoyed good health, and his family history was good. Six years ago he had his left ankle badly bruised by a horse. Last April he felt aching pain deep seated below the inner tuberosity of the left tibia, which was somewhat better at nights. A week later the knee became stiff and began to swell. The swelling, he says, was hard all over, well defined, immovable, not tender, the skin not being red, and it increased rapidly.

On admission he was found to be a tall man, weakly in appearance, and all organs healthy. The left leg lies on its outer side, semi-flexed; the thigh is atrophied. Situated on the inner surface of the upper third of the leg is a flattened oval swelling, commencing above at the line of the knee joint, and extending below to the upper portion of the middle third of the leg, being seven inches long, and reaching in front to the crest of the tibia; behind, it reaches beyond the middle line, filling the lower half of the popliteal space, measuring nine inches and a half in its broadest transverse diameter. Œdema extends about two inches beyond these easily defined borders all round. The tumour fluctuates all over, or, rather, is elastic; is deeply attached, but does not crackle anywhere. The skin over it is reddened, but not adherent, due to its having been blistered previously to admission. The leg and foot are much swollen from œdema. There is no fluid in the knee-joint, and neither swellings nor tender spots can be felt in the thigh or groin. An exploring needle drew off bloody fluid, containing large numbers of round, oval, and tailed white cells.

Mr. Page amputated through the middle of the thigh, using the continuous suture. On examination a tumour was found lying between the gastrocnemii and soleus, and spreading upwards till it was in contact with the margin of the semilunar cartilage of the knee-joint. It was yellow in colour, and lobulated on its surface; on section it presented a soft friable gelatinous substance, exuding an oily liquid on pressure, and containing numerous cysts, one as large as a hen's egg. At the upper portion it was developing into cartilage and calcifying. The tumour had not infiltrated the muscles, but had a thin but distinct capsule, which at its margins became continuous with the periosteum of the tibia. Where it was in contact with the bone—posterior and inner surfaces of upper end of tibia—there was no periosteum and no capsule, but the growth was invading the bone, making small excavations on its surface. Microscopic examination made by Dr. Limont showed the tumour to be a spindle-celled sarcoma developing into cartilage and calcifying in places.

This case differs from the majority of similar cases collected and described by Mr. Butlin in his work on Sarcoma and Carcinoma in three points only—viz., his cases generally affected older persons, showed a greater tendency to implicate the skin and fungate, grew more slowly, and were seldom of the spindle-celled variety; like his, the lymphatic glands were unaffected. The man is and will remain under observation.

GLASGOW EYE INFIRMARY.

TWO CASES OF CONICAL CORNEA; REMARKS.

(Under the care of Dr. J. CRAWFORD RENTON.)

CASE 1.—A. S——, aged twenty-two, was admitted on July 26th, 1885. Complains of dimness of vision in left eye, with which he can only distinguish light and shade. On examination, well-marked conical cornea is observed. Vision of right normal when aided by + 1·75 D cyl. placed horizontally.

July 27th.—Two drops of solution of cocaine (4 per cent.) were introduced into the left eye, the cornea being afterwards carefully bathed with antiseptic solution. When the cornea was non-sensitive, Bowman's medium-sized trephine was applied to the apex of the cone, and the layers of cornea carefully removed down to Descemet's membrane; through it the anterior chamber was punctured and the eye bandaged.

Aug. 15th.—Case has progressed favourably, and patient was dismissed, to return in two months.

Oct. 16th.—Readmitted. Iridectomy performed downwards and inwards.

Nov. 15th.—Sees No. 16, unaided by spectacles.

Feb. 20th, 1886.—Aided by + 3·50 D cyl. placed horizontally, he sees No. 6.

CASE 2.—H. C——, aged eighteen, was admitted on March 19th, 1886. Complains of dimness of vision in both eyes; sees No. 20 with right; counts fingers with difficulty with left. On examination well-marked conical cornea is noted in both eyes.

March 22nd.—The operation of trephining was performed, as above described, on the left eye.

29th.—The same operation performed on the right eye, the trephine not being carried so deeply as in the left.

April 19th.—Both eyes have progressed favourably, the left having a very dense cicatrix, the right much less so. An iridectomy was performed downwards and inwards in left eye.

May 7th.—Sees No. 6 with right eye and No. 14 with left.

July 14th.—Sees No. 4 with right eye and No. 8 with left; aided by – 3 D sph. the vision of left is raised to No. 4, so that the two eyes are equal for near objects. Distant vision is the same in both eyes.

Remarks.—The above cases illustrate well the value of Sir Wm. Bowman's admirable operation for conical cornea. The good result in the right eye of the second case, in which the trephine was not carried so deeply as usual, suggests the advisability of trying this in future cases. No proximate or remote cause could be discovered to account for the conical cornea. Both patients were healthy young lads who had not strained their eyes in any special manner; some congenital weakness must therefore be blamed for the defect until our knowledge is more perfect.

CENTRAL MEDICAL ASSEMBLY ROOMS FOR ST. PETERSBURG.—The Pirogoff Surgical Society of St. Petersburg is taking the lead in a movement for providing a central place of meeting for all the medical societies, where also accommodation will be [illegible] all their libraries.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Tuberculous Mass in Supra-renal.—Ascending Antero-lateral Tract.—Tumour of Palm of Hand.—Intra-bursal Fibroma. —Hyoidal Cysts.—Melanosis of Hard Palate.—Tumour of Palate.—Acute Necrosis of the Fourth Cervical Vertebra.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. Syer Bristowe, F.R.S., President, in the chair.

Dr. HARRINGTON SAINSBURY exhibited a specimen of Tuberculous Mass in the Supra-renal Body. The patient had a lumbar abscess, widespread tubercle, and lardaceous disease. The specimen contrasted with the change found in Addison's disease. Was the fibro-caseous change in the latter disease a primary or secondary one? Secondary affections were generally to be regarded as chance affections and subject to the laws of chance. If the bilateral supra-renal lesions of Addison's disease be tuberculose and secondary, there should, according to the law of chance, be a relatively large number of cases of unilateral secondary lesion like the specimen shown. Routine examinations of the adrenals was necessary to determine this. It was probable, however, that the lesion of Addison's disease was primary and to be regarded as a system disease.—Dr. KINGSTON FOWLER had seen cases of tuberculous masses in both supra-renal capsules associated with general tubercle. There was a difference in the appearances of these from those met with in Addison's disease.

Dr. COUPLAND exhibited a specimen of Tubercular Affection of both Supra-renal Capsules from a man aged forty-six, in whom there was also widespread disease of the urinary tracts. He was convinced of the tubercular nature of the adrenal change in Addison's disease. In four cases the bacillus had been found, and although Dr. Curnow and Dr. Maguire have not discovered the bacilli, still, as the latter remarked, they were not abundant in caseated areas. It was possible that the degree to which the change had advanced might explain the difference in the appearances of the capsules.—Dr. G. N. PITT said that in disease of the spine the supra-renal capsules were sometimes affected and probably secondary. In some cases of local sympathetic disease the skin was pigmented.—Dr. S. WILKS said that Addison's disease was evidently a primary disease; it was not tuberculous in the ordinary sense, but the outcome of a chronic inflammation like cirrhosis of the liver.—Mr. D'ARCY POWER had examined two cases of caseous disease of the adrenals associated with general tuberculosis and all the signs of Addison's disease.—Dr. HADDEN had shown a specimen in which no fibro-caseous change was present, but merely an interstitial fibroid change in a case of Addison's disease. In other cases both bodies were enormously enlarged; in some from tuberculous disease; in others from cancerous disease, but without the symptoms of Addison's disease. He thought a destructive change was a *sine quâ non* of Addison's disease.

Dr. SHERRINGTON gave an account of the Ascending Antero-lateral Tract of the Spinal Cord. He exhibited transverse sections of the spinal cord of the human fœtus of the seventh and eighth month. They had been stained with osmic acid &c., so that the developed tracts were black, and the other white matter with the grey matter were coloured pale yellow. Besides the pyramidal tracts, there were bands of undeveloped fibres in the periphery of the antero-lateral column, except where the direct cerebellar tracts were situate. The "ascending" tract begins at the front end of the anterior median fissure, and extends circumferentially back to the crossed pyramidal tract. This tract becomes fully developed late in fœtal life, and may be traced from the second sacral nerve upwards as far as the region of the antero-lateral nucleus. He wished to ascertain how far it corresponds to the ascending antero-lateral tract of Gowers and Hadden. There was another tract found degenerated in tabes dorsalis by Lissauer; it was wedge-shaped and situate near to the exit of the posterior roots; it extended throughout the cord, but not above the level of the decussation. In the dog there was no anatomical evidence of the ascending tract, but he had made experiments on this animal. He practised division of [illegible] of the spinal cord of the dorsal region, followed by later division of the anterior part, with electrical and other excitations to the sciatic nerve, the sensory reaction being determined by rise of blood-pressure. He found that the rise was often very great, even when the spinal cord was almost completely divided, which would favour the belief that there was a sensory tract in the periphery and anterior portion of the antero-lateral column.—Dr. G. N. PITT said that the column was known as Gowers' tract, and as such was described by Obersteiner of Vienna. There were variations in the shape of the tract. Whether the tract described in the fœtus by Dr. Sherrington and the above exactly correspond was a moot point. About the eighth month these ascending tracts began to develop, and the cutaneous functions of the skin also began to be exercised; was there any causal relation between the two occurrences?—Dr. HADDEN said that Dr. Bastian had described the tract many years ago, and his own case occurred later by one year than Dr. Gowers' description.—Dr. ORMEROD remarked that some cases of annular sclerosis might be attributed, not to degeneration of any special system, but rather to an extension of a meningitis.

Dr. SYDNEY JONES exhibited a large specimen of Tumour of the Palm of the Hand from a woman aged twenty-five, in whom it had been growing for eleven years. It reached from above the anterior annular ligament and encroached on the forefinger and the thumb, and also extended to the root of the middle finger. It was removed without much difficulty. It was composed of lobulated masses of soft fibromatous nature, and distinctly encapsuled. He had seen two tumours of the kind during the last year, but had never seen one so large as this. Large nervous cords pass around the pedicle of the tumour; but, with the exception of numbness of the middle finger, no nervous symptoms had resulted from the removal.

Mr. MAKINS showed specimens of Intra-bursal Fibroma. He considered that such growths originated in hypertrophy of the walls of bursæ and sheaths of tendons; also in thickening of the walls of ganglia formed by hernial protrusions of tendon sheaths. Specimens were shown of these growths (1) in the bursa patellæ; (2) in tendon of the biceps about the knee-joint, and from other parts. The sheath of the tendon of the middle finger was sometimes the situation of them. A papillary form of growth was frequently observed. Pedunculated forms of cartilaginous tumours were also of similar origin. Hypertrophied synovial fingers might be regarded as fibro-lipomata.—Mr. B. SUTTON considered that Mr. Makins had offered a true explanation of Mr. Jones's case—that it was a thickened ganglion. It was possible to trace transitions between inflammatory, fibromatous, and sarcomatous changes in bursal walls. In the Medico-Chirurgical Transactions he had described pedunculated bodies resulting from hypertrophied villi in knee-joint, shoulder, and ankle-joints. A "lipoma arborescens" was degenerated synovial villi.—Mr. H. T. BUTLIN doubted whether the explanation of Mr. Makins held good, for there was no tendon sheath that reached continuously from the finger to the annular ligament.—Mr. ROGER WILLIAMS joined in the discussion.

Mr. J. BLAND SUTTON described cases of Cysts in the neighbourhood of the Hyoid Bone. The first patient was a man who presented a tumour the size of a large walnut, occupying the floor of the mouth, bulging forward in the middle line. During the nine years he had noticed it he had submitted to seven operations. An anæsthetic was administered, and it was ascertained the cyst lay between the two genio-hyo-glossi muscles, and was so firmly attached to the hyoid bone as to need a raspatory to detach it. It was full of sebaceous matter, and contained a few hairs. The walls were composed of dense tissue, lined with squamous epithelium and dotted with sebaceous glands. The second patient was a woman, aged twenty-seven; the cyst in her case also was dermoid, and contained sebaceous material. Mr. Butlin, in his work on the tongue, inferred that these cysts were very rare. He spoke of about twenty recorded cases, but it is not difficult to find three times this number, for the cases described as sebaceous cysts of the tongue were really of the same nature as dermoids. Sebaceous cysts arising in the tongue, like those occurring beneath the deep cervical fascia, differed from those arising as a result of obstruction to the duct of a sebaceous gland. In branchial fissures incompletely obliterated, and in a persistent lingual duct, cavities lined with epithelium beset with sebaceous glands, which poured their secretion into the duct or persistent branchial space, existed. That

many of the so-called ranulæ arose from the lingual duct, and persistent portions of branchial fistulæ, was beyond doubt. The lingual and thyroid ducts might be detected in 10 per cent. of all bodies examined, and the thyroid duct in 15 per cent. Streckeisen found the latter duct and accessory thyroid cysts in about 25 per cent., but this might be accounted for by the facts that he obtained his material from a goitrous district. Mr. Sutton was induced, in part, to follow up the investigation, because Dr. Norman Moore stated before the Society that accessory thyroids were very rare. Many cystic tumours described as arising in the thyroid body really originated in accessory thyroid bodies and detached portions of the thyroid duct, and every transition might be traced from cysts lined with epithelium and filled with mucus to others containing papillary contents, of which a very beautiful example was exhibited last session by Mr. Bilton Pollard. The most aberrant examples, and at the same time the most malignant forms, were such cysts as Mr. Treves exhibited before at the last meeting. Cysts in the neighbourhood of the hyoid bone might be compared with cysts found in the ovary and its neighbourhood. 1. Cysts lined with epithelium, and filled with clear or mucoid fluid. 2. Cysts with papillary or villous processes projecting into their interiors. 3. Cysts with malignant carcinomatous growths sprouting from the walls. 4. Dermoid tumours.—Mr. H. T. BUTLIN could not concur entirely in the views expressed. There were cysts situated between the mylo-hyoid and the genio-hyo-glossus muscles, and nowhere near the middle line.

Mr. TREVES exhibited a specimen of Primary Melanotic Tumour of the Hard Palate from a woman aged fifty-eight, who was almost edentulous, and who for four years had worn a "false palate," which irritated the front and right side of the palate near the alveolus. In this region a tumour at first appeared of the size of a pea, but rapidly grew. When first seen it was a flat swelling covered by natural mucous membrane, but very black, or rather mottled, in appearance. There was severe pain. With chisel and mallet the portion of hard palate containing the tumour was successfully removed. It was a large spindle-celled sarcoma growing from the periosteum; recurrence of the growth took place after some months. The mucous membrane of the mouth of lower animals was much pigmented, and the present almost, if not quite, unique case seemed to indicate a reversion to a lower type.

Mr. BOWLBY (for Mr. Stephen Paget) showed Tumours of the Soft Palate. One from a man aged sixty; it easily shelled out, was well encapsuled, was a mixed-celled sarcoma, and contained embryonic muscular fibres and also tubular glands. The second tumour had a hyaline matrix with enbryonic cells and incipient tubular glands.

Dr. S. WEST showed a specimen of Acute Necrosis of the Fourth Cervical Vertebra from a man aged forty-eight. The disease began with pain in the shoulder, and this was followed by loss of power in the left hand. No cause could be discovered for the disease, unless it were a syphilitic affection of the periosteum. Later in the course of the case the left arm became completely paralysed and the right weak; still later there was complete paraplegia and a rapidly formed bedsore. The temperature rose to 108° before death.

The following card specimens were shown:—Mr. E. H. Fenwick: Calculus formed round an Umbrella Ring. Mr. Shattock: Parts after removal of the Ovary six months previously. Mr. Targett: Sarcoma removed from Sacral Region (recent).

MEDICAL SOCIETY OF LONDON.

The General Principles of Removal of the Uterine Appendages.

AN ordinary meeting of this Society was held on Monday last Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. LAWSON TAIT read a paper on the General Principles involved in the Operation of Removal of the Uterine Appendages. He took as his text the paper of Sir Spencer Wells in the *International Journal of Medical Sciences*. The number of operations to be performed must remain at present an unknown quantity. Nomenclature was the first general principle. He objected to the employment of the terms "spaying" and "castration." "The confusion resulting from faulty nomenclature was evident in Sir Spencer Wells's article, because he seems to assume that the removal of the uterine appendages has an argument against it in that it involves the non-production of the whole series of beings that might result from the subject of the operation." This could be no argument where the sterility of the woman is already frequently secured by the presence of serious disease. The mortality of the operation is not 14½ per cent., as stated by Sir Spencer Wells. The mortality in Mr. Tait's hands has only been 2 per cent. In cases of ovarian dysmenorrhœa and neuralgia, which have resisted all treatment, and in which life or reason is endangered, the operation should be limited or extended largely by the social position of the patients. In women who have to work for a living, it is impossible not to see the necessity of extending it to a much larger proportion of cases than in the upper ranks of life. For nervous excitement and madness, the operation, he agreed with Sir Spencer, was inadmissible except in certain cases of menstrual epilepsy. Of course the consequences should be explained to a sane patient. Mr. Tait said that Sir Spencer had completely misunderstood and confused the facts of his (Mr. Tait's) work. He considered that the diagnosis of the presence of irreparable disease in the ovaries was not only possible, but he had correctly performed it in hundreds of cases, dating from 1871. As showing the frequency of tubal disease, mention was made of four deaths from this cause in Queen Charlotte's Hospital, and these cases, during life, were regarded as puerperal fever. His earliest cases were for the purpose of relieving pain which was caused by diseased ovaries of small size, and was a departure from the principle, which had been maintained up to that time, that ovarian tumours ought not to be removed until they threatened life—a conclusion which could not be resisted with the high mortality which occurred in the practices of nearly all operators until 1878. After that the diminution in the mortality permitted the extension of old principles and the intervention of new ones. Such cases should not be called "oöphorectomy," or "castration," or "normal ovariotomy," or "Battey's operation," or any other name which does not mean that they were cases of removal of ovaries just as diseased as if they were the biggest cystomata which could be found in our lists.

The PRESIDENT congratulated the author on the lucidity and ability with which he had stated his case.

Dr. HALLIDAY CROOM thought it would be well if Mr. Lawson Tait would read a second paper on cases in which the operation should not be performed. He had a difficulty in knowing where to draw the line in the treatment of inflammatory disease. In some cases there was evidence of perimetritis and fixation of the appendages. In another class of cases the tube was inflamed and the ovary tender and a little displaced, and this in a young woman. Ought we in this second class to advise the removal of the appendages or to recommend simple, mental, physical, and sexual rest? He did not think it right that the patient should be allowed to decide the question for herself. He considered that these operations had been more frequent than they ought to have been. An imperfect diagnosis was one of the reasons for this. A bimanual examination should be made in all cases of doubtful diagnosis.

Mr. KNOWSLEY THORNTON said he was prepared to agree with the greater part of the paper. But even now the "general principles" were not fully stated. He could not accept the doctrine that removal of the tubes stops the menstruation. There was no evidence in support of this statement; and his own experience was decidedly opposed to that notion. In one case of pyosalpinx which he had treated surgically the patient menstruates regularly still. In other cases the menstruation ceased when both ovaries were removed and the tubes left. If the general title of "removal of uterine appendages" be applied to all such operations he thought there would result hopeless confusion. Are we to use this designation when but one tube or one ovary was removed? He did not think Mr. Tait's proposal would obtain a good nomenclature. He begged to say that he was not arguing against these operations, for he himself had practised them in a considerable number of cases with success. He believed that ovarian tumours occurred in far larger numbers than diseases of the tubes. Perhaps the latter were not more than one-sixth of the former in number. He doubted whether sterility was always secured in cases of tubal disease or ovarian disease before the operation was performed. In a case where he had removed two large dermoid tumours there was till the operation a fruitful ovary, for he operated whilst the patient was pregnant, and the healthy child of that pregnancy was still living. As to the four out of five deaths at Queen Charlotte's Hospital, it showed that

these patients were not sterile, for that hospital only admitted cases of midwifery. He asked whether sterile women died of puerperal fever. As to the mortality of this operation, 15 to 20 per cent. was more like the truth than 2 or 3 per cent. He had not practised this operation extensively, but had lost two cases out of fifty, or about 4 per cent. This mortality was an element not to be lost sight of. He believed in the occurrence of ovarian dysmenorrhœa, but the ovary was not necessarily bound down. Consultations were, he admitted, "farcical" sometimes, owing to the prejudice of some consultants. He could not believe that the operation was always a permanent and complete cure for uterine myoma; there was a certain number of failures. In one case three or four years elapsed, and then the woman began to bleed again.

Mr. C. E. JENNINGS related a case of Uterine Hæmorrhage to show that the bleeding might continue owing to the ovary not being completely removed.

Mr. ALBAN DORAN said that Dr. K. Fowler's observations published two years ago in the Medical Society's Transactions proved the frequency of occurrence of disease of the tubes. He hoped that the future of abdominal section would be directed towards watching the disease of the appendages with a view to curing their diseases rather than to removing the organs themselves. Until 1882 the disease which he described as papilloma of the tubes was almost completely ignored.

Dr. IMLACH considered that bimanual examination might sometimes be attended with pain and danger from the possibility of bursting a pyosalpinx or of causing an escape of the contents of the tube into the peritoneum. He considered that disease of the tubes was a more frequent cause of sterility than mere ovaritis. Hydrosalpinx was most frequent at the ages of thirty-five to forty-five, when the menstrual life was drawing to a close.

Dr. HEYWOOD SMITH thought a great deal of the bitterness of writers of leading articles arose from professional jealousy. He objected to the use of the designations "spaying" or "castration" to describe the operations. The prognosis of many cases was made different according to the social status of the patient. The rich could afford to be treated medically, but the poor would hail the operation as bringing speedy relief from pain and restoration to working life.

Dr. GRANVILLE BANTOCK argued on the meaning of the term "unsexed." It might mean that the patients would be incapable of bearing children as the result of the operation, or that they would be deprived of sexual desire and feeling. In acute diseases of the appendages the desire was almost always absent and frequently also in chronic disease. He agreed with Mr. Tait that "if in doubt open the abdomen" was the correct line of treatment. To curb the zeal of his too enthusiastic followers should be the aim of Mr. Tait.

Mr. LAWSON TAIT, in reply, said that Dr. Bantock had misrepresented him. The abdomen should be opened in cases of doubt only when there was risk to the life of the patient or when the patient was in a serious condition. As to bimanual examination, he urged that if the diagnosis could not be made with a skilled finger the operation should not be done. Ovulation and menstruation were not concurrent; he believed that the ovaries had relatively nothing to do with menstruation. As to the frequency of the diseases of the uterine appendages he could say nothing positively, but there seemed to be some grounds for believing that tubal disease was very frequent. Referring to the argument of Mr. Thornton relating to Queen Charlotte's Hospital, he urged that, the tube of one side being diseased, the patient was sterile on that side, and this incomplete sterility rendered the risk more serious, as, indeed, the four deaths showed. The mortality of an operation was not the mortality of a number of operators, but the mortality that the operation was capable of in the hands of experienced operators. He was sceptical of the existence of ovarian dysmenorrhœa, and believed that his operation was always a cure for uterine myoma, though the bleeding did sometimes continue a while after the operation.

ISLINGTON MEDICAL SOCIETY.

THE opening meeting of the Islington Medical Society took place, as usual, at the residence of W. Cattlin, Esq., Highbury-place. The chief feature of the proceedings was the narration of several cases of interest by Dr. Gilbart Smith. One was a case of very acute vertigo, in a boy of fourteen, following an interesting game of cricket on a hot day, two days before. There was great loss of power in the legs, so that he was found crawling, being unable to walk. He could not bear a pillow below his head on account of the giddiness. The pulse was 45; the heart sounds and the temperature normal. There was no vomiting, only slight frontal headache, and the optic discs were natural. For a month there was no improvement in the vertigo. But the later reports are that it is now, after a second month, on the decline. Dr. Smith thought that the symptoms pointed to some myelitis. Another of the cases was that of a medical man, who had albuminuria from gouty kidney and heart disease. On account of these symptoms he had some years ago relinquished practice, but underwent such improvement as to resume work. He did well until a short time since, when, after some excitement, he had a rigor, followed by pyrexia and pericarditis, with all the added distress of a dilated heart and aorta. The chief relief was obtained from very small hypodermic doses of strychnine and digitaline in solutions of uniform strength. The third case was one of alcoholic paralysis in a lady. The chief feature was some wrist-drop and weakness of the limbs; head always clear. A very important point in this case was that the alcohol was supplied by the *druggist*. In another case, also that of a lady, eau-de-cologne was the spirit taken.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on Oct. 8th, Dr. J. B. Bradbury, President, in the chair, the following communications were made:—

Removal of Depressed Fractured Bone of Skull.—Professor HUMPHRY showed a boy who had recovered after a severe injury to the skull. He was admitted into Addenbrooke's Hospital on August 23rd, suffering from a compound fracture of the frontal bone, the result of a kick from a horse twenty-four hours previously. There was a wound three inches in length and a fracture two inches in length, with a gutter depression. He was unconscious but could be roused. The depressed portion was removed, by sawing the contiguous bone with a Hey's saw and elevating the depressed bone. The dura mater was not injured. The boy appeared no better for the operation the next day, and only on the fourth or fifth day became conscious. Soon after he completely recovered. Professor Humphry commented on the great fluctuation in the treatment of injuries to the skull that had taken place during this century. In olden times the practice was always to trephine, and the patients almost all died. The tendency afterwards was not to trephine at all, and the results were more satisfactory. Recently, since the introduction of antiseptics, operative interference was more frequent, and the cases better selected. He thought the compression symptoms were due, not to the depressed bone, but to the injury to the brain at the time of the accident, and the removal of the depressed portion often appeared to give no immediate relief as in the above case, though it might prevent the onset of inflammatory affections from the irritation of sharp pieces of bone. He would advise operative interference in cases of compound fracture of the skull with depression, but not in simple fractures.

Incomplete Pericardial Sac; escape of Heart into Left Pleural Cavity.—Dr. BOXALL showed the chest organs of a woman who died with symptoms simulating pulmonary thrombosis on the third day after the birth of her third child. The necropsy, however, showed that a very peculiar accident had occurred. The pericardium on the left side was represented only by a sickle-shaped fold attached to the diaphragm and forming a pocket three-quarters of an inch deep. The heart was found lying in immediate contact with the lung, its apex being situated nearly three inches to the left of this pouch, from which it had evidently escaped during a severe attack of vomiting on the second day after delivery. This accident was followed by dyspnœa and collapse, in which the patient died thirty hours later.

Cancrum Oris.—Mr. WHERRY related a case of cancrum oris lately under his care in Addenbrooke's Hospital. A domestic servant, aged twenty-five years, had a deep ulcer filled with yellow slough, occupying the whole of the inside of the left cheek, said to have begun as a gumboil. The ulcer was almost painless. The skin of the left cheek was dusky red in colour over the slough, was nearly destroyed, and eventually there was a perforation through the cheek. The separation of the slough was at no time accompanied

by any hæmorrhage, there seemed to be no granulating surface to bleed, and there was only a thin watery discharge and faintly tinged saliva. Her complexion was remarkably pale-yellow and wax-like. The fever was high and the pulse rapid. The register on the chart was usually 104° to 105°, and the pulse 160 or more. She had been ailing four or five weeks, and had suffered from the ulcer two weeks before admission. No treatment was of any value in checking the progress of the malady, and she died exhausted in twelve days. She had always a good appetite, partook heartily of a liberal diet, and did not consider herself very ill. On two occasions operations were performed under ether. At first the slough was cleared out and the cavity left was swabbed freely with nitric acid. At a later stage the cheek was laid freely open from the outside. Quinine stopped the rigors which occurred occasionally. Iron was also given, and later on opium. Condy's fluid and insufflation of iodoform were tried locally. This patient was always pale and perhaps anæmic, but she was not ill-fed or ill-nourished, nor was she recovering from any acute fever. She had been able to do her duty as a domestic servant until attacked by the disease. Mr. Wherry briefly mentioned the reasons for making a difference between cancrum oris and other conditions somewhat similar, as ulcerative stomatitis. It was not a case of acute necrosis of the upper jaw. Though as yet no organism had been isolated from the blood or tissues, nor had the disease been inoculated, it seemed probable that in the future, as in the case of anthrax, a definite micro-organism would be discovered. In cancrum oris animals injected with the blood died of septicæmia, usually with peritonitis.—Mr. HEMMING (Kimbolton) described two interesting cases of anthrax contracted while cutting up a beast just killed, both patients recovered after injections about the slough with carbolic acid.—Sir GEORGE PAGET elicited that a dog and a cat died from eating of the entrails of this beast, but that a farmer, who begged for some of the meat, took it home, boiled it, and he and his family lived on it for a week and received no hurt. Sir George Paget considered that the micro-organism in the meat had been destroyed by the boiling.—Professor HUMPHRY described the ecchymosis in the skin and serous membranes found at the post-mortem examination of Mr. Wherry's patient, and agreed that death was probably from septicæmia.

THE REGISTRAR-GENERAL'S REPORT.

WE have received from Mr. Haviland copies of a correspondence, too long for publication in our columns, which he has had with the Home Office on the subject of the omission, from the supplement to the Registrar-General's report, of certain data which were given in the previous decennial supplements prepared by Dr. Farr. In the tables showing the mortality by certain causes Dr. Farr stated the deaths of males and females separately, while in the present report they are given for persons without distinction of sex. Mr. Haviland justly points out that by this arrangement a very important element in the study of the geographical distribution of disease is suppressed, as the relative male and female population varies considerably in different registration districts and at different ages. The bearing of this on any inquiry as to the relative healthiness of different localities is fully appreciated by Dr. Ogle, for he remarks, "It is necessary to point out that two places might be on a perfect equality with each other as regards their climate, their sanitary arrangements, their closeness of aggregation, as also the habits and occupations of their inhabitants, and yet might have very different general death-rates, owing to differences in the age and sex distribution of their respective populations.....It is unsafe, therefore, to base any comparison between two areas upon their general death-rates until it has been first ascertained that the populations of the two are practically identical as regards their age and sex distribution." But if it is unsafe to omit this element in any comparison of the general mortality of a town or district, how much more so must it be in the investigation of the death-rate arising from diseases which affect the two sexes in a markedly different degree? For instance, in the decennium now reported upon, in addition to deaths from childbirth, the following marked differences are shown by the returns for the whole population of England and Wales. The relative proportion of deaths of males and females respectively was—by cancer 32 and 62, by diseases of the urinary organs 52 and 27, of the generative organs 1 and 10, by suicide 11 and 3, and other violent deaths 101 and 33. It would certainly be interesting, and might be important from a preventive point of view, to trace how far these differences are general over the kingdom, or confined to particular districts, and if the latter, to endeavour to ascertain the causes to which they are probably due. But under the altered form of the returns this cannot be done. The reasons assigned by Dr. Ogle for the change are "not merely to economise space, but to give a broader, and therefore more secure, basis for the calculation of rates, and also to meet the practical requirements of the Medical Department of the Local Government Board." We own that we are unable to comprehend the last two reasons; for surely, if the whole of the deaths were included in the table, it would not narrow the basis to record the subdivision into male and female, nor do we think Dr. Buchanan would object to this additional information on the ground of its exceeding the requirements of his department. We are inclined to believe that the real difficulty has been raised by the officials at the Treasury on the score of expense. It looks very like one of those petty economies which sometimes are enforced, even at the risk of destroying really useful work. Considering that this supplement is only brought out once in ten years, we do not think it could be characterised as extravagance if the detailed tables were published in the form originally adopted by Dr. Farr. Such a course would have the advantage of providing "a broader and more secure basis for the calculation of rates," by enabling the results of each succeeding decennium to be added to those of preceding periods. Dr. Ogle is so well aware of the important bearing of age and sex distribution upon statistical inquiries, that we feel well assured the change was not made on his recommendation, but was much more probably introduced in opposition to his wishes.

THE HOURS OF SHOP ASSISTANTS.

THE Shop Hours' Regulation Bill has at last become law. By extending to young persons employed in shops the benefits of a fixed work period enjoyed by their more fortunate companions in factories, it will do something to check the evil of heedless over-pressure, which has already told with disastrous effect against the class of shop servers. Being fully cognisant of this effect in our professional capacity we view with much approval, if we cannot yet say with full satisfaction, the passing of a measure of such proved necessity, even though to our regret it comes as an example of paternal legislation. Objections to the Bill continue to be urged by those who regard it as a superfluous measure. Pictures are drawn of shops in which trade is slumbering or moves easily on a semi-domestic system which needs no regulation, of the impossibility of inspection or of any benefit without this, of the banishment of young persons from behind the counters in favour of their elders, who have no means of retreat from overwork, and of the tyranny and ruin implied in a general reduction of the hours of service. On the other hand, we might urge with greater force the fact that easy situations do but caricature the worry and hurry which prevail in the shops of many city thoroughfares, and it is for such that this Bill is intended, while the supposed injustice and oppression of a general earlier closing are more than equalled in the actual, if not evident, compulsion which an employer can under present conditions exert if he chooses upon his dependants. If we should say anything in criticism of the Bill, it would be that it does not go far enough. We have no wish to under-estimate the difficulties of the State in dealing with the question of adult labour. At the same time we cannot but see that to fix the limit of supervision at eighteen years of age is to leave absolutely without such protection as they require a large number of persons of all ages, whose well-being, all things considered, may be a matter of even greater consequence than that of their juniors. We are loth to believe that inspection cannot be applied in the interest of shop *employés*. How any Bill can be administered without some machinery of supervision is not very clear, and we cannot but express once more the hope that means directed towards this end will yet come to find their legal expression within the terms of the Act.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 6, 1886.

THE position which the Royal College of Physicians has taken up with regard to the requisition of the Apothecaries' Society for permission to enter into combination is, we believe, one of *non possumus*. There can be little doubt that the Royal College of Surgeons will answer in practically similar terms. The Conjoint Examining Board is considered to be complete, and nothing further to be necessary so far as they are concerned. Should the petition for admission into a joint combination with the Colleges be refused, the next question that arises is, What can the Apothecaries' Society further do? It cannot at present grant a statutory diploma in surgery, as it can in medicine and midwifery, although it examines in all three subjects, and has done so for the last few years. It can only practically grant a medical, as distinguished from a surgical, qualification, just as the Royal College of Surgeons, although also examining in three subjects, has occupied the converse position. The Apothecaries' Society must, in order to give a complete qualification under the terms of the recent Medical Act, combine for purposes of examination with a body legally qualified to grant a diploma in surgery, just as the College of Surgeons has formed a Conjoint Examining Board with the College of Physicians. A refusal on the part of the Colleges to admit the Apothecaries' Society to conjoint action will drive the latter to appeal to the Universities, and there can be no doubt as to the nature of the reply that will be given to such a petition. The University of London and the Royal University of Ireland are the only Universities that do not require residence, but their insistence on the highest possible professional standard is so notorious that the suggestion that the Apothecaries' Society should be allowed to flourish under their wing could hardly be entertained. The General Medical Council is the next body to which appeal can be made, and it may appoint, if "it shall think fit," assistant examiners, and on such appointment the qualification becomes duly registrable as a complete licence in medicine, midwifery, and surgery. We presume that such examiners will be well-known surgeons, and this will probably be the termination of the difficulty, for we question if the Colleges or Universities will give way or the Society be allowed to undergo a sudden extinction. But should the General Medical Council refuse to come to the assistance of the Society, a further appeal to the Privy Council is provided for, and, from the words of Sir LYON PLAYFAIR previously to the passing of the recent Medical Act, there can be but little doubt that the Government will see to its perpetuation as a qualifying body, and that the conditions for its existence will be forthcoming. Are the Colleges therefore wise in ignoring the claims of the Apothecaries to be admitted to a Conjoint Board, when it is almost certain that the Hall will still remain as an institution, venerated by many practitioners, and that it will be still able to grant a registrable diploma in all branches of practice? So far as a mere examining board is concerned, it is obvious that no strength can accrue to the authorities responsible for the present conjoint scheme by admitting the Apothecaries' Society into combination. The only reason, and it is a very powerful one, for urging the Colleges to weigh carefully their decision, is that the Apothecaries' Society under their Acts of 1815 and 1874 have the power of prosecuting illegal practitioners, and this is too important a function to be lightly passed over. Such a power cannot be dispensed with in any profession—the Incorporated Law Society discharges this function for the legal profession,—and the Apothecaries' Company deserves every thanks for exercising it, if somewhat sparingly, at least wisely and judiciously, and to the benefit of the community as well as of the profession. This power surely ought to have been invested in the General Medical Council by the Act of 1886, in accordance with the reasonable dictum that responsibility and authority should have been put side by side with direct representation, and then the question of the future of the Apothecaries' Society would have been determined on its status and position as an examining body. But this is now impossible, and it is only one of the many blots and shortcomings in this hasty and incomplete measure which we pointed out when it was being considered in Parliament. We shall now probably see, as a result of the Act, the initiation of two grades of practitioners in England—one consisting of graduates of Universities and those who hold the diplomas of the Colleges, and the other of the licentiates of the Apothecaries' Society only; and as regards the welfare of the medical profession the existence of another complete, but necessarily lower, qualification must be looked at as a very serious question in the future.

IT is to be hoped that the action which the Government have taken with regard to the troopship *Euphrates* may constitute the beginning of the end of the attempts to impose measures of quarantine on vessels passing from India to this country by means of the Suez Canal. We announced last week that four deaths from cholera had taken place on board the troopship before her arrival at Perim, at the mouth of the Red Sea, and it remained to be seen whether the Alexandria Board of Health would allow the vessel to proceed into the Mediterranean without touching anywhere on her way, or whether attempts would be made to carry out the usual system of quarantine with all its attendant fees and rewards. The free passage of the Canal was refused, and the vessel with its human freight of some thousand souls was ordered to return over a hundred miles down the Red Sea to El Tor, where a quarantine establishment is supposed to exist. But as a matter of fact there is at El Tor nothing resembling a proper quarantine station. The place is unhealthy, only a few huts are available, and the commonest decencies of life are wanting. To land a thousand men, women, and children there under such circumstances would be one of the very best methods of bringing about disease and death. In fact, last year the director of the establishment was himself obliged to urge his superiors not to require the landing of the crew and passengers from a French transport, and this on the ground that such a proceeding could only aggravate disease and lead to mischief. In view of these considerations, the British Government

took a step which, if followed out, must have an important influence in getting rid of this quarantine system along the line of traffic between Europe and our possessions in the East. They refused to allow the *Euphrates* to be sent to El Tor, and they announced that unless she were permitted to pass through the Canal she would be ordered to come home by the Cape route. It is well known that money considerations have always had much to do with these detentions in the Red Sea, and it has more than once been a question whether Great Britain would not do better to build a special class of troopships capable of fast sailing and to resume the Cape route, rather than run the risk of obstructive delays with her troops in the Red Sea. But hitherto the matter has only amounted to a suggestion, resort to the alternative route never having been actually entertained. The threat, however, had an immediate effect. Shipping dues, Canal dues, quarantine fees, and all sorts of expenditure by which numberless people profit, would come to an end if Great Britain really carried out her intention, and hence permission was at once granted for the *Euphrates* to pass through the Canal, provided the vessel was first submitted to a so-called process of disinfection, which, as everyone knows, can only be a mere form in the case of a ship which is occupied by crew and passengers.

When the demand for the free passage in quarantine of the Canal was made at the Rome Conference by Sir GUYER HUNTER on behalf of the British delegation, support came from an unexpected quarter, for the Egyptian delegate handed in a document in which he declared that the quarantine establishments in the Red Sea were altogether mythical in so far as efficiency was concerned, that the passage of the Canal in quarantine could be made without any danger to Egypt, and that it was, in point of fact, the only solution of the difficulty. But the French delegation, pretending that they were not satisfied that the sanitary condition of this country sufficed for the protection of the Continent, declared that if England were once infected she would constitute a source of danger to Europe, and hence that British vessels, not touching elsewhere, were not even to be allowed to pass direct to this country. It was pointed out by Dr. THORNE THORNE that such a spread of cholera to Europe was purely hypothetical, and that, as a matter of fact, cholera had never taken such a course; but the desire for maintaining quarantine was too strong, and the very passage which has now been granted in the case of an infected vessel, such as the *Euphrates*, was denied. In short, the pecuniary consideration has wrought more than any number of scientific discussions could have brought about.

It remains to be seen how far the case of the *Euphrates* can be regarded as a precedent for action on the part of the British Government. We have yet to learn the medical history of the crew and troops on board, and it may be that if at the moment when the vessel was allowed to enter the Canal there were no actual cases of cholera on board, the precedent may be regarded by the Egyptian Board as not covering the case of a vessel having actual disease amongst her passengers. But it is to be hoped that, whether there be disease present or not, our Government will never again consent to allow the crew and passengers of a Government ship to be landed in a swampy, unhealthy spot, where no proper provision is made for their reception and treatment, simply to please communities who decline to make their ports healthy, and hence want all disease and all risk of infection dealt with, for their protection, on the unhealthy shores of a distant tropical sea.

THE Hawaiian Legislature has recently issued a report on Leprosy presented them by the Board of Health, accompanied by a supplement and an appendix containing extracts from official reports and records, which are of great interest in enabling us to follow the steps taken at such enormous cost (10 per cent. of the whole revenue in 1884) to try to control the progress of the disease in the Hawaiian Islands. The Board also issued in 1885 to foreign governments a circular letter and the questions prepared in 1862 by a committee of the Royal College of Physicians of London, and they have summarised the answers in a further report to the Legislature.

According to Dr. HILLEBRAND, leprosy was introduced into the island of Oahu by the Chinese in 1848, and he saw the first Hawaiian leper in 1853. Ten years later he called the attention of the authorities to the prevalence of what the natives called "Mai Pake," or the Chinese disease, in which he recognised leprosy. Whether this disease really was introduced by the Chinese, and perhaps other immigrants, and propagated from Oahu with rapidity over the other islands, or whether it was an heirloom which the Hawaiian race brought with them to these parts, and which had escaped much recognition since the landing of the first American missionary in 1820, is a very debatable point, but evidence is now forthcoming to show that cases of leprosy were seen on the islands before the date of Dr. HILLEBRAND'S Chinaman. Directly, however, attention was drawn to the facts the public mind became greatly agitated, and it was believed that a sudden development of leprosy had taken place and that a rapid spread was going on. When means of relief were offered and a search was made, an enormous amount of disease was disclosed. The Law of Segregation was enacted in 1865, and the Kalihi Leper Hospital established on the island of Oahu, near Honolulu, in which a sure diagnosis might be made and incipient cases treated, whilst incurable and dangerous lepers were isolated on the special settlement (now about 5000 acres in extent) so often described, on the northern side of the island of Molokai. The Kalihi Hospital was abolished in 1875, but in 1881 it was considered advisable to build one for very similar purposes at Kakaako, near Honolulu, and in 1884 like institutions were projected in each island of the group. From time to time the Board of Health was encouraged in the hope that its efforts were rapidly stamping out the disease, but each time it was disappointed, as a more vigorous search by increasingly experienced officials and perfected methods disclosed the continued great prevalence of the disease in all the islands. Dr. EMERSON wrote in 1879, after a medical inspection, that leprosy was deeply rooted in the declining native population, and it was calculated in 1882 by the best authorities that from 4 to 5 per cent. of the whole native population of 40,000 people suffered from it. Throughout, the application of the law has been imperfect and spasmodic, and has necessarily given rise incessantly to great hardship and heart-

rending scenes, such as may be easily imagined from the breaking up of homes and separation of relatives and friends. There are insuperable monetary and other difficulties to the merciless and rigid enforcement of the law, and it has been found impossible to segregate all the lepers, so that the desired progress must be slow, and indeed it must be confessed that after twenty years it is but little apparent. As Dr. MOURITZ points out, the great drawback lies in the fact that the leprosy is not shunned by the Hawaiian until the later loathsome stages have set in and the sufferer has become a burden to the family, and that there is not that social ostracism practised whereby in many countries the progress of the disease is checked. Meanwhile lepers live in unrestricted intimacy with their families until surrendered to the authorities in the later stages, and it appears that in 1884, in 90 per cent. of the lepers segregated the disease was of several years' standing. A periodical examination of the schools should be carried out, for Dr. ARNING found 7·27 per cent. of early leprosy in two schools in Honolulu, and the detection by the same physician of many bad cases in remote gulches and corners where few white men penetrate would seem to show that much remains to be done in the systematic examination of the islands. So far 3076 lepers have been received on the Molokai settlement in the twenty years of its existence, and there have been about 700 living there annually in recent years. The history of this settlement, and of the immense difficulties encountered, and at last, we are glad to say, in great measure surmounted, is full of interest and instruction to other countries, and we heartily congratulate all concerned on the immense progress made in ameliorating the lot of the unfortunate beings doomed to eke out their existence on a spot so remarkable for its natural features, and the use to which it has been put by the Hawaiian Legislature.

IN an article which we published last June we evidently gave great offence to the *Australasian Medical Gazette*. We need hardly explain that we had no intention of saying anything at which our contemporary could take umbrage, and we do not think that our comments merit the condemnation they have received. We commented adversely on the action taken by the Government of Queensland in the case of the emigrant ships *Dorunda* and *Quetta* with a view to prevent the importation of cholera into the colony. For this, however, we are not taken to task. But we are blamed for the suggestion that Australasia would do well to adopt our system of medical inspection and isolation instead of the modified quarantine which is at present relied on; and we are reminded of the various points, climatic and other, in which Great Britain differs from the colony, and which justify resort to quarantine in Australia, although the alternative system is admitted to be the best one for ourselves. With some of the points referred to we cannot agree. Thus, it is stated that though physically Great Britain is an island, yet epidemiologically she is a part of the continent of Europe. This, in so far as cholera is concerned, is hardly correct. We believe our greatest danger from cholera comes from India and the Red Sea; and it is matter of notoriety that when England has suffered from invasion of that disease, the infection has come to us, after a somewhat lengthened [illegible] by of the Baltic and the Mediterranean, and not from those countries which lie near to us in the west of Europe. But we are willing to admit that our circumstances and those of Australasia do differ in some important respects, and that action as regards cholera which would only be fraught with mischief if it were applied to this country might be practicable and in some sense justifiable in the colony. Still, there is one consideration which, in our opinion, outweighs all others—namely, the fatal influence which trust in quarantine restrictions has upon the progress of measures which tend to the improvement of public health. The mere fact that communities are promised by their Governments that they will be protected against the importation of such diseases as cholera by quarantine measures has almost invariably had a very deterrent effect on expenditure and works aimed at the removal of those conditions, the existence of which alone makes the importation one to be dreaded; and although, as we are reminded by our contemporary, our internal sanitary administration is still the reverse of perfect, yet we know, as a matter of fact, that had it not been for the knowledge that our Government would make no pretence of guaranteeing safety by quarantine measures, the vast improvements which in this country have been effected when cholera has appeared as a prospective or immediate danger would never have been carried out. And, after all, cholera is not the only, or indeed the main, disease to be dreaded. Enteric fever, for example, causes needless mortality in Australia as well as in England, and whereas quarantine restrictions cannot be expected to assist in eradicating that fever, yet one of the most striking reductions in the mortality of this kingdom which has resulted from sanitary measures initiated by a dread of cholera is that of this fever, which, above all others, kills at the most remunerative period of human life. In short, the system we have been compelled to fall back upon in regard to imported infections, because of the impracticability of quarantine, has done more to reduce our mortality from general causes, and especially from preventable diseases, than any other. This is a consideration which, we venture to submit, no community should disregard.

The parallel drawn by our contemporary between the attempted quarantine detention of sick and healthy alike at Leicester when small-pox occurs, and the proceedings adopted as to quarantine in Australasia, is hardly an apt one. In the Leicester case the law is defied, and those in authority refuse to carry out an all but unfailing method of disease prevention, and then attempts by resort to measures of detention which we believe to be illegal to make up for their default. Such a system courts failure, for it would only require a refusal on the part of the hitherto healthy to submit to a detention which there is no means of enforcing, in order to bring the whole scheme into sudden disrepute. Besides which, the Government of the country not only does not encourage such detentions, but it declares them to be altogether illegal. In this case the healthy have a well-recognised and all but certain means of staving off disease; and hence our Government does all it can to discourage resort to other means, which are not only less certain in their influence, but which fail to effect the indirect good which comes of adopting the proper remedy. "Some day," says

our contemporary, "the English system will be the best for all the world." After all, then, we only differ as to the proper date for its application; our view being that Australia would benefit from the system even at this comparatively early date in its commercial and sanitary history. In this country we erred by delaying its application, and we have suffered in consequence.

THE approaching session of the Medical Council ought to be interesting, as being its last meeting without the presence of direct representatives of the profession which it is supposed to rule and represent. Looking at the matter from an outside point of view, it would seem as if there were nothing to justify the meeting of the Council till it shall have been made more complete by the addition of the direct representatives. But this may be a wrong conclusion, and we shall be prepared for any good and sound work that may be reported as accomplished or in progress. We can only guess at some of the business that is likely to engage the attention of the General Council. It may be remembered that at its last meeting the Council was much occupied in the discussion of the Reports of the Visitors to the Universities of the United Kingdom. These reports were of a valuable and interesting character, and excited questions of much moment. They occupied so much of the attention of the Council that the discussion of other matters had to stand over. One of these other matters was the *consideration of Reports from the Branch Council on a system of Visitation of Examinations for the year 1887*. It might be thought that one of the principal reasons for the impending meeting of the Council was the consideration of these reports. But we can scarcely think this will be so, for one simple reason. The new Act enjoins a new method on the Council for acquainting itself with the efficiency or otherwise of examinations. Hitherto the Council has had only one way of doing this—viz., by a System of Visitation. At first, the members of the Council representing one examining body in each division of the kingdom went to visit another in the same division, and then the visit was reversed. A little advance was made on this primitive and suave method of visiting, by sending the representatives of a body in one part of the United Kingdom to visit a corporation or university in another division. But obviously this was not satisfactory. There was, if not a tendency to mutual admiration, at least a sense of fellow-feeling and fellow-fear. The representatives of different divisions of the kingdom were still members of one common body, tempted to be to each other's faults a little blind, and to their virtues very kind. An improvement on this system of visitation was introduced by appointing gentlemen of high standing and experience as teachers and examiners from the outside, and associating them in the visitations with the members of the Council.

The new Act provides a different way of ascertaining the sufficiency of the qualifying examinations. Section 3, Clause 2, requires for this end the appointment of a sufficient number of Inspectors, "*to attend, as the General Council may direct, at all or any of the qualifying examinations held by any of the bodies.*" We cannot suppose that such an important provision of the new Act will be put in force before the completion of the Council under the same Act; and obviously the discussion of any elaborate schemes of visitation formulated before the passing of the new Act would be a waste of time.

Another important decision of the Medical Council at its last meeting was to visit and report on the Medical Schools, with the permission of the said schools. It is possible that Clause 3 of Section 3, referring to the appointment of inspectors, may be considered to give the Council new powers of inquiry into the efficiency of schools; but even so, it seems to us that this question, too, ought to stand over till 1887, when the direct representatives come into office.

One thing we gather from the Minutes—that we may expect the report of the completion of the work of the Statistical Committee, upon which an enormous amount of labour must have been expended. We shall look to the final results with much interest. The state of the Register may fitly engage the anxious consideration of the Council. The attention of outsiders has been much drawn to it and to its many imperfections during the recent months, and in connexion with the new Act and the impending elections. It is evident that the system hitherto pursued of occasional and promiscuous inquiry under Section 14 of the Act of 1858 does not give us anything like such a correct Register as we ought to have. A shrewd lawyer has recently estimated that there may be 2000 errors in the Register! This, with such large unused sums of money in the hands of the Council, is most unsatisfactory, and ought to exercise the ingenuity of the Council. There is a want, too, of readiness in printing the Register and additions to it—a want, we cannot think of disposition, but of ready ability to meet the real need of the profession. One fact will suffice as an illustration. For the purposes of the impending election it is of great moment to get the addresses of those registered since the present Register was published. It will scarcely be credited that a printed list of these names cannot be had "for love or money." An advertisement in our present number shows that nearly the whole of the members of the Medical Services have no addresses so far as the Register is concerned, and are not to be reached by anxious candidates. An attempt is to be made to get them at the eleventh hour, but it is too late.

Finally, the new law regarding the Recognition of Foreign and Colonial Degrees will require the early attention of the Council. But it is highly desirable that there should be no haste in this matter, and that time should be taken to gather necessary information.

Annotations.

"Ne quid nimis."

COMPULSORY ATTENDANCE AFTER REJECTION AT EXAMINATION.

ONE of the most harmful proceedings on the part of the Conjoint Examining Board in England has been to re-examine rejected candidates without the production of further certificates from the teachers in the subjects in which they had been previously rejected. The College of Surgeons, when acting alone, had always insisted that a candidate who had been referred should, on presenting himself for [illegible] proper evidence

that he had been engaged in the interim in studying the subjects in which he had previously failed to pass; but under the regulations of the Conjoint Board this wise proviso has been dropped. Candidates who had once gained their certificates were signed up for ever. The only limit to their presenting themselves over and over again was the elasticity of the purse of their parents and guardians, and students have been re-examined quarterly and half-yearly for two or three years on one certificate. As a rule, their knowledge, incomplete as it was at first, grew gradually less and less, and time that should have been devoted to anatomical and physiological studies, or to medical, surgical, and obstetric practice, as the case might be, was spent in general idleness, without the possibility of any interference on the part of the authorities of the school, who were generally blamed by the parents, whilst the fault rested entirely with the Conjoint Examining Board. This was pointed out in very explicit terms in our Students' Number, and we are glad to find that the Committee of Management for the Conjoint Examining Board has recognised the necessity of insisting on a further course of study by rejected candidates under their authorised teachers, and that the regulations recommended by it, and printed in our last number, in the Proceedings of the Royal College of Physicians, will do something to prevent the demoralising effect on the discipline of the medical schools which this unfortunate omission is answerable for in the past three or four years.

SLEEPING IN TURKISH BATHS.

FEW general assertions are particularly true. We cannot endorse the statement that it is wrong to sleep in a heated atmosphere like that of a Turkish bath, just as we are unable to adopt the opinion that the Turks generally are "indolent." It is doubtless "a most dangerous proceeding" for the subject, or victim, of what is, or was, popularly called a "carouse," by which is generally signified a debauch of heavy drinking, to lie down and sleep off the effects of his intoxicating and exhausting excess in an atmosphere and under conditions which will draw blood rapidly to the surface, and thus to some extent deprive the heart of its natural stimulant, if the person so acting have a weak heart. The heart's action will have been quickened by the hot air, and exhaustion may supervene at the moment when determination to the surface occurs. There can be no question that cases of submersion or "drowning" may end fatally because the unfortunate victims are plunged into warm baths which determine the blood to the surface and leave the exhausted heart without proper support or stimulus. We admit all this; but it does not follow, thereupon, that sleeping in the average atmosphere of a Turkish bath is dangerous to average mortals. On the contrary, we are of opinion that a "nap" taken under such conditions, not too prolonged, is both refreshing and restorative. The mistake frequenters of Turkish baths commonly make is that of staying too long in the "hot room." As a matter of fact, it is neither necessary nor safe to raise the temperature of any room in a Turkish bath above 140° F., and no bather should remain in a room heated to above 120° for more than a very few minutes. There can be no worse practice than to go into a highly heated room until *after* perspiration has commenced. Thus acceleration of the heart's action, which is likely to be followed by exhaustion, does not occur if the bather is content to wait in a room of low temperature until after the skin has commenced to act. Practically, the following rules may be taken as safe and sufficient for the guidance of those who use the Turkish bath for restorative purposes, and particularly the many who, suffering from sleeplessness and brain worry in these days of high pressure, seek, and generally find, comfort and refreshment in that relaxation and repose which the hot-air bath, when properly ventilated, is sure to afford. 1. Go at first into one of the least heated rooms, with a temperature very little above blood-heat (or, say, not much over 100° to 110°), and remain there until the surface of the body is moist and slightly reddened. 2. If the skin does not become warm and begin to grow red and moist in ten minutes, ask one of the shampooers to affuse the surface with *warm* water, and to rub it briskly and lightly with a soft towel. Then return to the apartment where the temperature is not much above 100°, and wait until perspiration is established. 3. When perspiration has fairly commenced, and the surface is moist from head to foot (not before), have a little cold water thrown on the feet and legs, and then go into a room of somewhat higher temperature, but do *not*, on any account, enter a part of the bath where the heat registered by the thermometer is more than 140° F. This is very important. 4. Either lie down on a couch or sit while in the bath, and, if not disagreeable to do so, keep the eyes closed as much as possible. 5. Do not remain in any of the hot rooms longer than half an hour; not so long if the ventilation be imperfect or the air impure. 6. Ask the shampooer to "finish" with an affusion of gradually cooled water, not cooler than is pleasant. Do not either take the plunge bath or receive the douche. This direction is especially for those who are not sure as to their organic state, and points to a necessary precaution in cases of weak heart or exhausted nervous system. 7. Drink nothing but iced water, potass- or soda-water, or lemonade, while in the bath. Take a small cup of coffee or tea when in the cooling room, and lie down, or remain sitting, wrapped in towels, until the perspiration has subsided, but not long enough to feel cold. Then dry the skin with a rough towel, rubbing briskly, and dress quickly. 8. A short walk is desirable after the bath, and soon afterwards a light meal, with pleasant conversation and cheerful surroundings; but the exercise taken, whether physical or mental, for some hours after the bath should be very moderate, and worrying work of any kind ought to be avoided. These are general directions, and may be modified in special cases, but they will apply to the multitude of bathers by whom the bath is used as a measure of relief and restoration after brain toil, and in mental and muscular weariness.

ANTIPYRIN AND ANTIFEBRIN.

AT the meeting of the Verein für innere Medicin at Berlin on the 18th ult. Dr. A. Fränkel read a paper upon Antipyrin (see *Münchener Med. Wochensch.*, Oct. 26th), especially in the treatment of acute rheumatism. Having prescribed it in thirty-four cases of this disease he arrives at the conclusion, supported by the published observations of Lenhartz and Alexander, that its action is that of a specific. Rapid recovery ensued on its administration in nine out of thirteen mild cases and in four out of twenty-one severe cases. It is superior to salicyl compounds; first, in the readiness of administration, being given in the amount of 15 grammes during the first three days and of 3 grammes daily during the next six days; and, secondly, in the freedom from unpleasant physiological effects. He only once noted vomiting after antipyrin, and twice an "antipyrin rash" appeared. Free sweating occurs with the defervescence produced. Respecting protection from endocarditis he is unable to pronounce from paucity of material, but some authors think this must be answered in the negative. Nor can it absolutely replace other anti-rheumatic remedies; for in two cases it had no effect and in fifteen cases there was relapse. He did not know of any contra-indications to its employment, and summed up to the effect that antipyrin is an energetic specific anti-rheumatic agent; that its trifling phy-

siological effects make it important to prescribe it at first in every case of acute articular rheumatism, but that it is no substitute for salicylic acid, some cases reacting to the one drug and some to the other. Dr. Fränkel also reported on antifebrin, introduced by the Strasburg school—a substance of exceptional interest, since in chemical composition it differs from any other known antipyretic. It is derived from aniline, is an odourless powder, slightly soluble in water, but readily dissolving on the addition of rectified spirit. It produces slight toxic effects, does not induce vomiting, and is not repugnant to take. In hourly doses of 0·1 gramme it causes a transient fall in temperature of from 3° to 4° C. Dr. Paul Guttmann, in discussing the paper, remarked that of 18 cases of acute rheumatism treated with antipyrin the average duration was 25 days, and of 67 treated with salicylic acid, 35·2 days.

THE SANITARY STATE OF WEST COWES.

THE sanitary state of West Cowes has been prominently brought before the public on more than one occasion, and owing to the allegation that diphtheria was prevalent there, Mr. Spear was recently instructed by the Local Government Board to make inquiry into the matter. On arrival he was officially informed that the townspeople doubted the existence of diphtheria, but he soon found seven well-marked unequivocal cases in four different families, all the cases exhibiting the typical fibrinous exudation in the fauces, fever, and albuminuria. This disposes of the denials as to the existence of the disease. Later on a total of seventeen unequivocal attacks, one of which had proved fatal, and four doubtful attacks were heard of. In discussing the causes of this prevalence, Mr. Spear states that considerable suspicion attached to the milk service, for each of the infected households in the first series of cases was found to be receiving milk from one and the same dairyman. There were points which went to reduce the significance of this fact, but both Mr. Spear and the medical officer of health could not but regard the association of the milk distribution with the incidence of the disease as of significance, and this, although nothing could be detected by which the milk-supply could have become contaminated. But the 1886 outbreak in West Cowes was not a singular occurrence. In 1885 the district suffered severely from the same disease, and no less than seventeen deaths were recorded from it, forming a rate of mortality more than ten times the corresponding average rate for England and Wales; and having regard to this fact, it becomes possible that, in some degree, a retention of the poison may have been a cause of the recurrence of the disease. Our information as to the etiology of diphtheria is still so imperfect that no sanitary authority could be regarded as to blame for such a recurrence, provided they had taken care to remove from their midst the defective circumstances with which the disease is so often found to be associated. But, unfortunately, this proviso by no means applies to the case of West Cowes, for so common were defects leading to excremental pollution of the atmosphere of the town and of individual houses that the facts justified the conclusion that these conditions were largely associated with the outbreak. Retention of foul black deposit in sewers, scanty and most imperfect ventilation of a tide-locked culvert half a mile in length, a universal absence of proper sewer ventilation, offensive emanations from street gullies, defective construction and ventilation of house-drains, and danger to the public water service; these are the conditions which were found to obtain in West Cowes, with its well-known narrow thoroughfares, in which there is a considerable amount of overcrowding of houses. Then, again, in the new part of the town we read of badly constructed and overflowing cesspools; and as to the general disposal of the sewage, it is stated to be a source of nuisance. At last we learn that the sanitary authority have called in a consulting engineer to advise on the state of the sewers, but we cannot forget that as far back as 1879 the local medical officer of health found the public drains "nearly all in a bad state," that in 1880 he drew the attention of the authority to the defective state of the sewers and that Dr. Ballard and Mr. S. J. Smith, C.E., have visited the district on behalf of the Local Government Board. In the face of such a record, it is useless for those representing the authority to publish statistics based on a supposed population, and tending to show that the general mortality is small, or to point to the fact that they have been by no means inactive. What the public will want to know before this hitherto favourite seaside resort has its credit restored is, whether the sanitary authority have efficiently dealt with obvious sources of danger to health to which their attention has for some years past been directed, and which in 1885 and again in 1886 were associated with the fatal spread of a disease which is largely preventable by the adoption of ordinary and well-known sanitary measures.

RELATIONSHIP BETWEEN HYALINE AND AMYLOID DEGENERATION.

DR. STILLING, of Strasburg, has demonstrated (Virchow's *Archiv*, vol. i., p. 103) that hyaline degeneration may merge into that of amyloid degeneration. His observations were made chiefly on the spleen, as the organ which earliest undergoes waxy changes, the object being to show that in recent cases of amyloid degeneration areas of hyaline change are also present. In a case of phthisis, of which full details are given, this combination was well marked, and the hyaline product mixed with amyloid was also found in other cases of acute and chronic disease, though always of the same class—viz., chronic inflammation of bone and joints, and in tuberculous disease of the lungs; the hyaline change being more predominant than the amyloid in cases of short duration. In one case the spleen appeared to be amyloid throughout, but on applying the characteristic tests it was proved to be altogether hyaline. It is interesting, in relation to these observations, to remember that so long ago as 1879 this connexion between hyaline and amyloid degeneration was pointed out by Dr. Stephen Mackenzie and Dr. Ralfe in the debate of that year at the Pathological Society on lardaceous disease. Dr. Mackenzie, speaking with reference to the influence of fever in producing lardaceous disease, called attention to the changes in bloodvessels that occurred in certain diseases with blood alterations—a change which consisted of a hyaline transformation, which did not give a characteristic reaction with iodine, but stained slightly with methylaniline violet. Dr. Mackenzie did not regard this hyaline material as lardaceous, but, as it occurred in diseases attended by alterations in the blood and most of them febrile in character, he thought an investigation into the nature of the hyaline change might throw some light upon the origin of lardaceous disease. Dr. Ralfe, speaking with reference to the same subject, thought the difference between hyaline and waxy degeneration was one only of degree, the hyaline being the first step in the degenerative process. He has further stated that a microscopic examination of the hyaline substance shows at first that it consists of granules of an albuminous character, which are insoluble in ether; but at a more advanced stage these granules become distinctly fatty and soluble in ether. From this he argues that the hyaline changes are the first step in a process, which, if acute, leads to fatty degeneration; if chronic, to lardaceous degeneration. Though the extensive and elaborate researches [illegible] have now established the

fact of the connexion between hyaline and lardaceous degeneration, it must not be forgotten that the suggestion first came from England.

YELLOW FEVER INOCULATION BY ONE OF THE PROTECTED.

DR. R. ISSARTIER, surgeon in the Messageries Maritimes, who has submitted himself to Dr. Freire's anti-yellow fever inoculation, describes in the *Journal de Médecine de Bordeaux* he observations and experiments of the Brazilian professor. The microbe found in all the fluids of persons and animals dead of yellow fever, in their vomit, and even on the walls of yellow fever wards and in the earth of the cemetery, is named Cryptococcus xanthogenicus. Wherever it existed it served to inoculate animals, and a guinea-pig kept in a confined space containing a jar of fresh earth from the cemetery very soon died, while other guinea-pigs kept in a similar space with the same earth, sterilised by heat, remained sound. A series of animals could be inoculated from one another, and the virus appeared to lose nothing of its activity by transmission, so that Professor Freire had to try some other plan for attenuating it for "vaccination" purposes. This he succeeded in doing by means of gelatine cultures in Pasteur's flasks. After the seventh culture guinea-pigs inoculated with the attenuated virus appeared to suffer only a slight indisposition, instead of dying, as those inoculated with each of the preceding ones did. The writer and a number of other medical and lay persons, together with Dr. Freire himself, were inoculated or "vaccinated" with the seventh culture, and none of them experienced more inconvenience than slight headache and transient malaise. They were subsequently proved to be quite unaffected by much more virulent cultures. Dr. Issartier states that the yellow fever mortality among the protected persons in Rio was 1·6 per cent., while among the rest of the population it was 13·7 per cent.

BURIAL REFORM.

A MEETING of the Church of England Funeral and Mourning Reform Association was held in the Town Hall, Chester, on the 25th ult., the Dean presiding. In addition to the more immediate objects of the Association, the promotion of burial in perishable coffins and the use of simple "earth to earth" graves, several other matters of medical interest were discussed. Thus, one of the speakers, who, though not a member of the Church of England, sympathised heartily with the Association and its work, commented severely upon the risks to which the mourners and other attendants at funerals were exposed by standing bareheaded in inclement weather. This is no new grievance, but has been frequently discussed before and admits of a very easy remedy. Clergymen are not required to be bareheaded even while reading the service, but may, and often do, wear the college cap, or a velvet skull-cap. In Wales, Welsh wigs used to be provided for the purpose; and those who are frequently called upon to officiate at funerals, such as cemetery chaplains, almost invariably adopt some covering for the head. If, therefore, the officiating minister in the very act of his sacred office may remain covered, there can be no reason why laymen should stand bareheaded under any circumstances, much less in a broiling sun, pelting rain, or in the teeth of a cutting east wind. The clergy have set the example; let the laity follow. The former consider their health as of greater importance than the mere appearance of reverence which would be exhibited by uncovering the head; laymen might, with equal reason, conclude that their own health is of greater importance than any increased amount of reverence on the one hand, or respect to the deceased on the other. Another point of interest was the custom of washing the body soon after death, which Mr. E[illegible] of Liverpool, in a paper read by him, condemned as a most unnecessary and often dangerous custom. He argued that while performed by some relative, nurse, or friend, and prompted by an affectionate feeling to pay the last act of attention to the dead, there was some justification for the practice; but when strange women were hired for the purpose he condemned it as a repulsive proceeding. His remark that after the battle of life the poor body should not enter into a fight with death and nature, but should literally rest in the grave, met with the general approval of the meeting. Resolutions in favour of funeral and burial reform were carried unanimously, and it was stated by the Rev. F. Lawrence of Westow Vicarage, York, the indefatigable secretary of the Association, that the cause is making rapid progress in all parts of the country.

BRAIN LESIONS FOLLOWING INJURIES TO THE HEAD.

POPULAR thought attributes a great many diseases to the agency of falls on the head. Doubtless in many cases the fall and the disease are but accidentally related. But we believe that injuries to the head may be the potent agent in the causation of many cerebral lesions. The belief that traumatisms can cause blood extravasations with laceration of brain-substance is of course well founded, but the doctrine that inflammations and new growths may arise as the direct result of injury can at best be based only on greater or less probability. If the fall or blow does not rupture vessels and causes no obvious bruising of cerebral tissue, can it so disorder the molecular processes of nutrition as to lead to the formation of tumours? An interesting case of aphasia, with loss of "ear" for music, has been placed on record by Kast. A youth, aged fifteen, fell from a cart struck his head against the wheel. The accident was followed by loss of consciousness which lasted several hours, and on restoration to consciousness it was found that the right side of the body was paralysed, and that, though he seemed to comprehend what was said to him, he could not utter a word. The paralysis slowly disappeared. At the end of two months the aphasia had altered its characters. The boy was no longer unable to say some words, but he had completely lost the artistic use of his vocal cords, though prior to his accident he was a distinguished member of a choral society. Thus he sang falsely and out of tune, and could not correctly follow the lead of another singer. After the expiration of two years, however, he regained perfectly, so it is said, the artistic use of his voice, but still remains largely aphasic as to the employment of words for the construction of sentences.

THE CANAL BOATS ACTS.

THE report of the Inspector under the Canal Boats Acts forms part of the last annual report of the Local Government Board. Speaking generally, it would appear that there is distinct evidence that the legislation as to canal boats has been satisfactory, and that the local authorities are becoming more and more alive as to its necessity. The registration of boats seems to be fairly well carried out, but in point of sleeping accommodation and of the ventilation of the older boats improvement is still wanting. The water-supply for the occupants of barges is also a matter which calls for more attention, for although suitable receptacles are, as a rule, available for a proper water, yet the canal water often forms the only available supply, and it is rarely fit for drinking purposes. It is, however, satisfactory to learn that the indecent herding together of men, women, and children is now hardly ever met with, and that in consequence of the supervision exercised, many of the younger women who formerly followed a very questionable sort of life in wandering about with barges have now engaged themselves as domestic servants

or otherwise. As instances of the action being taken, we may refer to the following. In Manchester, where 592 boats have now been registered, 58 summonses were taken out, and in 37 cases fines were imposed or costs were enforced, together with a caution as to the future. In 13 of these cases the cabins were dirty, and in 6 they were overcrowded. In Wolverhampton 502 boats have been registered, and there were 126 cases in which offences against the Acts were detected. About a fourth of these were taken before the magistrates and fines inflicted, a large proportion being for breach of the regulation placing restrictions on the residence of girls over twelve years of age on board canal boats. At Bristol special provision has been made for removal to hospital of any cases of infectious diseases on the boats, but, speaking generally of the kingdom, few cases of such disease were met with afloat. During the past decennial period the death-rate amongst bargemen, lightermen, and watermen was nearly twice as high as amongst agricultural labourers; there is therefore ample room for improvement in this respect amongst the floating population of our canals and rivers.

THE EFFECT OF RETAINED MEMBRANES ON THE PUERPERAL STATE.

DR. FISCHER, of Professor Slavianski's clinic, writing in a recent number of the *Vrach*, gives the result of a number of observations made for the purpose of testing the commonly received view that portions of membrane retained in the uterus after the expulsion of the placenta are liable to produce serious consequences—as hæmorrhage and especially the so-called auto-infection or septicæmia,—and that therefore it is of the utmost importance that they should be removed by the hand or by intra-uterine injections. This view is supported by the authority of Winkel, Dohrn, Ahlfeld, and others; while Olshausen, Credé, Weiss, and Landau consider that there is little harm in the retention of even considerable portions of the chorion. Dr. Fischer's observations extended over 682 labours, in each of which he carefully examined the afterbirth. In forty-two of these cases (i.e., 6·2 per cent.) a portion of the chorion was retained. Credé's method of manipulating the fundus uteri gave the best results regarding the percentage of retention. In primiparæ retention was nearly twice as frequent as in multiparæ, the percentage being 9·1 and 4·9 respectively. Some effect appeared to be exerted by the time at which the rupture of the amnion took place, which, when either too early or too late, seemed to predispose to retention. Premature deliveries also were rather more frequently followed by retention than those at term. As a rule, the retained chorion came away in the course of from four to six days, generally in several small portions, sometimes, however, in fragments of considerable size, and in one case, where three-quarters of the chorion had been retained, it was passed entire on the fifth day without having caused either hæmorrhage or sepsis. Amongst the forty-two cases hæmorrhage occurred only four times, and was always easily arrested either by hot irrigation or by ergot and manipulation of the uterus. When, however, we learn that out of the forty-two cases manual extraction of the fœtus was required seven times, and that a considerable loss of blood occurred during the third stage eleven times, four cases of slight post-partum hæmorrhage does not appear at all excessive. With regard to pyrexia, in twenty cases, or 47·6 per cent., there was none; in twelve, or 28·6 per cent., the thermometer, which was always used thrice a day, once registered a rise above normal; and in ten, or 24·8 per cent., there was more or less pyrexia. In order to compare these with cases in general, Dr. Fischer gives the results of similar observations made on all the cases he has attended for the last two years. These show that there was no pyrexia in 58 per cent., that the temperature was only once above normal in 17·6 per cent., and that there was pyrexia in 24·4 per cent.; so that the ratio of appreciable pyrexia was about the same in the cases in which retention occurred as in ordinary cases. A slight amount of endometritis occurred in three out of the forty-two cases. Dr. Fischer concludes from his observations that there is no ground for supposing that retention of fragments of membrane gives rise to "auto-infection," and considers that the commonly received view is fraught with danger, inasmuch as it tempts the accoucheur, when sepsis occurs, to throw the blame, not on himself, as he ought to do, but on some fancied auto-infective process, and thus probably prevents his being as particular as he should be in employing antiseptic methods in the management of the labours he has to attend.

THE BOSTON COTTAGE HOSPITAL.

THE annual meeting of the subscribers to this institution was held on Thursday, October 8th, when the annual report was presented by the committee. It would appear that this hospital, which still retains the name of "Cottage" Hospital, had a small beginning some years ago, and was for some time conducted on the principles which are found in similar institutions. Here the original intention was simply to provide nursing and food, each patient being attended by his own medical attendant, who, we presume, supplied medicines and other necessaries. As the advantages of the hospital became known, the applications became more numerous, the necessity for a larger building was recognised, and the present institution built. At this time the subscribers paid for medicine and surgical instruments, in addition to their maintenance of the hospital, and patients were admitted from surrounding villages who could not conveniently be attended by their own medical men. Boston is a town containing several practitioners, each of whom would be entitled, under the old rules, to attend his patient; and it could hardly be conducive to the well-being of the inmates, or to the maintenance of the discipline of the establishment, to have a number of practitioners visiting, possibly at irregular hours, and sometimes several at a time. It was therefore thought advisable to limit the number of medical men and form a responsible staff of three, who in the opinion of the committee were best qualified to act for them to the advantage of the patients. Of late there has been, it would seem, an agitation raised with the view of increasing the number of the staff of the hospital, not because the present staff is either inefficient or too small—indeed the committee is quite satisfied with the present working of its staff and thankful for the services rendered by it,—but because it is alleged that some medical men in the town are anxious to continue attendance on such patients as have been under their care outside It seems to us that it is in the power of the subscribers on appeal to say whether it is their wish to increase the staff or not. If it is, then either all the practitioners who wish ought to be allowed to attend any of their patients who may be there, in conformity with the original intention of the founders, or after notification of the proposed increase the addition to the number should be made by a majority of the votes of the subscribers. It is a pity that some of the expressions used at the meeting have given offence; all the statements made tend to show that the committee is satisfied with the present arrangement, and it was agreed that no general meeting be called to alter the rules unless a requisition signed by one-fourth of the subscribers be received by the secretary. We much regret to see it stated that one cause of the diminution of the Hospital Sunday Fund for the benefit of the hospital was due to the agitation raised in the town. It might be well for the subscribers to consider whether the hospital retain the title of the Boston Cottage Hospital or be called the Boston Hospital only.

DR. DESNOS ON RUTHERFORD'S HEPATIC STIMULANTS.

Dr. DESNOS has communicated to the Académie de Médecine an account of a number of observations made in La Charité on the clinical effects of some of the hepatic stimulants recommended on physiological grounds by Prof. Rutherford. Specimens of baptisin, sanguinarin, juglandin, and phytolaccin were obtained from Edinburgh, and administered to forty-eight patients suffering from various chronic affections, or convalescent from acute diseases. They were not confined to bed, as the recumbent posture itself favours constipation. The quantities given in each case generally varied from 10 to 30 centig. in pills, one half being given an hour after breakfast, the other at 2 P.M. Sometimes a larger quantity was given, and then a third dose was ordered at night. No gastric disturbance was ever observed as a consequence of taking these drugs, and griping pains only occurred under exceptional circumstances. As a rule, evacuations were produced spontaneously sooner or later after taking the pills—occasionally, indeed, a few hours after the first dose, but sometimes an enema of plain water was required, though in these cases the character of the stool showed that the drug had produced a softening effect upon it. Dr. Desnos remarks that enemata are frequently required to complete the action of even very active purgative medicines. Sometimes a single stool was produced; sometimes several were passed on the day following the administration of the pills; and occasionally with patients who were habitually constipated the bowels acted regularly from the time the hepatic stimulants were taken. In some cases repetitions were required, and in some the drug seemed to lose its effect, and recourse was had to different remedies altogether. The bulk of the stools voided varied, being sometimes very considerable. Occasionally fatigue was complained of, but generally the patients felt much relieved. Very exceptionally no evacuations at all were obtained. Baptisin proved itself a reliable purgative and cholagogue in doses of from 10 to 30 centig.; it occasionally, however, caused griping. Sanguinarin, though given in quantities of 60 centig., failed entirely. Juglandin, in doses of from 10 to 20 centig., acted similarly to baptisin, but in two cases produced several dysenteric stools and griping. Phytolaccin, in doses of from 10 to 20 centig., seemed to act more certainly, and to have a greater tendency to regulate the bowels afterwards than any of the other substances, Dr. Desnos therefore prefers it to them, and considers that "it is capable of enriching the therapeutics of constipation with a valuable agent."

OFFICIAL VACCINATION RETURNS.

THE vaccination returns as to children whose births were registered in 1883 were completed during the course of last year, and they show that 85·6 per cent. were successfully vaccinated, whilst 9·2 per cent. died unvaccinated, 0·01 per cent. remained unvaccinated on account of their having had small-pox, 0·1 per cent. were certified as insusceptible of vaccination, in 0·9 per cent. vaccination had been temporarily postponed, and 4·2 per cent. remained wholly unaccounted for as regards vaccination. The percentage of default is slightly higher than any previously recorded; the increase having taken place in the eastern, the north-midland, the north-western, and the northern divisions of England and Wales. In the metropolis there has been a progressive and substantial improvement; thus in the five years 1873-77 the average percentage of births unaccounted for was 8·1, whereas in the period 1878-81 it had fallen to 6·8. In 1883 the unions of St. Pancras, Poplar, Fulham, Kensington, Whitechapel, and Woolwich stand in the foremost rank for efficiency. But in the provinces the amount of default has slightly risen, bringing about this result, Keighley with an amount of default reaching 68·3 per cent., Leicester with 43·8 per cent., Dewsbury with 20·0 per cent., Derby with 18·9 per cent., Barrow-on-Soar with 16·8 per cent., Oldham with 15·5 per cent., and Easington with 15·0 per cent., occupy the most prominent positions of unenviable notoriety. On the other hand, in Birmingham and Leeds the percentage of births unaccounted for is as low as 1½ per cent., in Bolton it is only 1·2 per cent, and in Huddersfield 1·0 per cent. The day of reckoning has yet to come, and unless there be an amendment, which we can hardly hope for until the lesson has been learnt by a bitter experience, the populations of the unprotected unions will some day have cause to envy those communities which, in this matter, have not blindly followed the guidance of fanatics, who, by the way, are almost invariably themselves vaccinated.

INTERESTING CASE OF RABIES AT BRADFORD.

WE understand that one of the Bradford police force was a fortnight ago severely bitten by a dog supposed to be mad. The evidence obtained from a post-mortem examination of the animal, made by Dr. Hime, was, as is usual, quite undecisive. However, Dr. Hime, to decide the question, applied Pasteur's test, by inoculation of a rabbit with material taken from the dog, he being the first to do so in this country. The rabbit has shown the usual symptoms of rabies, and there is no longer any doubt as to the dog having been rabid. It had bitten the man on two fingers of his right hand, and died ten days after while under Dr. Hime's observation. It is extremely fortunate that Dr. Hime, who for a considerable time was in Paris studying Pasteur's method, has been thus able to utilise his knowledge of the subject. He has previously been able, by application of the same method, to pronounce several suspected dogs to be free from rabies. Fortunately the policeman was, by Dr. Hime's advice, despatched to Paris for treatment, and his public history will be watched with interest. Dr. Hime, it will be remembered, took over to Pasteur a party of nine persons bitten by a rabid dog last March, and subsequently had himself to undergo a course of treatment by M. Pasteur for serious injuries received. One person bitten by the same dog which bit the nine died of rabies, but he was not treated by Pasteur.

INFECTIOUS DISEASE AND THE DUNDEE TAILORS.

THE Dundee branch of the Amalgamated Society of Tailors adopted at their last meeting the following resolution:—"That the thanks of the Dundee tailors be tendered to the editor of THE LANCET for voluntarily taking notice, in that most valuable paper, of the greatest curse that surrounds our trade, and the great danger and consequent heavy death-rate that is inflicted on the public, by so many of our master tailors." In communicating this resolution to us, the Secretary of the Society adds that the sum of 15*s.* a week given to tailors who are kept away from their workshops when suffering from infectious disease is not paid by the Dundee sanitary authorities, but by the Tailors' Trade Union. This is highly creditable to the men who out of their slender earnings contrive to save sufficient to provide such solid help in time of need. But we maintain that it is the community which owes them compensation. Isolation is not necessary for the cure of a fever patient; on the contrary, it may on certain occasions, retard a convalescence. During the period of desquamation the patient remains in-doors, when a short walk in the sun would be a pleasant restorative. But the inconvenience, the expense, and the loss of business resulting from isolation are rightly imposed to save the public at large from the danger of infection. Surely, then, it is the inhabitants generally that stand under obligation towards the individual who suffers on their account. A few

workers may be as provident as the Trades Unionists of Dundee, but this does not justify the community in shirking its responsibilities. What, also, is to happen to those who do not belong to a union or a benefit society? Practically the fear of sanitary and preventive measures compels the poor to conceal the presence of infectious disease. The work they do is consequently contaminated, and the community is thus punished for neglecting the obvious duty of paying a liberal compensation to those who sacrifice their personal interests to preserve the public health.

DIRECT REPRESENTATION: LIST OF CANDIDATES.

THE following gentlemen are the candidates for election as direct representatives for the respective divisions of the kingdom. We place them without favour in alphabetical order. We have no wish to be severe on any candidate who does not obviously represent over-represented bodies by history or by actual office. Five general practitioners in the Medical Council would be like letting fresh air into the Council room. If the general practitioners use their votes to elect officials of corporations, they will deal a deadly blow at the principle which has been conceded so tardily and scantily:—

England.

Balding, D. B., F.R.C.S. Eng., Royston.
Brown, George, M.R.C.S., London.
Bullock, H., F.R.C.S. Eng., Isleworth.
Carpenter, R. H. S., L.R.C.P. Lond., Stockwell.
Dolan, T. M., M.D. Durh., F.R.C.S. Edin., Halifax.
Foster, Sir B. W., M.D., F.R.C.P. Lond., Birmingham.
Glover, J. G., M.D. Edin., London.
James, Prosser, M.D. St. And., London.
Morris, Edwin, M.D. St. And., F.R.C.S. Eng., Spalding.
O'Connor, B., M.D. Qu. Univ. Irel., London.
Richardson, B. W., M.D. St. And., F.R.S., London.
Taaffe, R. P. B., M.D. Lond., Brighton.

THE BACILLI OF RHINOSCLEROMA.

AT a meeting of the Imperial Society of Physicians of Vienna on October 20th, Dr. Paltauf demonstrated preparations and cultures of the bacilli of rhinoscleroma, which he had made in conjunction with Dr. V. Eiselsberg (*Münch. Med. Woch.*, Oct. 26th). These bacilli discovered by v. Frisch are short thick rods, which were found by Cornil and Alvarez to possess a characteristic capsule. They are best demonstrated by staining the fluid expressed from the new growth with gentian-violet, or with an after stain with iodine and safranin, when they appear as oval cocci, or as short rods twice as long as broad, generally encapsuled. In sections they are well seen by staining first with gentian-violet and then rapidly immersing in clear oil. The capsules may be brought into view by staining with carbol-fuschin and washing in acetic acid, or by thymol-gentian-violet and acetic acid, or by aniline-water-safranin. These bacilli may be well cultivated in gelatine, agar, and potato. They form beautiful needle-like cultures similar to those of the pneumococcus—a similarity so great as to render them indistinguishable. Animals cannot be inoculated with the disease. In a mouse inoculation of the bacilli excited the formation of an abscess in which non-encapsuled bacilli were found. After inoculation into the pleura, animals die in from twenty-five to twenty-eight days, and in the exudation and swollen spleen numerous diplococci or short rods indistinguishable from pneumococci were found. After subcutaneous inoculations in fatal cases numerous encapsuled cocci were found in the blood, spleen, and at the site of inoculation. Animals surviving inoculation were susceptible to further inoculation. By a comparison with the pneumococcus, it was found that animals infected with the latter died in two days, those infected with the bacilli of rhinoscleroma died in five days or survived. Out of six guinea-pigs that were inoculated two died, one exhibiting an interstitial pneumonia with numerous bacilli, the other dying with acute pleurisy and pericarditis—associated with encapsuled cocci. Rabbits are insusceptible—another analogy of this microbe with Friedländer's pneumococcus,—so that the only difference established between the two kinds is that the one is less virulent than the other.

CONTAGIOUS DISEASES (ANIMALS) ACT, 1886.

THE Local Government Board have addressed a letter to local sanitary authorities pointing out the powers they possess under the Contagious Diseases (Animals) Act of 1886, and the Orders in Council made thereunder. These powers are mainly those of making and enforcing regulations for the cleanliness of cowsheds and the better keeping of cows, and for guarding milk against infection or contamination. Until the passing of this Act sanitary authorities had no other control over these places than is conferred by the general sanitary Acts over all premises situated in their district. Now it will be their own fault if every cowshed is not properly paved, drained, and cleansed, sufficiently lighted and ventilated, and supplied with wholesome water. Some difficulty, due to the habits and customs of farmers, will have to be surmounted before farm buildings are put into order, and perhaps this is not lessened by the fact that farming is not nowadays sufficiently profitable to leave money for extensive improvements and repairs. Nevertheless, if this duty is seriously undertaken by the administrators of the law, very much can be done. At trivial cost, and with very great advantage, all cesspools and other sunken receptacles for human excreta can be abolished; the use of pails renders them unnecessary, and relieves the farmer of a risk which is always attendant upon their presence on a farm. The better paving and draining of farmyards will do much to improve the conditions under which cows live, and money expended in these directions will make ample return in promoting the health of these animals. The necessity for better water-supply is obvious to all those who have experience of country farms, and it may be anticipated that the means which will be taken for preventing the pollution of the soil will have considerable influence upon the condition of neighbouring wells. It is matter for extreme regret that the Act is practically powerless to enable precautions to be enforced against infection or contamination of milk due to some ailment of the cow. Mr. Power's recent report on "milk scarlatina" has shown the necessity for legislation for this purpose; but although local authorities can make regulations prescribing precautions to be taken by purveyors of milk and persons selling milk by retail against infection or contamination, these words only relate to conditions which may occur after the milk has left the animal. The Milkshops Order of 1885 prohibits the use of milk for food whenever disease exists among the cattle in a dairy or other

building or place; but unfortunately the word disease is limited in its application to certain specified maladies, and ailments which we are beginning to learn have the most serious effect upon the health of milk consumers are not included in this restriction. It is, however, somewhat satisfactory that the authorities who are responsible for the condition of cowsheds and dairies are those whose duties primarily relate to the prevention of disease in man. Some steps must of necessity be taken to learn the causes of milk epidemics which are constantly destroying life in different parts of the country. The legal powers of these authorities are doubtless limited, but the moral duty remains, which we hope will be fully recognised, that every effort should be made to study the origin and prevent the occurrence of these calamities.

PNEUMOTOMY.

IT is possible that cavities in the lung may come to be regarded as amenable to the same kind of surgical treatment as is regularly practised for empyema. An interesting case of pneumotomy was read before the Académie de Médecine by MM. de Bearmann and Pengrueber. The patient was a child, aged twelve years, who had the physical signs of a large cavity situate in the middle of the right lung. The sputa were abundant and fetid, being expectorated five and six times a day by the aid of paroxysms of coughing. A large U-shaped incision was made at the level of the sixth rib, below the angle of the scapula. The periosteum was stripped off this rib, and some five centimetres of the rib resected. The thermo-cautery was next passed into the lung, so as to open the cavity, which was judged to be immediately adjacent to the region of the incision, and just above the level of the seventh rib. At the depth of about one inch the cavity was entered, and much fetid matter escaped. The incision was then enlarged, so that the finger could be passed freely into the cavity. A drainage-tube was inserted, and the wound sutured and dressed with iodoform. Very little blood was lost. The wound progressed satisfactorily, and had nearly healed at the end of three weeks.

THE SANITARY CONDITION OF RIPON.

AN important memorial has been presented by the medical practitioners of Ripon to the Sanitary Committee of the Town Council. It draws attention to the unsatisfactory condition of the drainage of the city, and it is alleged that were it not for this, for the deficient sewer ventilation, and for the surface nuisances, visitors would be induced to make much more lengthened stays in the place, and others would resort to it for the purposes of permanent residence. In the end it was resolved to invite the medical profession of the city to confer with the Sanitary Committee on the subject of their memorial. It was, perhaps, unfortunate that the report of the medical officer of health for the city should have been presented at the same meeting, and that in connexion with a death-rate of only 13·2 per 1000, and with a comparative absence of infectious deaths during a single quarter; the opinion should have been expressed that the report would doubtless dispel the excitement prevalent respecting the health of the city. We cannot think that Mr. Husband would wish to minimise the gravity of such disease-producing conditions merely because the natural result of allowing them to exist has not yet been actually brought about. The real point at issue is—are such conditions prevalent as the memorial refers to, and, if they are, what do the Corporation intend to do in order to prevent mischief arising from them? Unfortunately, we have a recently issued official report on Ripon before us, and the Local Government Board inspector, in describing the city, speaks of yards retaining [redacted] of houses huddled together without regard to the need for the circulation of air about them; of middens clustered about dwellings; of new houses built on "tips" of rubbish and ashes; of a water-supply derived from the Ure, which is higher up polluted with sewage, although active indications of pollution are not chemically discoverable in certain given samples; of very bad sewers and faulty house-drains; and of pollution of the Ure by the city sewage. These are the points to which the direction of the Town Council should be directed, and we may assume that their gravity will not be under-estimated because of comparatively small death-rates.

PROF. CHARCOT ON HYSTERICAL CONTRACTURE.

A CORRESPONDENT writes:—"The recognition of the fact that hysteria affects the male as well as the female sex is likely to have considerable influence on the practice of medicine, and the profession is deeply indebted to the labours of Professor Charcot and his assistants at the Salpétrière, who first called attention to this fact, and who are still working to elucidate the phenomena of this mysterious disease, so that with the progress of time we may hope for as complete a knowledge of this as of other diseases of the nervous system. One of the most recent discoveries in connexion with this subject is the fact that contractures are easily produced in persons suffering from hysteria by the application of various agents, of which bandages are the most important from the frequency of their application, and from the fact that the resulting contracture is usually supposed to be due to the original injury. The following account of a case which was used by Professor Charcot to illustrate his views in a lecture, subsequently published in the *Progrès Médical*, will serve to illustrate the importance of the recognition of the phenomena of hysteria. A butcher, thirty years of age, in whose antecedents nothing worthy of note was found, in the course of his work sustained an injury from a fall of a heavy mass of beef. At the time he did not lose consciousness, but felt stupefied, he heard a noise as of something breaking in his left arm, but felt no pain either at the moment or subsequently, but he found that all voluntary movement in his left arm was quite gone, and it gave him the idea as if the limb was absent. Two days after the accident he went to the Hôpital St. Antoine, when the hand, wrist, and fingers were considerably swollen; there was no voluntary movement, no rigidity, and no sensation. For fifteen days the arm was treated with poultices, and subsequently for forty-five days put up in a plaster-of-Paris bandage, at the end of which time the apparatus was taken off, but the arm was found to be in a state of contracture. Chloroform was administered, and the rigidity quite disappeared. There was no evidence of joint lesions or contractions of tendons such as might be expected to occur in a limb placed at rest for such a period of time. An apparatus was applied, with a view of straightening the fingers, but the flexion was so strong that it quickly became useless. After leaving St. Antoine, the patient visited several other hospitals, and was finally handed over to the care of Professor Charcot, at which time the forearm was in a state of supination, the fingers were flexed on the palm with a tendency to overlap each other, and the thumb was so strongly pressed on the index finger that it had made a considerable depression in the flesh. There was no voluntary movement, the reflexes at the wrist and elbow were exaggerated, and when called into action produced a trepidation of the muscles. There was slight atrophy of the limb, but no alteration in electric reaction of the muscles, and no evidence of joint or tendon lesion. There was a hemialgesia of the left side, with obnubilation of the senses of taste, hearing, and smell, and retraction of the field of vision of the same side. Sometimes in the arm there was a sensation of an aura, which mounted

to the throat, producing a sense of suffocation and sometimes aphonia lasting a day or two. Such is the case, and the interpretation is as follows. The original injury gave rise to monoplegia flaccida of the left arm in a subject showing most of the objective signs of hysteria, of which disease this kind of paralysis is often a symptom, but by the application of bandages this monoplegia flaccida was changed into a monoplegia spastica. In support of this interpretation the Professor exhibited another young man who had been suffering six months from a monoplegia flaccida of one upper extremity with anæsthesia, in whom one or two turns of an Esmarch's bandage produced a condition of contracture. This, however, lasted only as long as the bandage was applied, but, as pointed out, if applied for a long period of time, it is extremely probable that this transitory condition would become chronic. Another interesting fact is that in the first of the two cases the application of a bandage to the left lower extremity produced a contracture resembling a true talipes equinus.

GLASGOW UNIVERSITY CLUB, LONDON.

THE inaugural dinner of this Club took place in the Holborn Restaurant on Friday, October 22nd. The chair was taken by Prof. Sir Wm. Thomson, F.R.S., who came to London specially to preside at this the first social gathering of the Club. In proposing the toast of the evening, Sir W. Thomson dwelt upon the large measure of success which had attended the Club, its list of members already numbering over one hundred names, and its financial position being very prosperous. The other speakers were—Sir Joseph Lister, Bart., Prof. Gairdner, Prof. Hales, Surgeon-Major Muir, M.D.; Drs. Guinness, Mitchell-Wilson, Chalmers, Finlay, Heron, and Carfield; and Messrs. McClymont McIlraith, Turner, and Legge. Fifty members of the Club and guests sat down to dinner, and several gentlemen wrote expressing regret for their unavoidable absence. Songs and recitations were given during the evening by Drs. Guinness, Chalmers, Yarrow, and Fisher.

FOREIGN HOSPITALS.

MR. F. C. CARR-GOMM, Chairman of the House Committee of the London Hospital, has recently published notes of visits which he paid during the summer now ended to some of the general hospitals in foreign capitals, which are perhaps somewhat less known than those in Western Europe. The institutions visited by Mr. Carr-Gomm were the Commune Hospital at Copenhagen, the Marie Magdalene at St. Petersburg, the Foundling Hospital at Moscow, and the City Hospital at Stockholm. In the pamphlet before us, particulars are given of the building and fittings, staff, conditions of admission to, and dietary of these charities, from which it appears that the bedding supplied to each patient is superior to, and the diet certainly more varied, even if not better than, that used in this country. It must be remembered, however, that it is very hard, if not impossible, to make any comparison whatever between our administration here and that of foreign hospitals, because not one of the latter is supported by voluntary contributions, but all are either institutions directly under the national government or under their several municipalities. The principal noticeable results of the different system to ours are, first, that, with an equal determination to secure the greatest efficiency of administration, they are not hampered by an incessant striving after greater economy in every department; and, secondly, that the other hospitals in the city, being under the same management, are never perplexed with overcrowding, but can, as occasion requires, pass on their extra patients to other hospitals or take into their vacant beds the overflow of others. Each of these systems has, no doubt, its special merits and demerits, but it would be an evil day for us if it were ever found necessary to put our hospitals, like our Board schools and workhouses, on the rates, and to remove those incentives to private generosity which the existence of our voluntary hospitals so abundantly supplies, even though such a result might make the management of them infinitely easier.

UNIVERSITY OF LONDON.

ACCORDING to the present calendar (1886-87) of the University of London, "candidates who in or after 1885 have passed the Intermediate Examination in Science will be considered to have passed the Preliminary Scientific M.B. Examination." It having been pointed out to the Senate that this regulation as worded would inflict some hardship on students who had passed an equivalent, or even practically identical, examination in preceding years, it has been determined to allow to candidates who have passed on and after 1880 the same privileges as are accorded to those who only passed last year.

MALFORMATION OF THE ŒSOPHAGUS.

AN interesting and curious arrest of development and alteration in the anatomy of the œsophagus is described by M. Boisvert in the *Journal de Médecine de Bordeaux*, No. 13. The upper part of the œsophagus started from the pharynx in the customary manner, but was narrower than usual, and terminated in a cul-de-sac, somewhat dilated, behind the situation of the bifurcation of the trachea. The lower part of the gullet commenced at the bifurcation of the trachea as a tube, continuing the direction of the trachea, and after a short course of three centimetres terminated in the stomach. When milk was taken, it was received into the cul-de-sac and ejected therefrom partly into the trachea, whence it found its way into the second part of the œsophagus. It is needless to say that with each ingestion of food attacks of asphyxia from the first nearly took the life of the infant, but did not end fatally until nine days had elapsed. The epithelium which lined the two parts of the œsophagus was of the stratified variety.

MANGE IN FOXES.

A WIDE extension of mange in the fox is creating much concern among lovers of the popular and health-giving recreation of fox-hunting. As the fox approaches more and more to the domesticated habits of the dog, he becomes liable to the maladies and surfeits of an artificial life. It has been found impossible in some of the most fashionable hunting localities to breed and rear a sufficient number of foxes. They have often to be imported from districts where fox-hunting is impossible, and in some instances from the Continent. This necessitates for a time artificial feeding and confinement, which has to be continued even after the cubs are turned down, in order to retain them in the locality where there has been a dearth of them. The development of mange among the imported animals and its communication to others are the result of "spoon-feeding" of cubs, as it is popularly called, which not only engenders disease but lessens the courage and fitness of the animal for sport. Good hounds refuse to run an artificially reared fox; thus there is danger of bringing the sport by such artifice into disrepute. Another reason why home-bred foxes are fed artificially is that it lessens their destructiveness. Pheasants and poultry are safer where foxes are fed. But food with "fleck and feather" is the natural aliment of the fox, and if he is to be kept fit for the sport of fox-hunting, as it is understood by true sportsmen, this he must have, even to the detriment of the pheasant-preserve and the hen-roost. In our [illegible] of life it is important for

purposes of health to retain and encourage out-door recreation; but for the man of middle life it becomes more and more difficult to indulge in the physical recreation suited to his earlier years. Fox-hunting and shooting are exceptions to this, for they can be indulged in to the verge of old age. To many a hard-worked man in a profession or in business, it is the only recreation and relief to the cares of duty. It is therefore a matter of regret that anything should interfere with this health-giving recreation.

THE SEWERAGE OF BROADSTAIRS.

THIS watering-place, so attractive to many who wish to combine some quiet and rest with the breeze off the east coast of Kent, appears to be in a sore plight as to its recently constructed works of sewerage. The outfall sewer has been carried along the foreshore at the foot of the chalk cliffs, and, owing to statements as to its inefficient working, the surveyor was instructed to report on it. He found considerable deposit in it, especially in "that part which is 14 in. out of level." The concrete around the pipes is so bad that the sea has in places washed it away, with the result of breaking some of the pipes. There is no ventilation whatever in the whole length of the outfall, and when the sewage is penned up the smell from the street ventilators is very bad indeed. The tidal flap at the outfall is broken off, and the works generally are in a "very alarming condition." Here we have the very conditions which have enabled people to say that before they had sewers they were comparatively healthy, but after sewers were provided the causes of typhoid fever became rife. And it is not only those who are responsible for the execution of the works who are to blame, for the lack of ventilation shows that, unless the original plans were departed from, the scheme itself was in part faulty. The chairman of the Local Board of Health appears only to desire to get the best possible remedy, and hence he proposed to communicate to the Local Government Board the whole facts, but ultimately a previous and shorter report than the one detailing the mischief was agreed to be transmitted to the central authority.

BITTERS IN DIGESTION.

IF any doubt still survived as to the prejudicial action of bitters on the digestive process, Dr. Tschelzoff's recent experiments may be regarded as having given it the *coup de grâce*. He has shown that bitter substances produce effects more hurtful than beneficial on digestion and assimilation, though till quite recently it was an article of popular, if not of professional, belief that these substances, while proving indifferent in the peptonification of albumen, yet hindered fermentation, and were therefore useful in certain ailments of the stomach. Experimenting with a great number of bitter substances, chiefly extracts, as being in more general consumption, he dealt with artificial digestion prepared with gastric juice; and in other cases he administered flesh to dogs, to some of which he gave bitter extracts, and, having sacrificed the animals, he weighed the quantity of the meat digested. In still other cases he kept the dogs alive while introducing into their stomachs, through permanent fistulæ, either flesh only, or flesh in union with bitters. He found invariably that in artificial digestion a small amount of bitter extract suffices to retard the digestion of fresh fibrine, and that the same effect, rather less pronounced, is produced in the natural stomach. Turning next to determine in what way bitters can whet the appetite, whether by augmenting the gastric secretion or by irritation of the mucous membrane, he experimented on dogs in whose stomachs he had made permanent fistulæ. After having introduced flesh only or flesh in union with bitters, he collected the gastric juice, and found that, in these cases, the bitter extracts diminished the gastric secretion, which underwent only a slight and brief augmentation when the bitters were employed in small doses. In every case the energy of the gastric juice was enfeebled. As a further result of experiment, he ascertained that bitters retarded the pancreatic digestion, while the biliary secretion was enhanced by extracts of absinthe and trefoil. The traditional belief, or rather assumption, that bitter extracts retard fermentation, is further shown by Tschelzoff to be fallacious. Indeed, the stronger the dose of bitters, the greater the intensity of the fermentation; in this case, however, the bitters do not behave in the same manner, and so the extracts of quassia and absinthe do not ferment, while fermentation becomes stronger in presence of powdered rhubarb or quinine. Finally, the putrefaction of organic substances, like blood or urine, he found to be favoured by the presence of bitter extracts, which in the organism also impede the assimilation of nitrogenised compounds.

PROFESSOR VIRCHOW AT THE BROWN INSTITUTION.

THE veteran pathologist of Berlin during his recent visit to this country spent an afternoon in inspecting the pathological work of the Brown Institution. The Professor-Superintendent, Mr. Victor Horsley, was able to show Professor Virchow many fair specimens of the kind of work that experimental pathology is pursuing in the face of much difficulty and many disadvantages in this country. Professor Virchow was shown the methods adopted in the pursuit of the pathology of myxœdema by Mr. Horsley. The centres of phonation in the cerebral cortex of the monkey, and those of the hand and thumb, as ascertained by Mr. Horsley, Dr. Felix Semon, and Dr. Beevor, were also demonstrated. Dr. Wooldridge explained his experiments on the blood plasma, and Messrs. Ballance and Edmunds exhibited specimens of their investigations on the ligature of large arteries in animals.

LOCALISED ELASTIC SPONGE PRESSURE.

PROFESSOR C. WEIL has for some time past been making use of pressure by sponges in several different classes of cases in which continuous and evenly distributed pressure seemed to be indicated. He now gives the results of his experience of this method in some articles in the *Prager Medicinische Wochenschrift*. The plan seems to have been first proposed by the late C. von Heine, and was mentioned by Professor Weil as long ago as 1877 at a meeting of the Prague German Medical Society. The plan adopted is to envelop the whole part in a firm plaster-of-Paris or soluble silicate bandage, and when this has set to cut a "window" in it exactly corresponding to the area over which pressure is required. Wedge-shaped pieces of sponge are then packed into the "window." This sponge pad is kept exerting constant pressure by the application of a strongly stretched indiarubber band encircling the whole part over the plaster-of-Paris bandage. The sponge should be of a fine quality, with small pores. It must also be quite clean and free from sand, but this must be effected by beating, and not by washing, which causes a loss of elasticity. Professor Weil knows of no other means of producing such rapid resorptive effects as sponge pressure, and he cautions his readers that if not carefully watched the articular synovial membrane and ligaments may become seriously impaired by the strong and constant pressure exerted on a joint. As a rule, the application must be removed and renewed every twenty-four hours, even when the patient is free from pain—as, in fact, is usually the case. After the first twenty-four hours an extensive exudation is found to have greatly diminished, the skin being blanched, wrinkled, and dried up, with here and

there little yellowish bullæ, showing the situation of the pores of the sponge. Sponge pressure was successfully employed in hydrarthrosis of the knee. Here the plaster-of-Paris bandage was applied to the thigh and leg, fixing of course the joint; the bandage, too, was carefully strengthened on the posterior aspect. The next day a "window" was cut out, so as to expose the anterior and lateral aspects of the joint. Three thick wedge-shaped pieces of sponge were then applied, a large one over the upper portion of the joint, and two smaller ones at the sides of the patella, the patella and its ligament being free. The sponges were kept *in situ* by an assistant, while the interstices were filled up with cotton-wool, and an indiarubber bandage tightly applied over all. This was allowed to remain for twenty-four hours. No pain was felt, nor was there any swelling of the foot, or blueness or numbness of the toes. When the bandage was removed the swelling was seen to be greatly reduced. The bandage was reapplied with new sponges, but not so tightly as before. In two days' time the swelling was no longer perceptible; after this, light pressure was continued for a few days. The plaster bandage was then removed and the slight return of the effusion produced by movement of the joint controlled by massage. The sponge pressure proved useful in many other affections of the joints, bones, and tendon-sheaths, also in angiomata and herniæ. Professor Weil proceeds to give some interesting particulars of a case of rheumatoid arthritis, another of a very large angioma of the infra-axillary region, and some of very large herniæ, in all of which sponge-pressure proved very useful.

ABERDEEN CHAIR OF MATERIA MEDICA.

OUR Edinburgh correspondent writes:—In consequence of the untimely death of Professor Dyce Davidson, of Aberdeen, a vacancy has occurred in the teaching staff of that university. There is a strong feeling in Edinburgh in favour of Dr. Stockman as a candidate for the post. Dr. Stockman is assistant to Prof. T. R. Fraser, in the Materia Medica department of the university; during the period of his teaching and laboratorial research he has earned the reputation of an able lecturer and a skilful investigator in experimental pharmacology, and during the present year has gained the high distinction of a university gold medal for his researches upon the action of vegetable astringents.

PROPORTIONAL MORTALITY.

AT the recent meeting of the British Association at Birmingham, Mr. Baldwin Latham, the well-known civil engineer, read a paper, of which the title was "Proportional Mortality," and its object to describe a method by which, in the author's words, the proportional death-rate of a district may be very correctly arrived at with great facility by the use of "constant" numbers. This method proposes to construct from the proportion of births to deaths registered in a population in a given year, with the help of the mean proportion which such facts for the same population bore to each other in the preceding census years, a figure which is somewhat arbitrarily called the proportional death-rate of the population. It is asserted by Mr. Latham that this so-called proportional death-rate would be a more trustworthy indication of the true sanitary condition of any district than the death-rate calculated for intercensal years upon the estimated population of the district. It may be fully conceded that, so long as our census enumerations are not held more frequently than once in ten years, estimates of population in the several years of these decennial periods, even if revised from time to time in accordance with the fluctuations in the recorded increase of inhabited houses on the rate-books, must necessarily constitute an element of uncertainty in the construction of death-rates. The value of Mr. Latham's proposed method mainly depends upon whether its results are more trustworthy than those supplied by what has been called the national system. Now, Mr. Latham's method assumes not only constant relations between the births and deaths recorded in a population, but attributes all the recorded fluctuations in those relations to the rise or fall of the death-rate; it practically assumes a stationary birth-rate. In the face, however, of the marked depression in the marriage- and birth-rates in England and Wales in recent years, the hypothesis of a stationary birth-rate must involve a fallacy. It is patent that a decrease in the excess of births over deaths may be due either to a decrease of the births or to an increase of the deaths, and that any system that attributes fluctuations in the excess of births over deaths solely to increase or decrease of deaths cannot yield trustworthy results. It may be true that the populations of towns are liable to more violent fluctuations than are their birth-rates, but it should also be remembered that it is far easier to test the approximate accuracy of an estimate of population than the accuracy of the hypothesis of a stationary birth-rate. It would, especially at the present time, be essentially unsound to adopt the hypothesis of a stationary birth-rate as a basis for the calculation of a death-rate. It should, moreover, be borne in mind that by far the most serious objections to the crude death-rate—that is, to the mere proportion of deaths to population—as a test of sanitary condition, are that this figure takes no account of the disturbing influences of varying sex and age distribution in different populations. It is scarcely necessary to point out that Mr. Latham's method makes no pretence of eliminating these disturbing influences, and cannot even on this ground claim any superiority over the national system.

MELBOURNE HOSPITAL.

AT an inquest recently held on the bodies of three patients who had died in the Melbourne Hospital from blood-poisoning, the jury stated that, from the mass of evidence brought before them, they were unanimously of opinion that the hospital is in a thoroughly insanitary state, is a constant menace and injury to sick poor, and calls for the immediate attention of the authorities with a view to its removal and rebuilding in a more suitable place. They also urged the Government, the committee, and the public to take immediate action, as they considered the hospital to be a disgrace to the city. The coroner, in summing up, described the out-patients' ward as a bureau and exchange for diseases. The insanitary condition of the institution has been previously recorded and commented on in our columns; but surely after such a vigorous and sweeping condemnation as this, the responsible authorities will feel it their duty to take remedial action at once.

THE FULHAM TRAGEDY.

THE last incident in this sad drama occurred on Thursday, the 28th ult., at the inquest on the bodies of Mrs. Leader and her infant child, which were recovered from the Thames three days previously. The further evidence of mental derangement, as sworn to by the husband of the deceased, is now valueless; but should it have transpired that the unfortunate woman had survived, it would then have been of paramount importance. The symptoms mentioned by Mr. Leader were pains in the head and side of the deceased after her confinements, excitability, and threatened violence to herself on some occasion previously to marriage. These deserve enumeration as being applicable to some future case of homicide in which the murderer may possibly not make away with himself. The jury, after a

short consultation, returned a verdict of "Found drowned," very properly making no allusion to the mental condition of the deceased mother at the time of the commission of the act.

SOCIETY FOR THE PREVENTION OF HYDROPHOBIA.

IT can only be regretted that there should be a *raison d'être* for such a Society. The Government of the land, instructed by its scientific advisers, ought to have prevented any occasion for its existence. To an unbiased mind it is difficult to understand why there seem to be insuperable objections on the part of some individuals to the eradication of rabies. The principal veterinary surgeon of the army, Mr. Fleming, has added the weight of his authority by supporting the new association. Dr. Burdon Sanderson and Mr. Victor Horsley are also amongst its adherents. But the Society has not only the support of the veterinary and medical professions; its position has lately been strengthened by a decision of the highest legal authority of the land. The Lord Chief Justice and his brethren have now spoken decisively on the meaning of the words "under proper control" occurring in the Dog Act of 1871. A dog must be either muzzled or led. The magistrates of London have now no excuse. The matter is settled. They cannot plead ignorance of the meaning of the Act. But the mischievous doctrine that moral control is sufficient has a deeper root in the country. A contemporary insists that we have already given the system of muzzling a fair trial, and then recommends that the police order be rescinded as useless, and even promotive of the spread of rabies. An argument of this sort is not worth notice. The order of the police has never been in proper force. We sincerely hope that the time will not be far distant when the enforced muzzling of every dog in the kingdom for the space of at least six months will give science the opportunity of testing its hypothesis, which is simply this: that rabies being a disease only developed as the result of contagium, the removal of those means by which the contagium spreads must infallibly lead to the extermination of the disease.

THE CHOLERA AT MALAGA.

RUMOURS are current that Asiatic cholera has broken out again at Malaga, Almeria, and other towns in Spain. Some persons have taken flight already, and the local authorities at Grenada have demanded permission to protect themselves by inflicting quarantine on all new comers. It will, we fear, be difficult to obtain authentic information, particularly with regard to the condition of affairs at Malaga. Last year, when the presence of cholera was freely acknowledged in many towns of Spain, the authorities strenuously maintained that Malaga was free from infection. It was admitted, it is true, that there were about 400 cases and 200 deaths from "gastro-enteritis of a choleriform description"; but the shipping interests of Malaga rendered it imperative to deny the presence of cholera at so important a maritime station. Nevertheless the cholera had broken out, though it never spread to the same alarming extent as in other great centres. Malaga, fortunately, possesses an excellent water supply. The Torremolinos stream, captured at its source, is brought to Malaga in iron pipes, so that it cannot be contaminated on the road. On the other hand, there are some inhabitants who persist in drinking the water from the old wells which still exist in several houses. These private wells and the defective condition of the town sewers and drains are quite sufficient to account for a recurrence of cholera. While these evils continue, it is futile to throw the responsibility on Italian or other vessels visiting the port. The climate of Malaga is one of the best in Europe for the treatment of several complaints. The town should be a fashionable and prosperous health-resort, as well as an important commercial port. The indolence and the ignorance of the Spanish authorities alone prevent the full development of these natural advantages. Let us trust that this double chastisement—these two years of cholera—may teach the indispensable lesson, and that the authorities, shaken by public opinion, will awake from their lethargy. Private wells could and should be closed at once. At small expense house drainage can be considerably improved. This much, at least, could be done immediately; while, in time, the means might be found to rebuild the sewers and provide efficient means of flushing. The large influx of visitors, seeking renewed health under the beautiful sky where the sugar-cane and the banana ripen in the open air would materially help to cover the cost of such sanitary improvements. The inhabitants of Malaga would thus increase their own prosperity, protect themselves against epidemics, and, by converting their town into a health-resort, help to save or prolong the lives of many thousand foreigners.

DR. MORTON'S CANDIDATURE.

DR. MORTON has been addressing a meeting of registered practitioners, and trying to convince them that, though he is actually the president of a corporation in Scotland, he is quite eligible to represent the practitioners of Scotland. We admit the courtesy and the ingenuity of Dr. Morton's address, but it is quite ineffective. A man cannot serve two masters, and Dr. Morton's primary duty as the chief officer of the Faculty is to serve it first. For the time being he has special obligations to a corporation already over-represented. There should be no doubt as to his rejection by the practitioners of Scotland. We are somewhat doubtful about the practice of "stumping." If medical men are to speak in all the chief towns as a condition of election, there will be a great temptation to talk nonsense, which Dr. Morton fortunately avoided, and the most eligible men will decline the ordeal.

INFLUENCE OF LIGHT ON FERMENTS.

IT would seem to be necessary to keep away from the light all ferments that are meant to act in the darkness of the stomach and duodenum. Mr. Arthur Downes has made observations on the influence of light on various ferments now frequently prescribed in cases of digestive disorder. Active solutions of malt diastase, pancreatic diastase, and trypsin were all rendered inactive by an exposure to sunlight in half-filled flasks for the space of one month. A solution of pepsine also became inactive after a similar amount of exposure. Even rennet had some of its properties enfeebled. Other flasks (control experiments) were kept in precisely the same conditions, with the exception that they were not exposed to light. The ferments in the vessels kept in the dark remained perfectly active.

SEWAGE DISPOSAL: ANOTHER SUGGESTION.

A CORRESPONDENT of the *Pall Mall Gazette*, who signs himself an "Architect," has suggested that the sewage of London should be strained through wire buckets, and the solids thus caught, cremated, the remaining liquid being subsequently disinfected. This proposal has brought down upon his head a storm of ridicule; engineers have freely pointed out the fact that by this method he would practically catch nothing, unless it were some of the babies, corks, indiarubber balls, dolls, clothes-pegs, &c., which find their way into the sewers, and that it would be necessary for the meshes of his wire net to be 5000 to the square inch if he is to meet with any success in extracting the finer particles

which constitute the bulk of sewage. The notion of thus dealing with an amount of sewage which, it is stated, would daily fill a box 40 ft. wide, 40 ft. high, and three miles long, has created much amusement in the minds of engineers, and it has been suggested that the "scheme is only a grave irony, not to be taken seriously, but in ridicule of the Metropolitan Board's tinkering with the problem." Is this possible? We note that the Metropolitan Board of Works are about to appoint an architect; recent action of this Board suggests the possibility that the correspondent may be a candidate for this office, and that he hopes to commend himself to their good sense by a proposal which is at any rate suggestive of the course they have adopted.

"THE UNIVERSITY COLLEGE (LONDON) GAZETTE."

THIS *Gazette* is published by the University College Society, an association formed and maintained with the object of promoting fellowship amongst the past and present students of University College, London. Professor Henry Morley initiated the movement, which resulted in the amalgamation of the various Societies that have their habitation within the walls of the Gower-street University. The *Gazette* is edited by a gentleman of excellent literary tastes, who dates his introductory letter from the Church of St. Mary Ottery, wherein was interred 500 years ago the mortal remains of John Gower, after whose name we have the street so famous in the annals of unsectarian movements. The *Gazette* will undoubtedly serve as an emblem as well as a promoter of the object the Society has in view.

THE BOWMAN LECTURE.

PROFESSOR ZEHENDER of Rostock will, as we have already stated, deliver the Bowman Lecture before the Ophthalmological Society on the evening of Friday, Nov. 12th, at 9 P.M. His subject will be "The Parasitic Diseases of the Eye." It is to be hoped that members of the profession will attend the lecture, and show by their presence their approval of the enterprise of the Society.

THE MYOPATHIC FACE.

AT a recent meeting of the Société Médicale des Hôpitaux, M. Landouzy exhibited three cases of progressive muscular atrophy affecting the face, shoulder, and arm. There is a family likeness in the different cases, owing to the existence in all three of the "myopathic face." This peculiarity of the countenance is best seen when an attempt is made to get signs of animation in the face. It is found that the patients cannot whistle, blow, extinguish a candle, make grimaces, or kiss, owing to the atrophy of the orbicular muscle of the mouth. A good description and phototype illustrations of this affection may be seen in Dr. Gowers' manual. This form of myopathy appears to be less rare than has generally been supposed, for Landouzy has himself met with nine cases in the course of five years.

SCARLET FEVER IN THE HUDDERSFIELD UNION.

A few weeks ago we reported an epidemic of scarlet fever in the Cumberworth district of this Union. We are now informed that the fever still rages, that fresh cases are occurring daily, and, although this state of things has continued for several months, we understand that no measures have been taken either for the closing or disinfecting of the various schools throughout the district. The disease has also spread into the adjoining Unions of Wakefield and Penistone. A few cases of typhoid have also been reported. We should like to ask, What are the authorities doing?

PROFESSOR VON ARLT.

WE regret to learn that since the amputation of the thigh which Professor von Arlt has undergone in consequence of gangrene, the vascular affection has made still further progress, and there is now little hope of the recovery of the great Vienna ophthalmologist.

FOREIGN UNIVERSITY INTELLIGENCE.

Buda Pesth.—A Professorship of Odontology is about to be established.

Leipsig.—Professor Ludwig will celebrate his seventieth birthday in December.

Santiago.—The Chilian government are about to appoint a Professorship of Physiology, with a salary of 15,000 francs and free passage.

THE Société Française d'Hygiène proposes for competition the following subject for the year 1887:—On Seditariness in Schools (Primary and Secondary), and on Intellectual Overpressure in Superior and Special Instruction. The first part will set forth the facts and observations which establish the evil; the second part will indicate the best means for combating it. The work should not exceed thirty-six pages of an 18mo pamphlet. The prizes offered are a gold medal of the value of 500 fr. (£20), and two silver medals of the value of 150 fr. each. The memoirs (written in French, English, German, Spanish, and Italian) should be forwarded in the usual academical form to the Secretary of the Society, 30, Rue du Dragon, Paris, before April 1st, 1887.

THIS year we notice throughout the country an accession of medical men as municipal representatives. Mr. W. Berry, J.P., M.R.C.S.E., after a contest, retains his seat in the Wigan Town Council; Dr. Braidwood of Birkenhead, and Dr. Moore of Southport, have both been successful; whilst Dr. Cross of Liverpool, and Dr. Bark and Dr. Wills of Bootle, head the poll in their respective wards. Dr. Cocker is mentioned as the jubilee mayor for Blackpool.

FOR some months past an epidemic has been reigning in the Greek seaside town, Nauplia, called by the local physicians ἕκτερος τύφου. It attacks especially the well-to-do classes, and generally proves fatal in three or four days. The bodies are of a yellow colour, and quickly become black. The Athens Sanitary Council describes the disease as pernicious yellow fever, and considers it of a non-infectious character.

THE annual public meeting of the Medical Society of University College, London, will take place on Wednesday next, Nov. 10th at 7 P.M., when the Fullerian Professor of Physiology in the Royal Institution of Great Britain, Professor Arthur Gamgee, F.R.S., will deliver an address on "Medical Education and Medical Degrees in relation to the present position of English Medicine."

IN the Saxon town of Colditz, which contains about 5000 inhabitants, and is situated near Leipsig, a society for leaving nature to cure diseases (Naturheilverein) is in course of formation. The six local practitioners have agreed to inform the members that they must not expect medical assistance from them in case they should change their minds.

A CASE of poisoning by the roe of herrings is reported in *La France Médicale* No. 122, by M. Belin. The chief symptoms were vomiting and diarrhœa, attended with severe colic and burning sensations throughout the whole course of the stomach and

THE first meeting of the Epidemiological Society will be held on Wednesday, Nov. 10th, at 8 P.M. The President, Dr. Walter Dickson, will deliver an inaugural address, entitled "A Review of the past year, with some Reminiscences of Cholera and Tropical Fevers."

THE Lord Advocate of Scotland has intimated, in reply to a correspondent, that he does not consider he can interfere in the matter of the purification of the Clyde, and is of opinion that the initiative should be taken by the Corporation of Glasgow.

THE Russian military medical authorities have decided to select an army surgeon annually, to be sent for two years to the asylum in connexion with the St. Petersburg Military Medical Academy for the purpose of studying mental diseases.

THE Society of Hygiène of France have conferred on Dr. B. W. Richardson, F.R.S., the distinction of Honorary Membership, in recognition of his many and original advances in sanitary science, and his labours for the public health.

THE next meeting of the Neurological Society will be held at Bethlem Hospital, S.E. on Wednesday, Nov. 17th, at 8.30 P.M. The subject for discussion, introduced by Dr. Savage, will be "On the Relationships of Epilepsy and Insanity."

DR. FAUVEL, the laryngologist, has just received the Cross of Officer of the Saviour from the King of Greece, for services rendered to the Greek surgeons who came to Paris to study his treatment of throat disease.

A SERIOUS outbreak of diphtheria is reported to have occurred at Hawkshead, a small town in North Lancashire, near Windermere. The local authorities have closed the schools for a month.

IN reference to a recent charge, we may say that the name of Donald McGregor Macguire, of Davies-street, Berkeley-square, does not appear in the Medical Register.

Pharmacology and Therapeutics.

GEDDES' FLUID EXTRACT OF HEMLOCK BARK.

THE Abies Canadensis, Canada Pitch, or Hemlock Pitch, is a tree which belongs to the natural order Coniferæ, and grows abundantly in the United States. The bark contains an astringent principle, and is used in some parts of America in the process of tanning. The fluid extract prepared from the bark is of value in the treatment of leucorrhœa and allied conditions. It is also recommended in inflammatory diseases of the mucous membrane lining the cervix, and in granular degeneration of the vaginal portion of the cervix itself. Geddes' Fluid Extract of Hemlock Bark is a reddish-brown fluid almost of the consistence of treacle, and having a very marked astringent taste. It is free from alcohol, and it is said that it will keep good for years in any climate. It would obviously be unfair to offer any opinion as to its therapeutic value without an extensive trial in a variety of cases.

VIBURNUM PRUNIFOLIUM IN THREATENED ABORTION.

The black haw, or Viburnum prunifolium, has long been used as a household medicine for various purposes, and was recommended some twenty years ago by Phares in cases of habitual or threatened abortion. Recently Dr. I. M. L'voff has made several trials with this drug, and, as the result of the success obtained by its means, recommends it as strongly as Phares. The number of cases in which he gave it was fifteen. Nine of these were cases in which abortion had become a habit; but by means of this treatment they all completed their full term of pregnancy. In the other cases signs of commencing or threatening abortion had already presented themselves—considerable hæmorrhage, shortening of the cervix uteri, and dilation of the os, together with slight griping pains in the uterus. In these the viburnum proved equally successful, the threatened abortion being arrested and the pregnancies lasting their proper time. The preparation usually employed was the dry extract, of which two grains were given four times a day in pill or powder. No disagreeable symptoms were ever produced by it. When the uterine pains were severe, a quarter of a grain of opium was added; but when this was not the case, the viburnum was given alone. The uniformly satisfactory results were obtained in spite of the fact that some of the women were poor, and, so far from being able to lie in bed, were actually obliged to attend to their household duties, so that the arrest of hæmorrhage and of the threatened abortion could only be ascribed to the viburnum administered.

SOLANINE.

An account of the properties of solanine has recently appeared in the *Bulletin Général de Thérapeutique* from the pen of Dr. A. G. de Montguyon. Solanine poisons the terminal motor plates of organic life, narcotises the medulla, spinal cord, and nerve trunks, and so produces paralysis of the terminal extremities of the sensory and motor nerves. These physiological effects allow solanine to be classed as an analgesic agent. Solanine may be prescribed without risk in strong doses. It has none of the inconveniences of morphine or atropine, has no cumulative action, and is specially a substitute for morphine. It does not cause congestion of the brain, even in elderly people, and probably not in children. In all conditions of excitement, spasm, or pain, solanine may be employed with a prospect of success. The ordinary dose is thirty centigrammes three or four times a day. It may be given fasting or after meals, and the dose may be greatly increased. For hypodermic injections a solution of the chlorhydrate in distilled water may be used in the proportion of from one to five centigrammes per dose, administered from two to four times a day.

CALOMEL IN HEART DISEASES.

According to several communications which have recently appeared in the Pesth and Vienna medical journals, calomel in doses of about three grains per diem has been observed to increase very largely the quantity of urine passed in cases of cardiac dropsy, thus determining in a very short time the existence of œdema due to heart disease. The mode in which it acts seems to be by promoting the absorption of the exudation, not by any direct effect upon the heart or kidneys; the strength, frequency, and rhythm of the pulse not being usually modified at all. Calomel is quite useless in nephritic dropsies, or those caused by obstruction of the portal system or by inflammatory processes. If diarrhœa occurs opium may be given, and if stomatitis, chlorate of potassium, without interfering with the absorptive action.

LANOLINE.

Lanoline, or rather "suint," according to M. Rohart, has a great affinity for sulphur (*British and Colonial Druggist*). It can absorb 110 times its own bulk of sulphuretted hydrogen. This sulphurised "suint" saponifies with great facility, even in the cold. Considering the penetrative properties of lanoline and the value of sulphur in many cutaneous affections, these facts are of some medical interest. It is already asserted that cases of sycosis that have proved refractory to other remedies have been greatly benefited by the sulphurised lanoline.

METHYLAL.

Methylal is believed by Signor Personali to possess anæsthetic and hypnotic properties. It is a mobile colourless liquid. Suspension of reflex action with deep unconsciousness, preceded by anæsthesia, were observed after subcutaneous injections in dogs. The effects in rabbits were less marked; the heart-beats were somewhat increased in number, the blood-pressure slightly lowered, and the respiration was slowed and rendered more profound. It is believed also to antagonise the spasmodic actions of strychnia. It relieves abdominal pain in human beings, and as an oint-

ment or liniment causes anæsthetic effects on the skin. As a liniment, the proportion is 5 per cent. of methylal in 85 per cent. of oil of almonds; as a syrup for internal administration, 1½ in 100 parts of simple syrup.

IODOFORM VASELINE IN SMALL-POX.

Dr. Colleville recommends in the *Union Médicale du Nord-Est* a vaseline ointment of iodoform, of the strength of 1 to 20, as not only an antiseptic emollient gratifying to the patient, but as somewhat anæsthetic, and as preventive of the formation of foul-smelling scabs and of pitting. Dr. Colleville has observed that in a case of confluent small-pox where iodoform ointment was frequently applied the vesicles were prevented from developing into pustules. No signs of iodoform poisoning have been observed in any of the ten cases in which this treatment has been employed.

NEW ANTIPYRETIC.

It is asserted that the leaves of a Ceylon plant, the Micbelia niligerica, have been found to possess marked antipyretic properties, a decoction of the plant acting in this respect more powerfully than cinchona. A peculiarly bitter principle is also said to have been extracted from the leaves.

THE COLONIAL AND INDIAN EXHIBITION.

[SECOND NOTICE.]

WHEN the Exhibition was first opened, the catalogues relating to the various colonies were not published, and the general catalogue was deficient in special information. Now, however, the catalogues of the different colonies would constitute a formidable and, in the main, an interesting library. These volumes are not mere dry enumerations of the objects exhibited, but generally contain essays on the colony and its principal resources. In some there are numerous illustrations, so that from every point of view information is forthcoming. The natural wealth of each colony is carefully shown, and though the data are given principally for commercial and manufacturing purposes, the facts are also most useful to the scientist. The botanist will find at the Exhibition many opportunities of extending his practical experience and of examining innumerable specimens. The chemist may see a variety of extracts from the plants special to each colony. New South Wales, for instance, has no less than four volumes ready for distribution to those who are seriously studying the condition of the colony. There is the official catalogue, a well-printed book of 478 pages. A report issued this year, under the authority of the Government of the colony, gives a detailed account of the progress, present condition, resources, and statistics of New South Wales; this occupies 221 pages. Then we have the Year-book of the colony, another 168 pages of very small type with illustrations; and a second and shorter work on the "Progress of the Colony," specially prepared by the Commissioners at the Exhibition. This enumeration will give some idea of the literature forthcoming, and the other colonies have shown similar energy in this respect. From these books we gather that the mean annual temperature at Sydney is 62·7° Fahr., that the average birth-rate was 37·90 per 1000 in 1884, the death-rate only 15·88, and marriages 8·35. Mortality tables ranging over periods of ten years are missing, and the above figures therefore cannot be taken as conclusive. In some cases facts are forthcoming demonstrating the energy of colonists with respect to public enterprise bearing on the preservation of health. Thus, the Sydney waterworks will cost more than £2,000,000 sterling; it is necessary to cut through nearly five miles of solid rock. £500,000 sterling is now also voted by the Government to supply several smaller towns with water. Side by side with these great public works, there are, of course, details and exhibits relating to individual firms and private enterprise; and among these we noted a case of candles and night-lights in the court devoted to New South Wales, which are manufactured with the oil of eucalyptus; by the burning of these lights peroxide of hydrogen is thrown off, and this should not merely act as a disinfectant, but relieve complaints of the respiratory organs, especially spasmodic asthma and bronchitis. We have also the celebrated Wingen oils with which the Australian contingent to the Soudan was amply provided. From time immemorial the lava powder found near the Mount Wingen crater has been used by natives and settlers as a remedial agent both for cattle and human beings. Mr. Charles Allen, M.P.S., has now, however, extracted an oil from the lava which is most popular throughout the colony as an application to sores and as an embrocation.

At the Exhibition, as in Australia, Victoria is the close neighbour of New South Wales. As a rising colony its importance cannot be exaggerated, and such statistics as are at our disposal indicate that it is also an exceptionally healthy colony. The illustrated handbook to Victoria prepared for the Exhibition states that in 1884 the marriage-rate equalled 7·63 per 1000, the birth-rate 30·49, and the death-rate 14·27. This is undoubtedly a remarkably low death-rate, but it cannot be compared with that of Europe, as the proportion of children in Victoria is much smaller. The fact that there is no winter, so to speak, in Victoria, must further contribute to the health of the population. Cattle are able to live in the field all the year round, though no sort of shelter is provided, and such climatic conditions must help to render physical existence easy. Winter is merely the more rainy season of the year, and snow is unknown. Among the various exhibits in this court may be noticed photographs of the Victorian Asylum for the Blind, some Australian filters and disinfectors, various mathematical and philosophical instruments, and a model of the quarantine station established at Point Nepean by the Central Board of Health for the colony. The Technological Museum is specially interesting, for we have specimens of 200 trees, the wood being polished, and the leaf, bud, and flower accurately painted on the smooth surface. The Acacia and the Eucalyptus are the principal families. From a medical and sanitary standpoint the importance of the latter is becoming better understood every day. Indeed, all Australian plants have already been subjected to extensive examination. It is not therefore the novelty, but rather the increasing appreciation of their virtues, that calls for notice. The acacias only contain the tan principle and certain gums soluble in water, such as occurs in the Indian acacia; but the products of the eucalyptus would repay closer study. For instance, the Atherosperma moschata cortex, to be found in the deep ravines of Victoria and Tasmania, is a useful sedative and diaphoretic. It contains a tonic bitter. The shepherds and others exposed to coughs and colds make constant use of the bark. As a tincture (four ounces of bark to twenty of rectified spirits of wine), it is taken on loaf sugar (not in water); while the oil has the reputation of exerting a specific influence in slowing the action of the heart when administered in small doses. For medical purposes generally, too much importance has been attributed to the eucalyptus globulus. The amygdalina species is preferable. It is a purer hydrocarbon, while the globulus is nearer to an oxycarbon. The odour also of the amygdalina oil is more aromatic and pleasant, and would therefore be more grateful when used as a disinfectant in a patient's room. The essential oil of the Eucalyptus amygdalina is largely employed as a styptic; it is sprinkled on a wet rag to relieve rheumatism; five or six drops on a piece of sugar may be taken as a sedative and in cases of colic. In fact, the medical uses of the eucalyptus are far more extensive than is generally known in England, though the Australians have for many years appreciated all these advantages. Mr. J. Bosisto, M.P., exhibits essential oils, gums, barks, and resins of this and other Australian trees, and particularly insists on the Succus eucalyptus rostrati, the red gum tree, as a delicate mucilaginous astringent, which he considers a safer and more effective remedy than either kino or catechu. Mr. Bosisto is not only the president of the Royal Commission for Victoria, but is an analytical chemist who has devoted more than twenty years to the study of the eucalyptus, both from a chemical and commercial point of view. His opinion on this subject is well worth considering, and we cordially join with him in the protest he is making against the wasteful destruction of trees in Australia. These trees aid materially in equalising the climate, while the aromatic odours they give forth are believed to be beneficial. Though there are 150 species, they all possess a volatile essence, but the yield varies greatly. Taking the eight principal types, Mr. Bosisto found that for 1000 pounds' weight of fresh leaves, the minimum yield of volatile essence was 7 fluid ounces, and the maximum 500 fluid ounces. Applying this calculation to the colony of Victoria, and reckoning according to the very lowest average, Mr.

Bosisto concludes that there are 9,730,500 gallons of an essential and volatile substance held at one and the same time in the eucalyptus vegetation. For the whole of Australia he puts down the amount at 96,877,440,000 gallons. This may be rough guessing, but nevertheless it helps us to understand how vast the volume of this wholesome evaporation must be; and its possible influence on the preservation of health is consequently obvious.

THE SCOTCH ELECTION OF DIRECT REPRESENTATIVES.

THE following correspondence has been sent us, and is worthy of consideration by all who wish to make representation of the profession a reality. The return of the President of the Faculty, as a reply to the demand of the profession for direct representation, would indeed be a *reductio ad absurdum*.

18, Carlton-place, Glasgow, Oct. 11th, 1886.

DEAR SIR,—In acknowledging receipt of your circular letter recommending Dr. Sinclair, of Dundee, as a candidate for the representation of the medical profession of Scotland in the General Council, I take advantage of the opportunity thus afforded of acquainting you with the success, so far, of our exertions in behalf of Dr. Morton, of spina bifida repute, whom many of us in the west are anxious to see promoted to a seat in the General Medical Council. We had our first meeting of committee last week, and the returns so far showed that about 300 members expressed a wish to serve on the committee, while a considerable number of busy men contented themselves with intimating their intention of voting for Dr. Morton. We are setting agoing an organisation for a complete and satisfactory canvass not only of our city but of the neighbouring towns and western counties, and we hope in the course of a few weeks to obtain the pledges of nearly half the entire constituency. We are pleased to find that the University people are not as yet putting forward a candidate, and we are in hopes that many of our friends in the east will help us in the west to carry our man. Even without them, however, we hope to win. I suppose the friends of Dr. Sinclair and of Dr. Bruce also are likely to fight to the end. Should you, however, come to find from your returns that you are not likely to win as we are here, instead of going to Dingwall with your support, I need hardly say it would find a hearty welcome from Glasgow and the west.

I am, dear Sir, truly yours,
(Signed) JAS. DUNLOP, M.D.,
President of Committee.

David Greig, Esq., M.D., President of Dr. Sinclair's Committee.

(*Dr. Greig's Reply.*)

Dundee, Oct. 12th, 1886.

DEAR SIR,—We have such confidence in Dr. Sinclair's prospects of success that the disposal of his support to any other candidate has never once entered our minds, and much less has it been, or is it likely to be, seriously entertained. Into your satisfaction that the University authorities have not started a candidate we most heartily enter; and it will give us equally great pleasure to learn that the considerations as to the direct representation theory, which have induced four prominent members of the profession in Edinburgh to decline invitations to come forward, have weight with Dr. Morton and his committee. These considerations mainly concern their University and Corporation connexions. Dr. Morton is an excellent man and would make an excellent corporation representative, but he has been too long identified with the governing body of the Faculty of Physicians and Surgeons of Glasgow, of which he is now President, to be acceptable to the great majority of the profession in Scotland. When he says in his address that if elected he will strive to get this number of direct members increased, I have no reason to doubt his sincerity. But I would venture to point out to you that his own election would be a very powerful argument in the hands of the parliamentary and other opponents of direct representation. It would obviously be open to them to say that the only effect of the concession had been to disturb the balance by increasing the representation of one corporation at the expense of the others.

I am, Sir, yours truly,
J. Dunlop, Esq., M.D. Glasgow. (Signed) DAVID GREIG.

ENTRANCE SCHOLARSHIPS, &c.

University College Hospital.—The entrance scholarships have been awarded as follows:—£100, W. A. Savage; £60, H. Tilley; £40, W. M. Stevens.

University College, Liverpool (Royal Infirmary School of Medicine).—The Holt tutorial scholarships of £100 each for one year have been awarded to A. W. Collins and J. E. Gemmel; and the Roger Lyon Jones scholarships of twenty guineas per annum for two years to H. A. Burrowes and A. J. Chalmers.

University of Durham College of Medicine, Newcastle-on-Tyne.—The Charlton Scholarship, value £35, the Dickinson Scholarship of £15, and a gold medal have been awarded to B. G. Sumpter; the University Scholarship, of £25 per annum for four years, to Raymond Henry Shaw; the Gibb Scholarship, of £25, to M. M. Bowlan; and the Tulloch Scholarship, of £20, to A. E. Cope.

School of Physic in Ireland.—The Medical Scholarship, of £20 per annum, tenable for two years, for anatomy and the institutes of medicine, has been awarded to Henry C. Drury, B.A.; and that of £20 per annum, tenable for two years, for chemistry, physics, botany, and comparative anatomy, to Alfred R. Parsons.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Salford Urban District.—Not only did Salford, in common with most large towns in England, experience an exceptionally low death-rate in 1885, but during the five years which have elapsed since 1880 the average annual rate of mortality in the borough has been lower than the average rate in the five years which preceded that date by not less than 4·5 per 1000. When the Public Health Act, 1875, was passed the rate of mortality per annum averaged 28·4 per 1000, and in Salford proper, the oldest part of the borough, it averaged 31·5 per 1000. Since then the borough has progressed considerably in matters relating to health. The small-pox epidemic of 1875-76 led to the establishment of a hospital for infectious diseases; then came large demolitions of bad house property; the scavenging arrangements and the ultimate disposal of refuse were greatly improved; food-supplies were carefully looked after with the aid of the Adulteration of Food and Drugs Act; the provisions of the Dairies, Cowsheds, and Milkshops Order brought nearly 700 establishments connected with the milk-supply under supervision; and many other improvements were carried out. The result is one as to which Dr. Tatham may be congratulated, for the sanitary administration of a borough containing some 200,000 people is associated with numberless difficulties. During 1885 there were reported under the provisions of the Notification Act 632 cases of scarlet fever, 205 of enteric fever, 54 of diphtheria, 32 of typhus, 15 of puerperal fever, and 11 of small-pox. The conditions affecting the incidence of these several diseases are discussed in the report; and, speaking generally of the diminution which has taken place in England and Wales in the mortality from infectious diseases, it is pointed out that it has been mainly felt in the large towns. Thus in London it amounted to 17 per cent., whereas in the rural districts it was only 5·5 per cent., and in the small towns only 2 per cent. This Dr. Tatham regards as implying that although infectious diseases still have a tendency to excessive prevalence in densely crowded districts, yet the sanitary efforts for their repression are commonly more effectual in great towns than they are in smaller communities. But as to diarrhœa, Salford continues to occupy a position of unenviable notoriety. The borough is grouped with Preston and Leicester as possessing the highest diarrhœa mortality amongst English towns, and unfortunately her position in this respect has not yet indicated any tendency to improvement. As regards the isolation of the infectious fevers, considerable progress has been made in connexion with the steady improvements which the Corporation have, at great cost, made in the hospital provision. Taking the nine years, 1876-84, during which such accommo-

dation has been available, the proportion of admissions to hospital to the number of deaths in the borough was as 1·04 to 1, whereas in 1885 it amounted to 5·3 to 1; figures which conclusively show that the people of Salford do increasingly appreciate the great safeguard against infection which proper isolation in hospital affords. Many other matters are discussed in the report under consideration; they show how large an amount of skilled attention is devoted year by year to the improvement of public health.

Sunderland Urban District.—In his last quarterly report on this borough Dr. Harris refers to a steady general improvement in the mortality returns, and he points to the fact that during the past eighteen months the death-rate has been lower than at any period for twenty years. But diarrhœa was more than usually prevalent during the past quarter. No special local sanitary conditions were found to be associated with this occurrence, whereas, according to the report, it was elicited that the greatest mortality occurred among children under twelve months of age who were fed from the bottle. Out of 77 deaths of children at this age, 60 were bottle-fed and 17 were suckled. Whilst this fact is prominently put forward, no relaxation is allowed to take place in securing additional cleanliness of air and soil in the districts where diarrhœa and other preventable diseases occur.

Preston Urban District.—Diarrhœa was fatally prevalent in Preston during the end of August and the beginning of September. The high temperature which prevailed is reported by Dr. Piking to have been accompanied by diminished air movement, and the result was soon felt in the poorer and more confined parts of the town. And even when the air temperature fell considerably, the ground temperature still remained high, and the improvement as regards diarrhœa prevalence was in consequence only slight. In all, there were during five weeks 88 diarrhœa deaths. Of these, 6 only occurred amongst adults, whereas 71 were in children under twelve months.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5090 births and 3220 deaths were registered during the week ending Oct. 30th. The annual death-rate in these towns, which had been 18·9 and 19·3 per 1000 in the preceding two weeks, declined last week to 18·5. During the first four weeks of the current quarter the death-rate in these towns averaged 19·0 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 11·9 in Derby, 13·5 in Sunderland, 13·9 in Brighton, 14·6 in Salford, and 15·3 in Portsmouth. The rates in the other towns ranged upwards to 24·4 in Norwich, 24·5 in Manchester, 25·4 in Cardiff, and 30·9 in Wolverhampton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding seven weeks from 1202 to 438, further fell last week to 401; they included 130 from diarrhœa, 84 from scarlet fever, 72 from measles, 63 from "fever" (principally enteric), 35 from diphtheria, 17 from whooping-cough, and not one from small-pox. No death from any of these principal zymotic diseases was recorded last week in Bolton; whereas they caused the highest death-rates in Norwich, Nottingham, Liverpool, Halifax, and Wolverhampton. The greatest mortality from measles occurred in Leicester, Wolverhampton, and Halifax; from scarlet fever, in Manchester, Bristol, Liverpool, and Huddersfield; from "fever," in Preston, Nottingham, and Portsmouth; and from diarrhœa, in Norwich, Salford, Cardiff, Nottingham, and Wolverhampton. The 35 deaths from diphtheria in the twenty-eight towns included 23 in London, 2 in Norwich, and 2 in Manchester. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 3 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 223 and 290 in the preceding two weeks, further rose last week to 295, but were 80 below the corrected average. The causes of 84, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bolton, Wolverhampton, and Derby. The largest proportion of uncertified deaths were registered in Sheffield, Huddersfield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·5 and 18·2 in the preceding two weeks, rose again to 18·6 in the week ending Oct. 30th; this rate was 0·1 above the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·9 and 15·1 in Edinburgh and Dundee, to 19·9 in Paisley and 23·3 in Glasgow. The 460 deaths in the eight towns last week showed an increase of 10 upon the number in the previous week, and included 28 which were referred to whooping-cough, 24 to scarlet fever, 22 to diarrhœa, 6 to diphtheria, 2 to measles, 1 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 83 deaths resulted from these principal zymotic diseases, against 88 and 72 in the preceding two weeks. These 83 deaths were equal to an annual rate of 3·4 per 1000, which was 1·1 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 25, 21, and 17 in the previous three weeks, rose last week to 28, of which 24 occurred in Glasgow and 3 in Edinburgh. The deaths from scarlet fever further rose from 12 and 17 in the preceding two weeks to 24, and included 13 in Glasgow, 8 in Dundee, and 2 in Edinburgh. The 22 deaths attributed to diarrhœa showed a further decline from the numbers in recent weeks; 7 were returned in Glasgow, 5 in Edinburgh, and 4 in Dundee. The 6 deaths referred to diphtheria, although exceeding recent weekly numbers, were below the average for past years; 4 occurred in Glasgow and 2 in Edinburgh. The solitary death referred to "fever" was recorded in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 98 and 79 in the preceding two weeks, rose again last week to 96, but were 21 below the number in the corresponding week of last year. The causes of 61, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 22·5 and 20·5 per 1000 in the preceding two weeks, rose again to 21·9 in the week ending Oct. 30th. During the first four weeks of the current quarter the death-rate in the city averaged 22·0; the mean rate during the same period was 17·1 in London and 16·8 in Edinburgh. The 148 deaths in Dublin last week showed an increase of 9 upon the number in the previous week, and included 9 which were referred to diarrhœa, 10 to scarlet fever, 4 to "fever", and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus 23 deaths resulted from the principal zymotic diseases, corresponding with the number in the previous week; they were equal to an annual rate of 3·4 per 1000, the rates from the same diseases last week being 1·8 in London and 2·5 in Edinburgh. The fatal cases of scarlet fever, which had been 2 and 7 in the previous two weeks, further rose last week to 10, and exceeded the number in any previous week of this year. The deaths referred to diarrhœa, on the other hand, had further fallen to 9, from numbers declining in the preceding six weeks from 29 to 10. The 4 deaths referred to "fever" were within one of the number in the previous week. Five inquest cases and 3 deaths from violence were registered; and 28, or nearly a fifth, of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed an increase upon the numbers in the previous week. The causes of 20, or nearly 14 per cent., of the deaths registered during the week were not certified.

VOLUNTEER MEDICAL STAFF CORPS.—The members of this corps recently held their competitions in waggon and stretcher drill, bandaging, and the application of the triangular bandage. Surgeon-Commandant Cantlie was in command, assisted by Surgeon Rees Hall, the adjutant. The prizes for waggon loading were awarded to a section of Surgeon-Major Platt's (St. Thomas's Hospital) company, and for field stretcher drill to Surgeon Squire's (University College Hospital) company. The other series of competitions were postponed. Surgeon Beevor, M.D., of the Scots Guards was the judge.

Correspondence.

"Audi alteram partem."

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—The correspondence in your columns to-day and previously seems to reveal two things: 1st, that the long-standing feud between the universities and the corporations is being fanned into a flame; and, 2nd, that Dr. Bruce may now be said to be announced as the nominee of the universities. Those who countenance the former unfair proceeding are obscuring the main question before the profession. Those who give countenance to the latter are showing an unaccountable degree of magnanimity, especially if they have read Dr. Bruce's address or lecture to the Northern Counties Medical Association. This address, indeed, makes short work of university medical monopoly, and knocks down almost all the hoarding that keeps the classes of inefficient professors crowded with reluctant and neglected students. A graduate, who has not the courage to sign his name, writes in an injured strain because there is no Edinburgh candidate in the field. Pray whose fault, positive or negative, is it that this is the case? The general practitioners of Scotland ought to be, and according to present appearances are to be, represented by one who has had a long enough training in the wants and woes of the profession to fit him for legislating in their behalf; and, *certes*, he is too well posted up in the subject to suggest either regulations that have been in force long ago, or regulations that are never in the least likely to come into force.

Dr. Morton is the chosen candidate of the most populous portion of Scotland, and this choice rests upon the knowledge that he has long been the manly and independent advocate of the rights of the general practitioner, with whom he has identified himself far more than with any corporation. True it is, that he has been a Fellow of the Faculty for many years (and is now President, it may well be added, by the voice of the general practitioner), but that does not alter his position, nor is it likely to modify his politics one whit. Nay, he evidently has no desire to sever his connexion with the Faculty, even though that body, under certain influence, treated him rather coldly for a time on account of his politics. He has had the good sense to advocate free trade in teaching and the removal of the anomalies that are always apt to grow upon monopoly. As to the objection, whether real or not, that is made about connexion with a corporation, it need only be remarked that if a man is within hail of a corporation, he is surely not to avoid it lest at any time he should aspire to represent his fellow-practitioners at the General Medical Council. Is he to debar himself from having the corporate intercourse with them whereby he can best inform himself about their needs? or is he to allow his mind to be a *tabula rasa* till the combined wisdom of the Council has written something upon it?

The proposal that two of the candidates should join their forces is an admission that they are or may become of the same colour, and an admission of their individual weakness and of Dr. Morton's strength. If this strategic movement is prompted by the intention to use them merely as pawns in the game, the profession will know how to resent the manipulation by a transposition of votes that may rather astonish the movers. I am, Sir, your obedient servant,

Glasgow, Oct. 22rd, 1886. J. PIRIE, M.D.

To the Editor of THE LANCET.

SIR,—As a member of the British Medical Association, I refuse to support any candidate who attempts to use our machinery or official influence for his own purpose, since in general meeting assembled, at Brighton, we distinctly declined to take any part in the selection of candidates. Had it not been for the unauthorised actions of those members of our Council who, after the refusal of the general meeting, persisted in the attempt to commit the Association to interference in the election, I could gladly have supported Sir B. Foster, but I cannot in any way sanction the nominees of a committee acting in opposition to the expressed will of the general meeting. We have been informed that this committee is unofficial, self-appointed, and not identified with the Association. We are now informed that the Council has passed a resolution in favour of *two of its own members* who are the candidates of the committee. Is that act also "unofficial and not identified with the Association," but only another attempt to delude members into a "misconception"?

I am, Sir, your obedient servant,

HENRY W. WILLIAMS, M.D.

Chapel-place, Cavendish-square, W., Nov. 2nd, 1886.

To the Editor of THE LANCET.

SIR,—I wish to draw the attention of all Poor-law medical officers to the fact that one of their own number, Mr. D. B. Balding, is now a candidate for their direct representation at the General Medical Council. This gentleman is one of the vice-presidents of their own special corporation, and for many years past has worked hard for their cause; therefore I hope they will now acknowledge his past services by giving him their best support.

I remain, Sir, your obedient servant,

FRANCIS A. DAVEY, M.R.C.S.E., L.S.A.

Barkway, Herts, Oct. 30th, 1886.

To the Editor of THE LANCET.

SIR,—I am sorry to find that my address to the registered medical practitioners of England and Wales, which was duly forwarded for insertion in your advertising columns of last week did not appear, and, as I am informed, it was "crowded out." Of this I make no complaint, as I suppose it was occasioned by ordinary business pressure. I trust, however, that you will allow this letter to appear in your next, by way of explanation, as much surprise and disappointment has been occasioned by the non-appearance of the address last week.—I am, Sir, yours very obediently,

Royston, Nov. 1st, 1886. D. B. BALDING.

*** The address referred to, which arrived too late for insertion in our last issue, will be found in the advertising columns of our current number.—ED. L.

POLLUTION OF THE THAMES.

To the Editor of THE LANCET.

SIR,—I read your excellent article of the 9th inst. on the above subject with much interest, but it is impossible to separate the subject and to isolate, as it were, any portion. The subject of sewage utilisation must be considered as a *whole*, and the following questions are all intimately identified—viz., "Health of Towns," "Pollution of Rivers," and "Utilisation of Sewage Matters." So far the sanitary condition of London and all other large cities has been adversely affected by the modern underground system of cesspool drainage, and the rivers have been fouled, while the excreta of the population have not in one single instance been utilised, and the agriculturists have been deprived of the finest fertilising agent for arable land yet discovered. The truth is, it is not possible, nor will it ever be, to utilise the excreta by any process whatever *beyond* the sewer's outfall, unless such an arrangement can be made with the heavens as shall admit of a regular and constantly repeated rainfall; and it is a sad reflection that many millions sterling have already been wasted in vain attempts to overcome the difficulty and to solve what is now known as "the sewage problem." When the Commission sat over which Lord Bramwell presided, it was said that no subject but the pollution of the Thames could be considered; but how the Commission could deal with the pollution of the Thames without taking into consideration the question of the drainage of the metropolis I am at a loss to understand, since the pollution of the Thames during the last forty years has occurred in consequence of the discharge of the soil from a quarter of a million waterclosets of London through the drains and sewers into the river. The arrangement by which this evil has been produced has been adopted and carried out during the period above named, and it cannot be denied that it is altogether hopeless to attempt to purify the Thames by any process whatever *beyond* the sewer's outfall, unless the *solid* portion of the excreta is intercepted at the fountain head before it has been placed under the control of the rainfall, and with this, even, it will be necessary to convey the liquid portion of the excreta, with the water from the

watercloseta, in small pipes separated entirely from the rainfall and other surface sewage. The *excreta* sewage, in fact, *must* be kept separate and distinct from the *rainfall* sewage; no process whatever, whether it be filtration, subsidence, deodorisation, irregular or intermittent downward filtration of the effluent which may escape from any sewage works, can affect the question in the least, since it is not the effluent which is the cause of the pollution of the rivers, but that portion of the excreta, almost the entire portion, which is washed from its hiding-place in the house drains during the rainfall, and during the rainfall alone, and escapes from the sewers through the storm outlets into the rivers; it is, I say, through the storm outlets that the sewage of all large cities finds its way into the rivers, avoiding, as it does, and as it always will do, *any* works which may have been constructed for the pretended purpose of purification and utilisation.

By the kind permission of Sir J. Bazalgette, I have been over the sewage works (London) at Bow, and I have been in the sewers and over the sewage works at Birmingham, Croydon, &c., and with the exception of the latter place, where some portion of the excreta may be utilised in a rough and ready manner, scarcely any utilisation of excreta *whatever* takes place. Nor is the evil of the modern underground cesspool system confined to our cities, where it propagates septic and zymotic diseases in every direction, nor to the pollution of the rivers, nor to the waste of the finest fertilising agent known, but the ocean itself is suffering to an alarming extent, which is being fouled by the wretched system all round the coast, and the fish are either being driven away from our shores or rendered unfit for human food in consequence of a consumption by them of a material—human excreta—which, if it were utilised by our farmers on their *arable* land, would produce crops of wheat, barley, oats, &c., such as would gladden the hearts of our depressed agriculturists.

In the metropolis at this moment there are no less than 4000 miles of these underground elongated cesspools, under every house and every street; but these cesspools being out of sight, they are not easily recognised until some foul odours are detected, and an epidemic of typhoid, diphtheria, or diarrhœa occurs, or, what is still more common, a prevalence of septic diseases, such as occurred at Marlborough House, the House of Commons, the Horse Guards, &c., and, if my memory does not fail me, at the Local Government Office itself, which had been so recently constructed with every pretended sanitary improvement of the modern type; and if an examination were made, there would be found scarcely a single house in the metropolis in a sanitary condition or anything approaching to such a state. With the exception of small-pox, where has been the diminution of zymotic disease? while septicæmia has been largely increased. There has, without doubt, been a diminution, and a very large diminution, in the death-rate from phthisis, which formerly caused the deaths of 11 persons per 1000 of the population of the metropolis; but the diminution which has taken place has been due to the discovery of the stethoscope, which has enabled the physician to detect and to treat phthisis in its earliest stage, and not to sanitation in any of its pretended forms.

Another reason why preventable disease ought to be less prevalent and the death-rate be diminished, especially in large cities, is that the area over which people now live is greatly extended. In former years, before railways were made, Londoners lived in London and brought up their children there; whilst at the present time such people, both rich and poor, have removed into the surrounding rural districts, and they have taken their children with them, with the inevitable effect of increasing the rural death-rate and of diminishing the town death-rate; and since the death-rate of children below one year old is from sixteen to eighteen times greater than that of adults, it is obviously unfair and misleading to compare the death-rate of the metropolis at the *present* time, when there is a very small proportion of children to adults in the population, to a period of, say, thirty years ago, when there was a very large proportion of children in the population.

I have been compelled to refer to the sanitary condition of the metropolis in connexion with its drainage, and especially in connexion also with the pollution of the Thames, since it is impossible, as I said at the beginning of my letter, to separate the one from the other. Let us beware! While we are polluting the Thames and other rivers of the United Kingdom, we are at the same time, and by the same process, contaminating the atmosphere of the houses and streets of the metropolis and other large cities by a system which can only be described as the most injurious, the most wasteful, and the most abominable that was ever devised by the human mind.

I am, Sir, yours truly,

Birmingham, Oct. 22nd, 1886. E. CHESSHIRE, F.R.C.S.

INDUCTION OF LABOUR IN CASES OF ALBUMINURIA IN PREGNANCY.

To the Editor of THE LANCET.

SIR,—I am fortunately able to set at rest any doubts which Dr. Horrocks may have as to the activity of the specimens of pilocarpine and jaborandi used in the case reported by Dr. Cullingworth. Both preparations which were used on that occasion are known to have been active, and as both of them are still in the hospital, I have had an opportunity of again testing them since reading Dr. Horrocks' letter, and find them still active. Yesterday I injected under the skin of a patient one-third of a grain of the pilocarpine used in the case referred to. Ten minutes after the injection the face became brightly flushed, and profuse perspiration and salivation followed. I myself also took, yesterday, a drachm of the same fluid extract of jaborandi as that administered in the case under discussion, the dose also being similar, and marked diaphoresis and salivation ensued. I have thus met Dr. Horrocks' objection that the preparations used were probably inert. Dr. Horrocks begs the question when he says that if the drug produces marked diaphoresis then good will follow. The point is, that in this case a dose, which is usually recognised as a full one, and which is sufficient to produce striking physiological effects on other patients and on healthy persons, failed to produce marked diaphoresis or other beneficial effect on our patient. This is surely a fair trial. Dr. Horrocks says that the dose of one-third of a grain ought to have been repeated in fifteen minutes. Considering the weak state of the patient and the depressing effects often produced by the drug, we did not feel justified in repeating the dose, nor am I inclined to think would Dr. Horrocks himself have cared to do so, judging from the warning tone of the last paragraph of his letter.

As regards the imputed ecbolic action of pilocarpine, Dr. Horrocks appears to be guilty of hasty generalisation. In the first of his cases (THE LANCET, June 13th, 1885), labour came on a week after pilocarpine was discontinued; but he thinks it possible that this drug set up the uterine contractions. In his second case the patient had strong convulsions, and labour seems to have commenced before the exhibition of pilocarpine. The os dilated rapidly after pilocarpine was given, and on this ground Dr. Horrocks remarks that "it would appear that pilocarpine must be looked upon as an ecbolic." As a matter of fact the weight of evidence lies quite on the other side, as is shown by the researches of Dr. Hyernaux (*Lond. Med. Record*, January, 1879), and by cases reported by Mr. Clay, Dr. Kleinwachter, and others. Considering the well-known double relationship which exists between general convulsions and uterine contractions, one is bound, I think, to be doubly cautious in drawing inferences as to the oxytocic action of drugs in cases of eclampsia. I am, Sir, yours faithfully,

ARCHIBALD DONALD.

St. Mary's Hospital, Manchester, Nov. 2nd, 1886.

To the Editor of THE LANCET.

SIR,—I have but little to add to the foregoing letter. Dr. Donald effectually disposes of the suggestion as to the inferior quality of the drugs administered. Both Dr. Horrocks and Dr. Murphy (THE LANCET, Oct. 16th) write as though they held a brief for pilocarpine, and both, when the anticipated result fails to follow the exhibition of their pet drug, fall back on the stock argument that the specimen used must have been bad. We have surely had enough of this method of attempting to prop up a weak cause in the notorious instance of Chian turpentine. As to the other and more curious suggestion, that the remedy ought to have been injected every quarter of an hour, I can only hope that no one may be tempted to act upon it. I assure Dr. Horrocks that the sole object I had in view in reporting my case was to record the fact that in a typical case of albuminuria in pregnancy pilocarpine failed to give

relief. All that this proves is that this drug, potent as it is, is not infallible any more than any other diaphoretic, and that there still remain cases of albuminuria in pregnancy where the induction of premature labour becomes the proper and only efficient mode of treatment.

I am, Sir, yours faithfully,

Manchester, Nov. 2nd, 1886. C. J. CULLINGWORTH, M.D.

TREATMENT BY MASSAGE.

To the Editor of THE LANCET.

SIR,—There is one statement in Dr. Playfair's letter on massage which, I think, should not go unchallenged. It is contained in the sentence: "The plain truth, stripped of verbiage, is that massage is nothing more than a vicarious way of giving exercise to patients who cannot take it themselves." Now massage may be all this, but it is something more; and further on in his letter Dr. Playfair seems to admit this, for he says "that massage is capable of doing much good in conditions other than those for which I have employed it is perfectly likely." It is too late in the day to say that massage is "likely" to do good in other cases than those for which Dr. Playfair employs it. We know it for a fact. To take a single example from many: So long ago as 1876 Mosengeil showed by experiment[1] that if he injected indian ink into the knee-joints of a rabbit and applied massage, the particles of iuk showed themselves very shortly in the region of the vessels and the interstices of the muscles, and the swelling rapidly diminished. The pure mechanical operation of simple massage is thus at one and the same time pain-diminishing and pain-removing. Massage has thus an antiphlogistic action. This experiment, the details of which may be found in the publication referred to, established the mode by which exudations in joints and muscles were removed through massage. Now, when massage or simple kneading is employed in cases of joint or other effusions with good results, can it be called "nothing more than a vicarious way of giving exercise to patients who cannot take it themselves"? Should it not rather be regarded as a valuable curative agent? This is only one case out of many in which simple massage has been of proved utility. As for true massage—including, as it does, kneading, active and passive exercises, nerve, vibration, &c.,—the list of diseases and minor ailments for which it may be used is a large one. It may be that many cases, as Dr. Playfair suggests, are subjected to massage which are unsuitable; but what medicine, operation, or mode of treatment ever existed or gained repute of which the same could not be said? It is proved beyond doubt, I think (1) that even simple massage is more than a vicarious way of giving exercise; (2) that the system of manual treatment is a valuable curative agent in many diseases.—I am, Sir, yours truly,

Stranraer, Oct. 25th, 1886. THOMAS EASTON, M.A., M.B.

To the Editor of THE LANCET.

SIR,—The discussion as to the length of time required to learn massage, or, as I much prefer to call it, medical rubbing, will greatly help towards the settlement of the question.

At the Worcester meeting of the British Medical Association (1882) I read a paper on Medical Rubbing, which was published in the journal the following week, and after four years' further experience and teaching, perhaps I may be allowed to express an opinion. Dr. Sturges and Dr. Playfair are right when they say that the manipulations practised as part of the Weir Mitchell treatment can be learnt by an apt pupil in a few lessons, but they are wrong in supposing that all the "art and science" of medical rubbing is embodied in these elementary proceedings. Dr. Murrell is right when he says that the field of usefulness that lies before a skilled rubber is a vast one, but he is wrong in saying that it takes two years to acquire the science and practice of massage. I also submit that we are not justified in using technical terms drawn from a foreign language when we can find equivalents in our own mother tongue. Let a pupil be taught (*mimus* the French terms) medical rubbing in all its many branches, including muscle-beating, muscle-rolling, deep thumbing, active movement, and the manipulations for the treatment of rheumatoid arthritis, infantile palsy, writers' cramp, tennis elbow, &c., still he cannot possibly spend two years over the course. A period of three or four months will amply suffice if he will ever make a rubber, and a lifetime will be too short if he has not the natural gifts that are essential to success. I quite agree with Dr. Easton, that it is quite time that a course of training for medical rubbers was organised and certificates granted. The number of so-called rubbers (who should be termed bruisers) that are abroad is astonishing. I have seen several patients black and blue all over after being treated by some of the fraternity, and they have prejudiced many medical men against a most valuable means of treatment. The sooner, too, that many utterly unsuitable persons who are "learning to rub" are sent about their business the better for themselves and for their clients. The handsome incomes (nay, fortunes) now being earned by medical rubbers show that it will amply repay those who wish to learn properly for incurring the needful expense.

I remain, Sir, yours faithfully,

J. FLETCHER LITTLE, L.R.C.P. Ed.

Ben Rhydding, Oct. 25th, 1886.

*** Our space will not allow of the publication of more letters on this subject.—ED. L.

INFANT FEEDING.

To the Editor of THE LANCET.

SIR,—In answer to Mr. Parker's letter in your issue of Oct. 30th, permit me to say that the views expressed by me in my last letter were written with the knowledge that they are adapted for general use, and not for "individual cases."

The principles of feeding that have been advocated by me in this correspondence constitute, I thoroughly believe, the highest and the best form of feeding yet known for children who must be reared from birth by hand. I wish to be clearly understood on this point, and I offer this opinion as the result of my own experience, gained not from "sick and mismanaged" children only, but from those also who were known by me at their birth, and who have been reared by what seems to me to be the proper method from that time onwards. It is possible that Mr. Parker may not have this advantage; at least, the inference is a fair one from the passage from which the above extract is quoted. I cannot recede from the statement made by me, that half cow's milk and half water is much too strong to commence with at the time of birth, and that failure is courted by its adoption. Some children may escape with less inconvenience than others; but very few, if any, are likely to escape altogether, without some upsets which might be avoided, but which are so often accepted as the inevitable consequences of infancy. Dyspepsia to a greater or less degree is frequently, in my judgment, the result of such rash and intemperate use of cow's milk probably much oftener than it is "congenital."

Mr. Parker, in speaking of infants who have thriven upon half milk and half water, leaves us to infer that this feeding was started at the time of birth, because my remarks upon Dr. Thurstan's case, which he quotes, were distinctly in reference to the first week in life. I am disposed to treat the pancreas and salivary glands with some respect, and would remind Mr. Parker that at the third month they are still rudimentary. This fact from his standpoint is of no importance. When infants are reared by "mixed" feeding, liberties may be freely taken with them, which children who are fed without the help of breast milk are quite unable to tolerate. This fact may help to explain the following passage from Mr. Parker's letter—viz., "for few, if any, children of the poorer classes are brought up from infancy onwards without farinaceous food, and enjoy the most vigorous health notwithstanding." The children of the poor are much more commonly fed in the "mixed" manner than in any other, and it is a fallacy to suppose that the wealthy matron is more inclined or able than her poorer sister to give the natural food to her offspring. For purposes of economy the poor adopt it, if from no higher motive. In this town, owing to the chief work requiring much female labour, children get farinaceous feeding entirely at an early date, and our death-rate and out-patient rooms show the results.

I can hardly, I fear, endorse Mr. Parker's statement that the progeny under such circumstances is a healthy one. Mr.

Parker very emphatically declines to be convinced that any evils can result from the use of farinaceous food. We must agree to differ therefore. I look upon the use of farinaceous food to divide the curd as at least an unnecessary expedient, which can be entirely done away with if a cow's milk diet is suitably adjusted and properly given. I am glad that Mr. Parker agrees with what my letter contains bearing upon the mode of administration of food; but, from the tenour of his remarks, I do not gather that he, with myself, recognises the fact that teachers and practitioners do not attach much importance to those details. How many men in practice will tell us the quantity per meal an average child will take at a given age, or what strength of milk preparation is most likely to be well digested at the same age? This is not taught in the schools, and I know of no book, except the last edition of my friend Dr. Goodhart's, which attempts to make complete suggestions on the subject. It may be a common practice in some counties to stock cows so early as represented by Mr. Parker; I am led, however, to believe that it is not the general custom. I have heard too often the frank expressions of the typical matron, but her evidence, even when backed by the "healthy family," is not always reliable.

I am, Sir, yours truly,

Nottingham, November, 1886. LEWIS W. MARSHALL, M.D.

CHIAN TURPENTINE IN THE TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 16th, Dr. J. Clay has published an account of the successful treatment by Chian turpentine of a case of epithelioma of the tongue which was under our joint care, and, with your permission, I should like to supplement this by the narrative of another case, with a like result from the same treatment.

Mrs. G——, aged forty-nine, sent for me in Oct. 1883. She had been suffering from occasional and severe hæmorrhage from the vagina for some five or six months, accompanied with but little pain and slight colourless discharge in the intervals of the hæmorrhages. On examination per vaginam, the os and cervix uteri were replaced by an extensive ulcerating surface of a decidedly malignant character. The hæmorrhage was soon arrested by cotton-wool plugs saturated with glycerine of tannin, but it frequently recurred, and between its arrest and reappearance a purulent discharge, with the characteristic cancerous odour, was observed. In the hope that some alleviation of the symptoms might result, I gave her the Chian turpentine pills according to Dr. Clay's formula, and she took them for some weeks. However, there was no improvement in any way, and it was decided that Dr. Playfair should see her in consultation. He did so, and confirmed my diagnosis of cancer, considering it to be of the medullary form. His prognosis was that "she could not last many weeks." He advised the carrying out of Dr. Clay's treatment in its entirety—viz., the Chian turpentine mixture, and the insufflation of charcoal and tannin per vaginam. The treatment was rigidly carried out, mainly by my coadjutor, Mr. W. A. Fox. Instead of losing ground, notwithstanding the persistence of the discharge and occasional hæmorrhage, her strength was maintained during the next few months, when all her symptoms gradually abated. The treatment, however, was fully continued for nearly a year, at the end of which time she was practically cured, and about twenty months from the time Dr. Playfair first saw her, he again examined her, and said that she was perfectly cured, to his extreme astonishment. She remains without a vestige of the disease at the present moment.

I am tempted, with your permission, to add a note respecting a case of long-standing cancer of the breast in a woman aged forty-eight, who had been an out-patient at a metropolitan hospital, and was discharged as unfit for operation. The left breast was destroyed down to the ribs, and its place taken by a superficial cancerous ulcer surrounded by nodules of cancer. She took Dr. Clay's remedies for some months, and then discontinued them on account of the expense. I have seen her to-day (October 16th) and find that the nodules have much diminished in size, that all her pain had disappeared, and that she has gained and is gaining flesh.

May I suggest as one of the reasons of the failure of this treatment as carried out at the Middlesex Hospital, and by medical men generally, is an insufficiently long trial of the remedies—in fact, too great haste in discarding a treatment which does not give immediate results.

I remain, Sir, your obedient servant,

New Barnet, Oct. 20th, 1886. G. W. F. BURY, F.R.C.S. (Exam.)

To the Editor of THE LANCET.

SIR,—Dr. Clay reports three more cases of cancer cured by Chian turpentine! The drug was tried in the cancer wards of Middlesex Hospital when Dr. Clay first recommended it, and declared to be utterly useless. In the West Norfolk and Lynn Hospital it was tried at the same time, and, as far as I could see, without the slightest influence on the course of the disease. For the credit of the profession and for the sake of humanity the claims of Dr. Clay for Chian turpentine in the treatment of cancer ought either to be repudiated or reconsidered.

I am, Sir, yours obediently,

King's Lynn, Oct. 21st, 1886. WM. DALE, M.D. Lond.

To the Editor of THE LANCET.

SIR,—The transposition of the word "mixture" in my paper published in THE LANCET for October 16th, has caused me to have several letters asking for an explanation of the incongruous sentence. In the second column, page 720, line 41, the sentence should read: "He was ordered the following: Eight ounces of Chian turpentine mixture (Southall's)," &c. By allowing this explanation to appear in THE LANCET, you will oblige Yours, &c.,

Birmingham, Oct. 30th, 1886. JOHN CLAY.

VITAL STATISTICS OF READING.

To the Editor of THE LANCET.

SIR,—I observe that you have published a paper read by my friend Mr. Barford, of Wokingham, at the Reading Pathological Society, in which he contrasts certain statistics as regards Reading with those of other districts.

Mr. Barford has taken the figures of the Registrar-General on "registration districts," and has thus contrasted the Reading district (which is, as regards population, almost identical with the borough) with scattered rural districts, containing only villages and towns of much less size than Reading, but having a far greater area in acres. Thus he has contrasted the following "registration districts" with Reading: Bedford registration district, 97,406 acres, with a population in 1881 of 42,932 (including the small town of Bedford); Bradfield, 64,700 acres and 18,000 people; Newbury, 44,695 acres, 21,300 people, and several districts of a similar character, none containing any large town like Reading; or in other words, districts ranging from about 40 to 150 square miles, many of them sparsely populated, were contrasted with the Reading Union, populated by 43,494 people, of whom (in 1881) 42,050 lived in the borough on about three square miles, or 2094 acres. If the correct statistics were taken for the borough or urban sanitary district of Reading, it will be found that the reduction in the general death-rate has been from 24 per 1000 in 1841, to 18 per 1000 (imported deaths in hospital being excluded) taken on the average of the last ten years (1876 to 1885), and for this period the birth-rate has been 36·6 per 1000, and the infant mortality 132·5 per 1000 births. Mr. Barford says, "Out of 1000 infants born in Reading, no less than 139 die during the first year of their existence." This language would seem to imply that is the case at the present time, whereas in the last five years the infant mortality for the borough has been 121·2 per 1000 births, and for the ten years (1876 to 1885) 132·2. Dividing this period into two periods of five years, the saving of infant life on the last five years, as contrasted with the first five years, has been 22·6 per 1000 births. This reduction, taken with reference to the total number of children born in each year, would give an annual saving of the lives of 34 children. Mr. Barford does not state what he has taken as a standard of excellence for infant mortality, but simply says, "The lives of at least 40 infants might be saved every year." Therefore, during the last five years (1881 to 1885) this has very nearly been accomplished. I cannot follow Mr. Barford when he states that Bedford resembles Reading, and that as the population

of the Bedford registration district was 42,060 and Reading 38,006, the comparison should be a little in favour of Reading." Apparently, he would seem to think that the registration district of Bedford is coincident with the town of that name, whereas Bedford "registration district" covers 150 square miles, and in 1881 had a population of 42,932, whilst the Reading "registration district" covers seven and a half square miles, and in 1881 had a population of 43,494, out of whom 42,050 resided in the borough on three square miles. The small town of Bedford, which is included in the above district, had in 1881 only 19,532 people, and in ten years had only *increased* 2681 in population, but Reading had increased 9736. A comparison between th respective town or urban districts would have been to more purpose, rather than one based on the respective registration areas or unions which differ so widely, and it is to be regretted that the returns of the Registrar-General do not refer to urban and rural sanitary areas, as at the present time it is only the medical officers of health who can give the rates for their respective sanitary districts. Although I should be very pleased to see the infant mortality of this borough still further reduced, I think, for the credit of the town, the improvement that has already taken place should be recorded.

I am, Sir, yours faithfully,

JOHN SHEA, M.D., &c.,
Medical Officer of Health, Reading and Wokingham Urban and Rural Sanitary Districts.

Oct. 20th, 1886.

STATISTICS OF OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—I owe to the courtesy of the secretary to the Royal Medical and Chirurgical Society the receipt of an abstract of a paper read by Mr. Knowsley Thornton on the 26th ult. In that abstract will be found the following sentence: "Septicæmia has not been quite banished, but much has been done in this direction, *as shown by one consecutive series of 100 ovariotomies performed at the Samaritan Hospital without a death.*" That statement of results has been publicly quoted in its most evident sense—viz., that there were 100 consecutive cases *without a death from any cause*. This has been corrected in the report which you have published, but in such a way as to escape the notice of any but a critical reader, by the simple addition of the words "from septicæmia." I desire therefore to call attention to this correction, and to remove an erroneous impression.

I am, Sir, yours faithfully,

GEO. GRANVILLE BANTOCK.

Granville-place, W., Nov. 2nd, 1886.

BIRMINGHAM.
